INDEX TO VOL. XIX.

A.

ABERDEEN, exhibition of, 1869, 222
Abyssinian expedition, water supply, 295
Abyssinia, science in, 287; telegraphic communication with, 43
Accidental death, 212
Accident, the statistics of, 278
Acland, an improved method of dividing thermometers, 221
Adjustable Belgravia sewing machine, 85
Admiralty, the, 81
Aerated waters, machine for manufacturing, by J. Matthews, 208
Aerial locomotion, 290, 307, 347
Aeronautics at the Crystal Palace, 338, 376
Aeronautical Society of Great Britain, 105, 217, 254, 278, 298
Africa, a new expedition to, 409
Air-compressing engine, by J. G. Lloyd, 108
Air pump, the Sprengel, 86
Alabamas of the U.S. navy, the new, 337
Alley's radial drill, 296
Alleyne's puddling furnace, 73
Alloys and their uses, by Professor Matthiessen, 298
Alloys and quasi alloys, 403
American blowing engine, an impromptu, 168
American coal, 395; dovetailing machine, by S. T. Armstrong, 89; locomotives, 394; the proposed Naval Board, 84; ordnance, 137; small arms, 176; tube well, 216
Anæsthetic, a new, 274
Anemometer, the, and the recent gales, 123
Anderson, Dr., on the gas-producing quality of Trinidad petroleum, 14
Apparatus for burning hydrocarbon oils, 8; for finishing parts of locomotive wheels, 270; for the manufacture of watered fabrics, by M. Tavernier, 167
Architecture, naval, 1
Arctic expedition, 9
Armour, 2
Armour-clad ram, the new Dutch, 222
Armour-plates, trials of, 216; trials of a 10-inch, 105
Arms, small, 2
Army, cooking for the, 327
Atlantic telegraph, 196
Artillery experiments at Fortress Monroe, 13

B.

BAILEY'S steam engine, 129
Bar-testing machine and callipers, improved, by John Page, 199
Bars, twisted, 261
Battersea, new railways at, 9
Beet-root sugar, on the manufacture of, in the United States, by J. Birkbeck, 181
Belgium and France, manufacturing and mining industries of, 385
Belgravia sewing machine, the adjustable, 85, 432
Berlioz's magneto-electric signal lights, 30
Bessemer steel, moulds for casting, 88; steel rail ends, machine for utilizing, 274
Bessemerizing and the nitrate steel process, 128
Binney, E. W., on the age of the hæmatite iron deposits of Furness, 10
Bland, E., improved gridiron, 106
Board of Naval Survey bill, 260
Boiler Association, Manchester, 52, 89, 356, 454; assurance company, Midland, 255; insurance company, National, 295; insurance company, the, 333; special steam, 332; tubes, and Wood's improved method of fitting, 109
Boilers, cast-steel, 242
Boiling down, 467

BOOKS, NOTICES OF

Artizans' reports of Paris exhibition, 46
Bourne on the steam engine, 232
Electrical measurement, by L. Clark, 366
Engineer and architects' directory, 446
Engineering facts and figures for 1867, 269
Etudes sur L'Exposition Universelle, 1867, 178
Fairman on petroleum zones of Italy, 270
Geometry, practical, plain and solid, by W. Hudson, 233
Gold currency, a, for India, by Col. J. T. Smith, 178
Gray, T., on the value of coloured side lights as a means for preventing collisions at sea, 104
Handbook of practical telegraphy, by E. S. Culley, 445
Haughton, S., on French railways, 104
Insurance guide and handbook, by C. Walford, 103
Iron, works in, by Andrew Handyside and Co., 426
Journal of the institute and assurance magazine, 104
Latham, B., on the purification of sewage, 46
Modern screw propulsion, by N. P. Burgh, 232
Practice of engineering fieldwork, &c., the, by A. D. Haskoll, 406
Principles, the, that govern the future development of the marine boiler, 233
Rain, by G. J. Symons, 47
Railway service, the, by W. F. Mills, 178
"Rob Roy," the voyage alone in the yawl, 46
Strachan, R., on the principles of weather forecasts and storm provisions, 46
Sun views of the earth, by R. A. Proctor, 104
Telford, Thomas, the life of, by Samuel Smiles, 46
Telegraph, practical electric, by Rev. T. Cooke, 233
Timbs' year-book of facts, 269
Treatise on coast defences, by Von Scheliha, 365
Tyas on the weather glass, 47
Watts' dictionary of chemistry, 270

Bowstring girders, 232
Break, power, 10
Breechloading arms, American, examination of, 472; rifles, 231
Brewster, Sir D., death of, 122
Brickmoulding machine, 431
Bridges, long *versus* short span, 267
Bridge over the Rhine at Mainz, 351; the solid lever, 487
British army, the, 319; horological institute, 148, 385
Brothers, A., on the colour of the moon during eclipses, 10
Brougham, Lord, 365

C.

CALLIPERS, improved, 185
Calcutta, brickwork in, 487
Carbon, effects of, on electro deposition of silver, 250
Cargill on application of town sewage, 429, 453
Carpets, printed tapestry, manufacture of, 428
Carriage axle, Watkins, 13
Carr's disintegrator, 411
Casella's pocket altazimuth, 355
Cask stand, new, 375
Cast metal, producing a vitrified surface on, 395
Cast-steel boilers, 242
Central horticultural society, 409
Centrifugal pump, hand power, by Joseph Bernays, 35
Chains, traction and suspension, links for, 236
Chain tugboat on the Pajane, Crighton and Co., 316; weldless, 33
Chancery, court of, patent cases in, 81
Charcoal, animal, improved method of treating, 53
Chassepot rifle, the, 12
Chemistry, 3; on some recent improvements in analytical, 44
Civil engineers, institution of, 48, 66, 105, 125, 142, 186, 202, 272, 295, 312, 336, 355, 389, 404, 424
Circular malt kiln, 395
Circle marker, 53
Clouds and sky, colour of, 31
Coalfields, the upper, of Port Natal, 137
Coal, utilizing waste, 204; Welsh steam, 487; small, utilization of, 490
Coast defences, 365
Cobra, the poison of, 72
Coinage, the silver, of Great Britain, 250
Colour, origin of, 260
Combined anvil and press, 390
Competitive gun carriage trials, 5
Composite ships, 249
Concrete stone fountain, 34; stone, patent, in Australia, 130
Converting gaseous products into combustible gases, 317
Cooking for the army, 327

CORRESPONDENCE:—

Aniline black, 113
Combined floating dock and battery, J. G. Winton, 396
Carrett and Marshall's pumping engines, Carrett, Marshall and Co., 205
Circle, the, squaring of, 17
Circle, the square of, and the great pyramid of Gizeh, W. Harvey, 17, 73, 130, 151, 168, 186, 223
Ellipse, method of drawing an, 74
Fracture of axles and boiler plates, C., and M. E., and Electrician, 205
Fortresses, suggestions for the defence of, G. J. Gunther, 150, 168, 300, 320
Flow of water, 75
Giffard's injector, 75
Heat, 74
Hurricanes, on defensive measures against, 37
Intensity of cold, 113
Lincoln Waterworks Company, H. Teague, 376
Magnetic phenomena, A de B., 435; J. B. Dancer, 455
Notes on our navy, 475
Patent-office library, J. T. Dexter, 261
Peroxide of manganese battery, J. H. Williamson, 338
Petroleum as a fuel, 37; furnaces, 75
Preserving gutta-percha, An Explorer, 357
Russia, machine manufacture, A. Cameron, 280, 434, 474
Squaring the circle, J. Stapleton, 243; Commander, R.N., 131; Nicholson, 37, 54, 94, 112, 131, 151, 168, 187
Speed of the "Waterwitch," W. Frew, 205
Town refuse practically utilized, 490
Well-boring in Abyssinia, 113
Corks, machinery for cutting, J. W. Dudley, 296
Crane, hydraulic, improved, 254
Crighton, W. and Co., chain tugboat on the Pajane, 316
Crystals containing fluid, by J. B. Dancer, 111
Crystal palace, 84, 123
Cuba and Florida cable, 423

D.

DANCER, J. B., on the microscopical examination of the air of Manchester, 369
Dardanelles cannon, the, 394
Davey, on the isochronal governor, 144
Deepening of the Michigan and Illinois Canal, S. W. Robinson, 357
Differential saturometer, 194
Dock, new graving, for Glasgow, 34
Docking an ironclad, 396
Docks, Millwall, opening of, 222
Dockyards of the Mediterranean, 158, 139
Donaldson, Professor, on the railway terminus of the Midland railway, 371
Double-action self-acting steam hammer, 13
Dovetailing machine, American, by S. T. Armstrong, 90
Drill, improved hand, 65
"Dyrad," H.M.S., return-acting screw engines of, 10

E.

ECLIPSE, the great preparations to photograph, 214
Elasticity in railway stock and the track, 468
Electric current, molecular vibrations caused by, 63; dynamo-electric apparatus, by C. W. Siemens, 88
Electrical communication in trains in motion, 213; tests of recent submarine telegraph cables, 313; thermometer registering, 83
Electricity, frictional, 196; and telegraphy, 23, 45, 64, 102, 121, 178, 233, 253, 330, 349 406, 486
Electro-metallurgy, 3
Electroplastic, 26
Electrotyping, new application of, 121
Engine, express, Great Northern, 217; fast passenger, by M. Borsig, 183
Engines for the Weardale and Shildon waterworks, 147; of H. M. sloop of war "Sappho," 430; of the "Great Eastern" steam launch, 238
Engineers, London association of foremen, 34, 112, 143, 198, 278, 356; society of, 5, 110, 148, 165, 182, 220, 240, 258, 275, 296, 404, 444; mechanical institute of, 354
Engineering, mechanical, 1
English and French lenses, 426
English photographic lenses, 363
Exhibition, the aeronautical, 485
Explosions, colliery, 83
Exports of railway iron, 394; of machinery, 204
Eyes of metal workers, protection of the, 214

F.

FABRICS for dyeing or printing, treatment of, 92
Fans, improvement in, 428
Filing machines at Stamford-End Works, by G. Wilkinson, 257
Fire engine, steam, for Shipley, 167
Fire and fire engines in Paris, 168
Fish, gourami, the, 130
Fittings in English and foreign hospitals, 280
Floating water-wheels for Siam, 467
Fortifications, 449; the experimental, at Shoeburyness, 176; Fraser guns, metal for, 121
Force of impact, 120
Fox, Mr. C. D., on new railways at Battersea, 9
French imports, 434
Friction coupling brake, by T. A. Weston, 126
French monitor, "Onondoga," the, 27

G.

GALE, J. M., C.E., on the Port Glasgow waterworks, 318
Gas engine, improved, Kinder and Kinsey's, 277
Gas engineering, 3, 318; lighting, new system of, in Paris, 62; pressure in cities and towns, 175; supply, London, 137
Gases, liquefaction of, 483
Gearing, improved pulley and chain, 236
Geographical society, royal, 203
Genius, unappreciated, 92
Gibraltar shield and the 10-inch gun, 107
Gladstone, Dr. J. H., on some new experiments on light 408
Gold discovery in South Africa, 295; toughening, 145
Gourami fish, the, 130
Governor, improved, 259; the isochronal, by H. Davey, 144
Government breech-loading revolver, 372; and the telegraph, 159; telegraph bill, 288; and the telegraph companies, 345
Grain cleaning machine, by A. Mather, 180
Granite, artificial, 487
"Great Eastern" steam launch, engines of, 238
Greek fire, practical notes on, by J. Horsley, 159
Gridiron valve, improved, by E. Bland, 106
Gun, the accelerator, by A. S. Lyman, 124; barrels, boring machine for, 50; carriage, competitive trials, 5; new muzzle-loading field, 149; the Palliser, 166
Gunboat, a novel, 242; "Staunch," 351
Gunnery experiments at Shoeburyness, recent, 119, 463, 483
Guthrie, Dr., on a new form of voltameter and voltastat, 434

H.

HÆMATITE, age of the iron deposits of Furness, by E. W. Binney, 11
Handel festival, 249, 487
Hammer, dead-stroke power, by Shaw and Justice, New York, 165; double-action self-acting steam, 13
Harbour works in the north, 269
Hargreaves on the manufacture of malleable iron, 86
Harp and violin strings, 92
Hartley institution, progress of the, 34
Havre international maritime exhibition, 87, 215
Harvey, W., on the square of the circle and the great pyramid of Gizeh, 16; torpedo, the, 231
Heat without coal, 69
Higgin, G., on irrigation in Spain, 374
Holmes, F., treble-action pump, 91
Hoosac tunnel, the, 34
Horticultural society, the royal, 280
Hospitals, English, foreign fittings in, 280
Hot-blast stove at the Thornaby works, 127
Hungary, the industrial enterprise of, 104

Digitized by Google

I.

IMPERIAL establishments on the Loire, 423, 465
Imports, French, 434
Indo-European telegraph, 484
Insubmersible lifeboat, by H. W. Withers, 147
Iron cables, manufacture of, at Guerigny, 241
Iron, cast, on the shrinkage of, 235
Ironclads, forms and proportions of, by E. J. Reed, 284
Ironclad frigate, "Wilhelm I.," 239; ships, 259
Iron forts and heavy guns, 259; the hæmatite, of Scotland, 167; the manufacture of malleable, 86; new process for coating with brass and silver, 444; and wood, composite, securing in ships, 201
Irrigation in India, by T. Login, 356; in Spain, by G Higgin, 374

J.

JERUSALEM and Sinai, surveys of, 433

K.

KINDER AND KINSEY'S improved gas engine, 277

L.

LAMP, chimneys, 299
Landscape photography, 195
Launches, recent, 336
Leeds association of foremen engineers, 69

LEGAL INTELLIGENCE.

Society, acclimatization, of London v. Royal Zoological Society, 168
Attorney-general v. L. Edmunds, 416
Bovill v. Hitchcock, 54
British Columbia Saw-mill Co. v. Nettleship, 320
"Great Eastern," the, 54
"Lion" judgment, the, 338
Platt and others v. Higgins, 54
Webb v. Rennie, 357
Lifeboat, insubmersible, 147; steam cutters, 121
Light, artificial, in photography, 465
Light, on some new experiment on, by J. H. Gladstone, Ph.D., 408
Light, theory of, 260
Lighting the Euston-square station, 316; new system of, 54
Lime light, the, 274
Link, patent safety, Ormerod's, 293
Lithology of the British Isles, 188
Liquid meter, Payton's, cycloidal, 109
Livingstone, Dr., 34, 61, 168
Lloyd, J. G., air compressing engine, 108
Locomotives in their daily working, 35
Login, T., on irrigation in India, 356
London gas supply, 137
Looms, improved, for weaving, by R. Carter, 468
Lubricator, Schloesser's, 124
Lyman, A. S., the accelerator gun, 124

M.

Machinery, exports of, 204
Machine for manufacturing cutters and milling tools, 219
Magnesium, a new method of producing, 309
Magnetic phantoms, 267
Malta water supply, 35
Malleable iron, certain points in the manufacture of, by St. John V. Day, 388, 414, 432
Malt kiln, circular, 395
Manufacturing and mining industries of France and Belgium, 385
Marine governor, four ball, 314
Matthiessen, Professor, on alloys and their uses, 298
M'Culloch's microscope, 409
Mechanical engineering, 1; engineers, institute of, 106
Mee's hose coupling, 198
Metal for Fraser guns, 128
Metal, what is a? what is a metalloid? 229
Metallic tubes, ornamental, manufacture of, 473
Meteorology, 4
Meteorological investigation, 465
Metric system bill, 431
Microscopical society, royal, 10, 295; examination of the air of Manchester, by J. B. Dancer, 369
Midland railway station, St. Pancras, 371, 444, 452, 471 490
Millwall docks, opening of, 222
Milroy's excavator, 393
Mines, the mechanical ventilation of, 29
Miner's safety lamp, by D. P. Morison, 93
Mint, the "Times" on, 194
Miscellanea, 17, 38, 55, 75, 95, 113, 131, 151, 170, 187, 205 223, 243, 261, 281, 301, 321, 339, 358, 377, 397, 417, 435, 456 476, 491
"Monarch," launch of the armour-clad turret-ship, 408
Moncrieff's gun carriage, 395, 469
"Monongahela," loss of the United States ship, 28
Monroe fortress, artillery experiments at, 14
Moon, colour of, during eclipses, by A. Brothers, F.R.A.S., 10
Mortars for mountain warfare, 49
Mules for spinning and twisting, 304
Museum, South Kensington, 16
Muzzle pivoting gun carriage, 316

N.

NAPOLEON III. on the voltaic pile, 128
National artillery association, 389; intercommunication, 229; rifle association, 369
Nautical terms, 236; nautical compasses, improvement in, 273
Naval architecture, 1; architects, institution of, 271, 289, 309, 329, 346; military, and gunnery items, 17, 38, 55, 75, 95, 113, 131, 151, 169, 187, 205, 223, 243, 261, 282, 301, 321, 339, 358, 376, 396, 416, 435, 456, 475, 491
Navies, English and French, 69
Navy estimates, the, 203, 403; notes on our, 311, 386
Newton, Sir Isaac, the portraits of, 237
Nut-shaping machine, by Messrs. Kendall and Gent, 129

O.

OAKUM, manufacture of, 186
Obituary, 36, 186, 280, 365
Observatory, the Paris, 14
Odling, W., on some effects of the heat of the oxy-hydrogen flame, 455
Oils, hydrocarbon, apparatus for burning, 8
Oil tester, Ingram and Stapfer's patent, 185
Ordnance, 2; American, 137
Ormerod's patent safety link, 293
Ovens, portable and stationary ovens, 334
Oxy-hydrogen flame, on some effects of the heat of, by W. Odling, 455
Ozone, presence of, in the atmosphere, 363

P.

PAPER, new uses of, 181
Parliamentary notes, 141, 161, 197, 367, 348, 407, 467
Paris, the observatory, 14
Patent cases in the court of Chancery, 81; concrete stone in Australia, 130; office, the improvement of, 432
Payton's cycloidal liquid meter, 109
Past, the, and the future, 1
Peat fuel, 72, 82, 295
Peet's patent valve, 198
Pencil lead mines and lead pencils, 409
Peroxide of manganese battery, 203
Petroleum, Trinidad, on the gas-producing quality of, 14
Photography, 4, 26, 44, 64, 85, 122, 140, 160, 178, 195, 330, 387; as an art, 443; artificial light in, 465, 485; landscape, 290; in the printing press, 308
Photographic apparatus, imperfections in, 101; process, improved, 143; lenses, English, 363; societies, the, 231
Pigs, Mr. Seeley's, once more, 217, 242
Pellet gunpowder, 260
Pneumatic apparatus for signalling on railway trains, by Mr. L. Clark, 51; dispatch, improved system of, by C. W. Siemens, C.E., 31; rubber buffer and draw springs, 449
Pneumatics, surgical, 7
Pocket photographic camera, 355
Poison of the cobra, 72
Polytechnic institution, 186, 291
Ponton, photographic researches, 252
Port Glasgow waterworks, by J. M. Gale, C.E., 318
Portable pumping engine and boiler, by Brown and Wilson, 182
Printing press, photography in, 308; the Minerva, by Mr. Cropper, 71
Printing without ink, 294
Propellers, theoretical limit of the efficiency of, by W. J. M. Rankine, C.E., 315
Public conveyences, improvements in, 345
Pump buckets, new system of, by Mr. Jacob Bird, 33
Pump, treble-action, by F. Holmes, 91
Punching machine, portable, 255
Puddling, economy in, 184

Q.

QUEKETT microscopical club, 93
Queer periodical, a, 138

R.

RAILS, machine for cutting up, 274
Railway accidents, 63; American constructor, 61; carriage lock, 15; bridge at St. Louis, 273; reform, 25; rolling stock of the United Kingdom, 85; stock, and the track, elasticity in, 469; wheels, suspended, 447
Railways, new, at Battersea, 9; suburban, 211; and their management, 217, 250
Rain gauges, 68
Ramsbottom and Pearce's improved turbines, 15
Radial drill, Alley's, 296
Ranegunge pottery works, 411
Rangoon, remarkable phenomenon at, by Dr. C. Collingwood, 47
Rankine, W. J. M., C.E., LL.D., on the theoretical limit of the efficiency of propellers, 315
Reefing topsails, new method of, by Captain Webb, R.N. 319
Reaping machines, cutter for, 92
Reilly-Comblain rifle, 375
Restaurant, marble, 473
Rifle, the Chassepot, 12; the Wilson, 185
Rifles, breechloading, 231
Robinson, S. W., on the deepening of the Michigan and Illinois Canal, 357
Rochussen's permanent way, 162
Roofs, strains in, 85
Royal Agricultural Society, 329; Cornwall Polytechnic Society, 447; Botanic Society, 467; Geographical Society, 72, 472; Horticultural Society, 355, 427; Institution, 354, 369; Microscopical Society, 10, 222; Naval Engineers, the, 139; Society, soiree, 199, 327
Runcorn, great bridge, the testing of, 426

S.

SAFES, the battle of, 119
Safety catch, self-acting, 355
Safety gun cotton, 384; lamp, by D. P. Morison, 93
Salt in France, 443
Salts, ferruginous, utilizing, 87
"Sappho," H.M. sloop of war, engines of, 430
Schloesser's lubricator, 124
Scientific discoveries, recent notes on, 27, 47, 65, 102, 123, 161, 179, 215, 234, 270, 291, 311, 331, 348, 367, 388, 407, 427 446, 465
Scientific education, 73; ratcatching, 351
Screw pressure pipe jointing machine, 390
Search for solid bodies in the atmosphere, 333
Sewage, the disposal of, 43, 474
Sewing machine, the Belgravia adjustable, 433
Shields, the Gibraltar, 53
Shipbuilding on the Clyde, a year's, 31
Ships, composite, 249; of war, cost of, 211, 443
Siam, floating water wheels for, 467
Siemens, C. W., dynamo-electric apparatus, 88
Silicated carbon filtering tap, 73
Silkworms' eggs, 447
Silver coinage of Great Britain, 383
Silver, electro, deposition of, 250
Slag, utilization of, 186
Slide rule, improved, J. Noble, 427; valves, new method of constructing, by N. W. Wheeler, 68

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 3, 1868.

THE PAST AND THE FUTURE.

IN commencing the Eighty-eighth Volume of the MECHANICS' MAGAZINE, let us first tender our thanks to the public for the liberal support which has been accorded to us during the past forty-five years. This period has witnessed vast progress in the practical application of science, and the last few years have testified to a wonderful expansion in this direction. Although an outline of the history of this journal has recently appeared as a notice in our columns, as well as an intimation of the improvements to be introduced, it may be as well briefly to refer to those matters again, as we are happy to record an accession of new subscribers. The MECHANICS' MAGAZINE first appeared in 1823, a small pamphlet as compared with the present issue. In 1859 Science had so progressed as to oblige us to double its size. To keep pace with the times we were again obliged, three years since, to enlarge its size and to increase the number of its pages, and we now find it necessary to further increase the number of pages, as in the present issue, which increase will be repeated from time to time, as circumstances may require. The patent interest will continue to form the chief feature of the MECHANICS' MAGAZINE, and an increased number of illustrated descriptions of inventions will regularly appear. Besides this it will be our aim to keep our readers informed upon the most recent mechanical improvements, or, in other words, to carry them from Theory into Practice, from the Patent Office where the ideas of inventors are fostered and nurtured, to the foundry, workshop, and factory, where these ideas become developed into facts. The arts and sciences are now represented by gentlemen practically skilled in each special department, and by a thorough re-organization of our staff we shall be enabled to keep our readers thoroughly informed upon every subject of scientific interest. We commence with new paper and type, and our journal will be found to be improved in many other respects, not the least of which is the double page engraving we this week present to our readers, and which will be repeated as appropriate subjects offer themselves for illustration.

Having said this much for ourselves, let us now proceed to follow our annual custom and place before our readers the main events in science during the past year. We will also follow the subject a little farther, and endeavour to indicate the probable course of scientific research, and the possible results which may be expected during the year now opening upon us. First, then, as to the past. Looking generally at the year just closed we cannot record any brilliant scientific achievement or the accomplishment of any great engineering success. The plain truth of the matter is that trade and commerce have not yet recovered from the severe checks they experienced in 1866, and which have been added to not a little during the past year. Commercial prosperity underlies practical scientific progress, and when commercial failures and monetary panics occur they are sure to influence the advancement of science, which is so dependent upon capital for its practical development. But although science—and engineering science especially—has been so checked and retarded, we are happy to see that there are general signs of amendment, and it is to be hoped that with the coming spring, and a return of commercial confidence, we may soon see our engineering establishments in full and active work again. These once set going, and legitimate enterprise again vigorously pushing onward, progress will extend to all around, and prosperity will follow in its wake.

MECHANICAL ENGINEERING.

IN the department of mechanical engineering attention has been given during the past year to the perfecting of rock-boring, and coal-cutting machines. In view of the important works in tunnelling now being carried out, or in contemplation, it is well that no opportunity should be lost to improve the means of facilitating the progress of these tedious and expensive operations. With regard to coal-cutting machines, it is of the first consequence that our present coal supply should be maintained without increased cost either to the producer or the consumer. The increasing depth of workings renders it necessary that labour should in some way be both cheapened and economized. The coal-cutting machine does this most effectually, and something more, for those in which compressed air is used greatly aid the ventilation, and render work in coal mines both lighter and more healthy. We are glad to observe that a movement is on foot to give prizes for the best machine of this class. This step will greatly assist in the development of this application of mechanical science. No great or special features present themselves here for notice, unless we except the engines by Messrs. Penn for the "Hercules," and those of the "Inconstant" of 1,200 and 1,000-horse power respectively. These were described in the MECHANICS' MAGAZINE for September 20 last, and are only now referred to as features of the past year's work. A very useful centrifugal pump has been brought out by Mr. Bernays, in which the revolving fan is entirely relieved from the pressure of water on its outer surface. Friction and, consequently, wear and tear, are thus greatly reduced, less power is absorbed, and the pump may be driven at a lower speed than the ordinary centrifugal pumps with full effect. The subject for adapting locomotives for working steep gradients, has also received some attention from Mr. Thomas Page, C.E., who uses a broad driving wheel, biting into a roughened stone tramway. So far as experiments go, this system answers well, but the test of practice has yet to determine its value. Meanwhile, we have undeniable evidence of the success of Mr. Fell's system on the Mont Cenis Railway. Mr. Fell uses a central rail, which is gripped by four horizontal wheels, and from which great adhesion is obtained. Looking forward, we may anticipate in the ensuing year some further improvements in the machinery we have already noticed. Serious attention, however, should be given to mining engineering. Remembering the calamities which have occurred during the past year, it is incumbent upon all interested in mining property to see that a greater degree of immunity is secured for the future, by the adoption of proper preventive means, and our engineers will do well to give their attention to improvement in this direction. The economy of fuel in the steam engine and in the arts and manufactures, is another important point to which the attention of engineers should be directed, as, owing to the limited extent of our coal fields, there is a certainty that the time must come when coal will be costly to produce, however much that period may be deferred by the aid of machinery.

NAVAL ARCHITECTURE.

UNQUESTIONABLY shipbuilding has presented greater features of novelty and interest during the past year than are to be found in any other direction. The principal activity in the trade has taken place in connection with the production of war vessels. The cessation of the American war, which created a demand not only for vessels of extraordinary speed, but for vessels possessing this quality in combination with a light draught of water and great fuel-carrying powers, threw a great many vessels of this class upon the hands of merchants. In most cases they were built of steel, and of scantlings so slight as to excite astonishment even in the most daring professional minds. Many of these vessels have been purchased during the past year by the Turks and by the Greeks, for use in connection with the Cretan rebellion, and it is a noteworthy fact that two of these vessels have been destroyed, or nearly so, by explosions—that of the Turkish Government, built and engined on the Clyde, having burst her boiler abroad, and that of the Greek Government having met with a somewhat similar fate on the Mersey. None of these vessels were, however, war-ships proper, but were blockade-runners, converted, so far as was practicable, into armed craft.

Among real vessels of war built or finished during the year by private firms for foreign governments may be noticed the Danish turret ship "Prince Hendrik," built by Messrs. Laird for the Dutch Government; a turret ship and a Monitor now building by Messrs. Napier for the same government; a small broadside ship just launched by the Thames Company for the Greek Government; the frigate "Crown Prince," built by Messrs. Samuda for the Prussian Government; and the "William I.," building by the Thames Company, also for the last-named government. All these ships are armour-clad. The "Prince Hendrik" is chiefly remarkable from the fact that she is a "belt and box" ship, with a turret standing up through the top of the armoured box, the ship being completed at both ends by unplated extremities coming up flush with the top of the box, as in the "Pallas," "Bellerophon," "Enterprise," and most of Mr. Reed's ships, and a short forecastle being fitted forward. By the adoption of these devices a much greater height of freeboard than the "Scorpion" and "Wivern" possess is obtained, and the "Prince Hendrik" will no doubt prove possessed of much superior sea-going qualities to theirs in the ordinary acceptance of that term. Her armour, however, is almost as slight as theirs, and her speed is 12 knots. The turret ship of Messrs. Napier is without the "box," and more resembles the "Affondatore" as regards the protection of the bases of the turrets with armour. The Monitor is more of the American type of ship. The little Greek broadside or end-on ship just launched at the Thames Works is a remarkably well-designed little vessel, having very thick armour for her size, and the promise of good speed. It is exceedingly improbable, however, that she will fairly attain the high contract speed of 14 knots loaded for sea, notwithstanding the improvements introduced into her engines; and it must be said that her battery is very confined, and her draught of water several feet more than the smallest iron-clads of the Royal navy. We have great confidence, however, in this proving a very efficient and powerful little ship. The "Crown Prince" is undoubtedly a great success as a ship of the "Bellerophon" type, on dimensions less than those of the "Bellerophon," and with thinner armour. She is a very fast and very handy ship, and shows that Mr. Reed was perfectly correct in denying that an iron-clad must necessarily be of extreme length and unwieldy in action in order to steam fast. She reflects great credit on Messrs. Samuda, and upon the makers of the engines, Messrs. Penn, and will be a valuable ship to the Prussians. But the "William I." will be still more valuable, as she ought to be, considering her size and cost, for she will be, when launched, the most powerful iron-clad afloat in the world. Her armour is 8-in.; she will carry about 30 heavy guns, some of those on the upper deck, as well as those on the main deck, having armour to protect them, and possessing a range of fire all round the horizon. She will steam at nearly 15 knots, and will therefore probably be the fastest as well as the most powerful of iron-clads. She was designed for the Sultan of Turkey by the

Digitized by Google

Chief Constructor of our navy, but has passed into the hands of the Prussians.

In our own navy the past year has been a most eventful one. We have made great progress with the "Hercules," a ship in some respects superior, although in others inferior, to the great Prussian ship. In her we shall have an iron-clad invulnerable at least at the water-line, with 18-ton broadside guns, and an enormous bow fire; with a full-rig, a high speed, a great handiness, together with Captain Scott's excellent mechanism for revolving and otherwise working the guns carried out under his own eye. We have also made great progress with the Admiralty turret ship "Monarch," which Captain Coles deems a mockery of his plan; and fortunately Messrs. Laird have pushed along as rapidly with the "Captain," which is to be the perfect embodiment of Captain Coles' ideas. These two ships will, we trust, be got to sea together next year. Nor are these all the turret ships laid down by the Government, for Messrs. Palmer, of Jarrow-on-Tyne, are building a powerful iron-clad turret Monitor for the ort of Melbourne upon a new plan, designed by the Chief Constructor, in which the turrets, instead of standing upon the low open deck, American fashion, spring from the armour-clad breastwork, covered by a deck 8 feet higher, through which all the hatchways pass, the object being, of course, to give greater security to the ship against loss by sinking. In other respects the turrets are on the plan of Captain Coles. It may be interesting to add that Messrs. Napier are building two other iron-clads for our Government, and Messrs. Laird a third, and a fourth is being laid down at Pembroke Dock, the principal features of these ships being the possession of twin screws, and of an armour-plated upper deck battery, projecting over the side, and commanding a direct fire sight, right astern, and all round the horizon. Twin screws are also adopted in the Melbourne Monitor, and in the composite gun-boats about to be mentioned.

The past year has been marked also by the adoption by the Admiralty of the composite system on a large scale. A whole fleet of twin-screw gunboats, with iron frames and two layers of wood plank, are being built in the Royal dockyards, and in various private yards, the first of them being tried under steam at the time we write. This vessel is named the "Beacon;" she was built at Chatham, and was subjected, soon after launching, to a most severe trial of her strength by the bursting of the caisson at the entrance of the dry dock in which she lay. The manner in which she stood the ordeal of being dashed bodily against the masonry of the dock showed that she is thoroughly well constructed and fastened. One peculiarity of her fastenings consists in the screws of the inner layer of plank being tapped through the frames themselves.

Another form of composite construction is being carried out by the Admiralty in the "Inconstant," "Volage," and "Active," three fast unarmoured ships building, the first at Pembroke dockyard, the other two at the Thames Iron Works. In all these ships an iron skin is being first worked over the frames, and the doubled strakes of teak are worked upon it, and fastened to it. They are, therefore, iron ships sheathed with wood, but differ from ordinary iron ships, of course, at the bow and stern. These ships are very bold experiments, and the efficient adaptation of their long and fine sterns to receive the powerful action of their screws without setting up galvanic action, will tax all the ingenuity of Mr. Reed and his staff. Such ships are great and valuable experiments, and the Admiralty deserve credit for such bold endeavours to combine the structural strength of iron with the advantages of a coppered bottom in our fleet vessels of war.

The Admiralty work of the year also includes the production of the most important fleet of passenger steamships ever produced. The new Indian steam transports, which are now in the full swing of their work, have proved successful in the highest degree and in every respect. These ships presented many unusual difficulties in their design, and Mr. Reed may certainly claim credit for having overcome them completely. But few vessels of note have been added to our large mercantile steam fleets during the past year, but the "Sumatra," built by Mr. Denny, of Dumbarton, for the Peninsular and Oriental Company, deserves mention as a good, commodious, and economical steamer.

In the coming year, we fear, the shipbuilding trade must not be looked to for any great advances. So far as its probable extent is concerned, there is reason to apprehend depression, and in times of commercial and trade depression it would be vain to look for extraordinary enterprise. It appears likely that the scheme for transporting railway trains across Lake, Lucerne upon which Mr. Scott Russell is engaged, will be carried out, but we fear that little or no progress will be made with the similar scheme contemplated for the Straits of Dover. Nor do we find any ground for hoping that the wretched little steamers which now constitute our sole means of reaching the Continent will be replaced by better vessels, owing mainly, no doubt, to the harbour difficulties on the French side. In the Royal Navy, for which ships are continually being built, there is always room for progress, and there never was greater inducement to move forward than at present. What we hope to see during the coming year is the commencement, at least, of a combined broadside and turret ship of high speed, plated with at least 12-in. armour, and armed with the heaviest obtainable guns. Nothing short of this ought to satisfy the nation at a time like the present.

ORDNANCE.

WE find nothing very striking to record in gunnery matters during the past year. The guns have maintained their superiority over the targets, but this only by the aid of Major Palliser's chilled shot. The exception, perhaps, would be the American 15-inch cast-iron gun, which has been experimented with, and has put spherical shot through a considerable thickness of plating. But the vast superiority of this gun over our own remains yet to be developed. It is true that it has fired 100lb. of powder, but not many times yet. And upon this point, Admiral Farragut is reported to have said, "Ah! you may fire 100lb. of powder if you like—*we don't.*" It is satisfactory, however, to have tried this gun, but we have yet to learn its great practical value. The Fraser gun has been perfected, and is now being turned out at Woolwich, a very perfect piece. Major Palliser, too, has not been idle with his system of converting old cast-iron guns into useful rifled ordnance. The major is now engaged in some experiments with a converted gun, which, so far as they have gone, have given very good results. When these experiments are completed, we hope to place them before our readers. Mr. Parsons also is engaged in converting a cast-iron smooth bore into a rifled piece. This gentleman's system is in the main similar to that of Major Palliser; the details of the process of conversion, however, differ. From the success which attended the trials of a French gun converted on Mr. Parsons' plan, as well as from the soundness of the system itself, we anticipate good results.

As there is a great similarity between the systems of Mr. Parsons and Major Palliser, we suggest they should amalgamate and work out their ideas to perfection conjointly for the benefit of the country—taking care, of course, that they were benefited in return, But in the year before us, we think a fair opportunity should be given to each of those gentlemen to prove the value of his system of conversion. Let two guns of equal weight and calibre be converted upon the two systems under conditions as nearly equal as possible, each to the satisfaction of the inventor. Then let these guns be fairly tested, and the question as to which is the superior method of conversion would be set at rest, and one or other of the inventors need not trouble himself farther—in England, at least. But a still more important question, which should be pursued to a satisfactory conclusion during the coming year, is whether we want converted guns at all. They are like the converted rifles, very useful until we have a perfect weapon produced. They answer a certain purpose very well, but, at the most, are but a stopgap, and a makeshift. The converted guns, like the rifles, will always be found useful in one direction or other, but for general service we must have a sound reliable gun. The economy of the Fraser gun, and the simplicity and soundness of its construction, point it out at present as the gun of the future. The Mackay gun has been doing good work at Crosby, and although only roughly mounted on balks of timber, its performances were of a very high character. Mr. Mackay's gun should not be neglected; the Government ought to lend a helping hand to develope a system which evidently possesses great merit. We hope attention will be given to this gun by the authorities in the year before us.

ARMOUR.

THE great event of the year in the matter of defences has been the production of the largest armour plate ever rolled. Four years since the production of a 6-inch armour-plate was regarded as a great achievement. Four months since, however, an armour-plate 15in. thick, 20ft. long, 4ft. broad, and weighing 20 tons, was successfully rolled by John Brown & Co., of Sheffield. The production of this plate has had the effect of stopping the progress of the iron-clad fort system as at present designed with its 5-in. armour plating and two layers of 5-in. iron bars. This system of construction is of course far inferior to the solid, inasmuch as 8in. of built-up plates are not equal in resistance to 4½in. of solid. But such a system was necessary when no solid plate of the required thickness could be had. Now, however, there is no excuse for Government not using the best means of defence. Sir John Brown has met all the requirements of substance, and as the plate is now under test we shall no doubt soon hear that he has met those of quality as he always has done. The price will not be materially increased when large quantities are required, so that if the quality turn out well, there will be no reason why these plates should not be adopted in the fortifications of the future. At the same time we should not stop here, but carefully pursue the investigation of the principles which govern the resistance offered by armour-plates to projectiles. At the present time, Major Palliser's chilled shot and shell have turned the tide of victory in favour of the guns. To reverse this condition of things we must improve our armour-plates, not so much, however, by increasing their thickness; for however thick we can make a plate, we can always make a gun powerful enough to penetrate it with a proper projectile. We must bring science to bear upon the question, and try whether by a new combination of the component parts of the target, or by a peculiar arrangement of the fibres of the iron in the plate, we cannot stop out shot and shell without resorting to a thickness of metal which would virtually prohibit its application as a means of defence.

SMALL ARMS.

IN small arms we have to congratulate ourselves upon satisfactory progress in the armament of our troops with the Snider converted rifle. Although but a temporary step, this is one which enables us to keep pace somewhat with the times, and prepares our soldiers for a more perfect weapon. What this weapon is, or will be, the future alone

Digitized by Google

can decide. We have had a grand trial of breech-loaders during the past year, which ended in the selection of nine rifles out of 112 sent in for competition. These nine are now undergoing further trial, and some day we shall know the results. It is by no means certain that any one of the nine will be adopted. If one is accepted, we shall hardly expect to see it adopted in its entirety. We want a light small-bore arm not less than half an inch, and to produce a simple and effective weapon, with a cartridge to correspond, should be work for the year before us to see done. During the past year the Spencer repeating rifle has been improved to meet the views of those who complain that it cannot be used as a breech-loader. By a simple stop the magazine can be shut off, and the rifle loaded at the breech. It thus combines double advantages, and is now a really useful and efficient weapon, and one we should much wish to see introduced as a cavalry arm. By doing this, and by giving the troops an insight into infantry drill, a splendid body of men would be at command. This was done in the American war, and great signal successes were the frequent results. But while we have been working on, perfecting our quick-firing arms, the master mind, whose invention set the whole of Europe on the alert to arm its troops efficiently, has ceased to conceive and execute. Herr von Dreyse, the inventor of the needle gun, has passed away. Among his later inventions, which promise to add fresh lustre to his name, is a grenade rifle, with which some Prussian fusileer regiments are shortly to be armed. The bullet, which is elongated, is filled with a charge of powder, which, on striking, explodes, and scatters the fragments several feet around. The physical and moral effects of this shell upon the enemy are expected to exceed all that has hitherto been achieved in this direction.

GAS ENGINEERING.

NUMEROUS details in gas apparatus have been improved during the past year, and various processes have been modified. Amongst the most recent and most useful introductions, we have to note the ingenious machine made by Messrs. Handyside, of Derby, for drawing and charging gas retorts. The object is to dispense with the laborious duty of charging and drawing gas retorts by manual labour. It consists of an iron carriage running on rails; three iron rakes and three long scoops are carried by frames made to traverse the main carriage in the direction of the retorts. The apparatus is fitted with a pair of vertical high pressure engines, and a boiler by which it is worked. When in operation the scoops are filled with coal through a hopper, and are then propelled to the extremities of the retort, when they are inverted, and the contents deposited in regular order within the retort. The rakes are also introduced in a similar manner, the flaps or rakers being horizontal until required for use, when they are lowered to a vertical position, the rakes being withdrawn and bringing with them the contents of the retorts. The scoops are then introduced with a fresh charge of coal, and the rakes are passed on to another group of retorts. The whole operation of drawing and charging a bench of nine retorts only occupies nine minutes, whilst by the ordinary system about three-quarters of an hour are required. This apparatus has been applied at the Chartered Gas Works with great success; it has also been adopted in Paris. Another practical improvement is Mr. Reid's revolving gas washer, which has been in use at the Leith Gas Works for more than two years. In this apparatus the gas passes through a horizontal instead of a vertical passage while being submitted to a copious shower of water. The principle, which works well, will be found described in detail in the MECHANICS' MAGAZINE for the 20th December last. There yet remain many points open to improvement, and there is a wide field open for the gas engineer in making good his gas holders and pipe joints against leakage. The production of gas is on the increase, and gas engineering becomes daily of greater importance. This may well be so when we reflect that between four and five million tons of coal are annually consumed in the production of gas. Attention therefore should undoubtedly be given to the utilization of other substances than coal for gas-producing purposes, so as to economize our coal supply as much as possible. We know that there are plenty of materials ready to hand for this purpose: they only await careful investigation and experiment to fit them for practical application.

ELECTRO-METALLURGY.

THIS comparatively new art is being gradually perfected, though slowly, as is usually the case with new applications of science to the arts. The year that has just passed cannot be said to have seen many new discoveries in it, but good progress has been made in perfecting old processes. The Paris Exhibition has shown some good specimens both of electro-casting and electro-coating, though we cannot say the best specimens that could have been shown. We think that Messrs. Elkington's warehouse in Birmingham can produce specimens of electro-cast bronzes surpassing anything that was shown in the Paris Exhibition, and also of electro-coating both in silver and gold. In electro-coppering of iron there have been two new processes published, or rather modifications of old processes; these have been noticed in the MECHANICS' MAGAZINE. Dr. Grazer's and M. Bernabe's are the processes here referred to, the former for their coatings only by immersion, and the latter for thin or thick at pleasure by electrolysis; of the latter we hear favourable reports: it is being extensively tested in France, in coating armour plates, and so far with the best results. Last year there was a process patented here for coating iron and steel with silver by Mr. J. Baines Thompson. His process was to coat the article first with a film of iron, by that means getting a pure surface to which the silver would easily adhere; but we understand that within the last six months he has superseded that process, and he now dispenses with the deposition of iron, and for iron substitutes other metals as preparatory coatings that have not before been so electro-deposited. Many difficulties also have been avoided by the improvement in the mechanical appliances. We cannot at present give details on account of space; but we purpose at some future time to give a full account of the processes and apparatus, with their various applications.

It is barely thirty years since the art of electro-metallurgy came into existence, and less than that since the Sheffield close plater described Elkington's then new process of silvering as "no'but a wesh" that "'u'd never do." He challenged the late Mr. Elkington to a test with his "silver wesh" spoons against the Sheffield close plated spoons, which Mr. Elkington readily accepted. Half a dozen of each were put on an iron tray, and subjected to a dull red heat. Of course the Sheffield spoons came out perfectly stripped, but the electro-plate spoons were in no way altered. On seeing this the Yorkshireman exclaimed, "I's bet," and straightway took a licence to work the new process. Since then, a bare quarter of a century, the progress of this art has been truly wonderful. Less than twenty-five years ago electrotyping was little more than an amusement when the most that was attempted was to copy a seal or a plaster medallion. Then the coating of a plaster statue was attempted; but the surface so produced was rough, and the thin coating of copper did not admit of polishing. Lastly, the deposition from within on a mould taken of a statue was accomplished, which produced a surface as fine as that of the statue, and the metal could be deposited of any thickness required.

In France cast-iron statues, fountains, and lamp-posts, have been electro-coppered; these things certainly look very well when coated, but we do not think that the process quite deserves to be classed with electro-metallurgy proper, the copper not being deposited directly on the metal castings, but the castings are first covered with a sort of cement or paint, the surface of which being made to conduct electricity.

These are but a few uses to which electro-metallurgy has been applied. Electro-gilding is extensively practised, and was used for gilding buttons in Birmingham before electro-plating was used, though both were discovered at the same time. Electrolysis is now also used for the reduction of copper ores.

It was proposed long ago by Mr. Weekes to reduce ores by dry electrolysis, but we believe it was never brought into actual practice. At present, we understand that Elkington and Mason have a process by wet electrolysis which they work in their smelting works in Wales, first roasting the ore, then dissolving the calx, and reducing it by a strong current of electricity. In electro-metallurgy we have now in use four branches—electro-gilding, plating, casting, and smelting, or reduction. In plating, there are silvering, coppering, and brassing; in casting, only silver and copper casting; and in smelting, or reduction of ores, only copper. The difficulties of depositing other metals have hitherto precluded their introduction into the arts, but we are year by year progressing, and difficulties are being constantly overcome, and new uses are being found for this art.

CHEMISTRY.

ON looking back over the records of chemistry for the past twelve months we do not find the period distinguished by any of those grand discoveries which have at times set a special mark on a year. No new element has been added to the already sufficiently long list of sixty-four, of which, so far as we know, the material world is made up. One, fluorine, which had probably never before been isolated, has, it is said, been obtained free from all combination; and another, vanadium, which Berzelius was supposed to have isolated, is now said to have been only seen in the form of an oxide. In both these cases, however, it may be said that further investigation is necessary to satisfactorily establish the results published. That fluorine should be a nearly colourless gas, possessing an irritating odour, and having the power of decomposing water and hydrochloric acid, and to appropriate the hydrogen, is in itself highly probable; and, before long, no doubt other chemists will confirm these statements. So likewise we may provisionally accept the statements of Dr. Roscoe as regards vanadium and its compounds, waiting, in the meantime, for the results of other investigators.

But although there is little to be said of advance in our knowledge of the elements themselves, much might be written of the progress made in our knowledge respecting the compounds which these elements are capable of forming. Modern research restricts itself mainly to an investigation of the compounds made up of only four elements—carbon, hydrogen, oxygen, and nitrogen; and too much praise cannot be given to those ingenious chemists who, by adroitly withdrawing an atom or molecule of an element, or a group of atoms from a compound, and introducing a different atom or group, produce new compounds, the number of which is already a source of perplexity to the chemist who wishes to keep pace with the times. On this subject we need not say more, but refer our readers to the researches of Berthelot on the Hydrocarbons, of MM. Caro and Griess on a Series of Bodies in which Hydrogen is replaced by Nitrogen, and of the recent papers of Mr. Perkin on the Artificial

Digitized by Google

Formation of Coumarine, and of Dr. Hofman on Homologues of Prussic Acid, as marking a large advance in our knowledge of what is called organic chemistry.

In applied chemistry it can hardly be said that any strikingly grand discovery has been made. The researches of Mr. Abel on gun cotton have indeed brought that apparently unmanageable body under complete subjection, and we know now all its weaknesses as well as all its strength. It now only remains to determine how the force it is capable of developing can be best utilized for ballistic purposes; and of this also much has been learnt during the past year. The dreadful accident with nitro-glycerine at Newcastle excuses our reminding our readers that a means of rendering that body inexplosive was discovered in the past year. It consists in merely diluting the fluid with wood spirit; and how it came that so able a chemist as the late Mr. Mawson did not resort to this expedient before he attempted to get rid of the store at Newcastle must ever remain a mystery. His fate, however, will serve to impress the fact on any who may in future have the handling of such a dangerous compound.

For any and every technical application of chemistry that has appeared to us of value or interest we may confidently refer our readers to our pages, in which they will find them duly chronicled as soon as made known.

We cannot conclude this notice without a brief reference to the losses chemistry has sustained. First in the list of these must stand the name of the immortal Faraday. Although of late years he has been apt to say with a sigh that he knew nothing of chemistry, the science may fairly claim him for his early devotion to it. The discoveries, however, which constitute his chief fame have been made in another branch of science, to which reference is made in another paragraph; and only a fortunate technical application of benzole, which he discovered, reminds us of Faraday's early researches on coal tar. Dr. Thomas Richardson was better known as a writer on technical chemistry than as a worker in the science. He was, however, a very able practical chemist, and leaves behind a well-earned reputation. In Mr. R. Warington the science has lost another devoted follower, whose name will always be associated with the foundation of the Chemical Society, of which he may be said to have been the projector. Mr. Walter Crum and Mr. Mercer also will be long remembered for various discoveries in connection with the chemical treatment of textile fabrics.

We mentioned just now the general direction of chemical research in these days, one great result of which is the occasional discovery of means of forming artificially bodies which had hitherto been the production of living organisms alone. In this department we may look for still greater discoveries; and whether there be any difference in "vital force" and ordinary "physical force" or not, we do seem to gain daily a deeper and deeper insight into the mysterious operations of nature. It is the special office of chemistry to investigate and unfold these; and with the army of diligent experimenters now devoted to the science we may confidently expect that the year now opening will not close without adding yet grander conquests to the domain of Truth.

PHOTOGRAPHY.

DURING the past year prominent attention has been called to the fact, made known by the Paris Exhibition, that in portraiture English photographers have been in many instances excelled by foreigners. The photographs of M. Salomons, of Paris, created great excitement, his pictures exhibited at Paris and at the recent photographic display in Conduit-street, Regent-street, being superior to those shown by any other competitors. At the photographic societies the merits and demerits of his pictures have been rigidly canvassed. Some of them are not true photographs, but so "touched up," that half their beauties may be washed away by the application of a wet sponge. Others, of great beauty, have not been touched at all, and an examination of the negatives shows that nothing in the finished pictures did not exist in plates from which they were taken. The excellence of these remarkable portraits seems to be due to good lighting, good manipulation, tasteful accessories, and to great care in printing, parts of the negative being partially shaded from the action of light, to increase pictorial effect. The accessories, especially a large piece of velvet which comes out well in the camera, and is judiciously introduced in connection with many of the sitters, are carefully chosen, and the prints, when finished and mounted, are waxed, which increases their brilliancy. Perhaps minute attention to little details of this kind has much to do with the production of the beautiful results. At all events, a standard has been attained, which English photographers have yet to reach. In landscape photography at the exhibition, the English surpassed most nations, and were excelled by none.

The depression in trade, common to all branches of business, has been felt by photographers, and a portion of the decline has been attributed to the knowledge gradually spreading among the general public, that all the ordinary photographs on paper are not permanent. Nevertheless, although carbon pictures by Swan's process are now turned out in great numbers, and are supposed to be as permanent as the writings of the monks of old, who used carbon as the basis of many of their inks, the advantages of pictures so taken seem still to be little known beyond photographic circles. The Government of India recently spent much money in photographing the ancient temples of that empire, since these monuments are fast disappearing under the influences of climate, tropical vegetation, and the destructive agency of man. Little did the projectors of the work know that the records thus taken will probably all fade from view, quicker than the original temples themselves, although, undoubtedly, silver photographs of considerable permanence may be taken by scientific men who carefully conduct all the manipulations upon true chemical principles.

The carbon process has been brought to more perfection during the year. Some little improvement has also been made in processes for reproducing photographic pictures in the printing press by means of gelatine inks, and a new style of picture, called the "cabinet portrait," has to some extent been brought into fashion. With these exceptions, 1867 has witnessed little progress in photography. The principles of the science have, however, undergone rigid examination, and have been brought more into harmony with the discoveries of modern philosophers, in the field of molecular physics. After a photographic plate has been exposed in the camera no change in the collodionized film is visible, neither can the chemist detect any by analysis, yet on applying a developer out comes the picture. The mass of evidence resulting from the discoveries of Mayer, Tyndall, Thomson, Stewart, and others, that the atoms of all solid bodies are in a state of constant motion, has drawn much attention to the theory that the impact of waves of light upon a film of iodide of silver causes a motion of separation between the atom of iodine and the atom of silver, a result which accounts for many photographic phenomena hitherto inexplicable. Another discovery made this year is the true method of producing good films of chloride of silver in collodion, by the wet-plate photographic process. This salt in collodion requires such enormously strong baths and long immersion, that the right way to use it has naturally been long in discovery. The bath should contain one hundred grains of nitrate of silver to the ounce, and the plate must be immersed for about forty minutes to get a good film, suitable for exposure in the camera. A bath containing one hundred and fifty grains to the ounce is still better, and renders a shorter immersion necessary; but whatever the strength of the first bath, the plate must afterwards be placed a short time in a weak one to get covered with solution fit for the application of a developer. These chloride of silver plates are very slow, and in using them much care in cleaning the glass plates is unnecessary. Little else is at present known about them, as their properties are now undergoing investigation. During the year a few new lenses have been introduced, also a little new apparatus, but in photographic appliances there have been few novelties calling for special notice. The pantoscopic camera, a cleverly-designed piece of apparatus, constructed upon highly scientific principles, has not made such progress among photographers as it deserves.

In the coming year attention will probably be directed to the best method of generally supplying the public with permanent pictures. As a kind of forlorn hope, the plan of coating the present pictures with a varnish or transparent film, to protect them to some extent from the action of the atmosphere, has been tried, but excites little confidence, and time only can show the value of these improvements. The most delicate and beautiful pictures producible by photography are transparencies upon glass. These pictures, when carefully taken and cemented between two plates of glass with Canadian balsam, in the same manner that the lenses forming the object-glass of a telescope are united, are believed to be so permanent that they will last for centuries. The fragility of glass is one hindrance to the permanency of these pictures, but the smaller the photograph the less will it be liable to accidental breakage. Many of the public, if they can get great beauty and permanence in small photographs, will not object to extra expense, and it is possible that little gems of transparencies on glass, if introduced, would get a successful reception during the coming year.

METEOROLOGY.

THE history of meteorology during the past year is not without its interest. Notwithstanding the abolition of weather forecasts and of storm warnings, which constituted the immediate practical and useful duties of the Meteorological Office under its late chief, Admiral Fitzroy, the House of Commons voted a sum of £10,500, nearly three times the amount ever before voted in one year, to enable the committee of the Royal Society, under whose direction the office was placed in February, to commence their operations, without making any stipulation as to the resumption of storm warnings. These warnings have now been suspended more than a year; and it seems significant of the impolicy of this retrograde step that the list of wrecks and casualties in the British seas has nearly reached a total of 3,000 for the year just past, a number greatly exceeding that of any previous year. The weather has not been remarkably stormy in these latitudes; and, if the absence of the storm-warnings does not in some measure account for this serious and excessive waste of property and life, we should like to know what does. Shipowners, underwriters, officers, seamen, and fisher men have been clamorous for a renewal of the warnings. The press, eminent scientific men, learned societies, and an influential party in Parliament, have advocated the same measure. Nevertheless, the seafaring community are still without them. They are, however, promised, as has been officially announced by the Board of Trade, but we regret that the new warnings will not be nearly so complete as those previously given. One signal only, that of the "drum," is to be used, which will signify bad weather probable during the next thirty-six hours, for

Digitized by Google

which time the signal is to be kept hoisted unless direction is given for a longer period. Places on the coast, accessible by telegraph, from which requisitions may be made for the warnings, will be supplied with the necessary signal shape and staff without charge, if the community is too poor to pay for them. For an object so decidedly national, because all are interested in the saving of life and property, the Government surely might undertake the entire cost, keeping a vigilant check on the officers responsible for the issue of the warnings, so as to improve the system and confine it to within bounds. Admiral Fitzroy's plan was thus national. In fact, it was at once simple and comprehensive, framed to effect indeed more than was needful, thus providing for greater success. We would have been content had his signals for polar and equatorial gales, the north and south "cones," been readopted. The drum, by which the direction of the coming gale cannot be announced, will thus give foreknowledge of only partial value.

That there are principles truly scientific from which the coming wind can be foreseen not only in strength but in direction also, and, consequently by which weather forecasts may be made, has been demonstrated by Mr. R. Strachan in a valuable investigation lately published. This is not the only scientific contribution to meteorology made during the past year. The Rev. C. Clouston has published a scientific explanation of the weather prognostics common to Scotland. These are hopeful indications of the future advance of meteorology in the direction of practical daily utility. The Meteorological Society of Scotland maintains its characteristic vigour. Not content with the success which has attended its efforts to elucidate the meteorology of Scotland, it is now pushing experiments and investigations abroad, and medical climatology is made an important feature. It has established stations in Palestine, Cyprus, Iceland, Feroe Islands, &c. Its quarterly journal also contains papers of much interest; and we should not omit from our record, that its secretary, Mr. A. Buchan, has this year given to the public a "Handy Book of Meteorology," in the right sense of the word. The British Meteorological Society cannot expect the same measure of praise. Its proceedings lack both in research and in interest. Indeed, we hardly know what it would do but for the labours of its present president, Mr. J. Glaisher, F.R.S., the veteran meteorologist. Mr. Symons, who has identified himself with the subject of rainfall, continues to do good service in rendering his statistics available for the use of hydraulic engineers, and for working out the problem of water supply, which must more and more engage the attention of the public, especially for our largest towns. The vast accumulation of statistics of rain renders the subject appalling. It is a most unpracticable one to investigate with a view to the induction of laws which will serve for future guidance and foresight. Such laws we believe will have to be sought for from very different data to that afforded by the amounts and durations of rain itself; and, at any rate, the Newton for the purpose is not yet apparent.

There can be no doubt that the future has much in store for meteorological progress. Much has yet to be done for the meteorology of the oceans, and of distant semi-civilized and uncivilized countries. This work must be looked for from our Meteorological Office, which we trust the House of Commons will be wise enough to continue to provide for as liberally as it has done this year. We presume the office, at the end of the first year of its new management, will report progress in a straightforward and truthful way.

CONCLUSION.

WE might greatly extend our already lengthy notice by reference to the progress of many other branches of the arts and manufactures. But we have taken those—indeed, we have been obliged to defer our remarks upon electricity and telegraphy until next week—which chiefly interest our readers, and have shown them what has been done, and, to a certain extent, have indicated what remains to be done in the future. One concluding suggestion, however, it occurs to us to offer, and that is, that the question of using petroleum as a fuel for generating steam under marine boilers should be practically solved. We have had several attempts to do this during the past year, but no very great successes. Field's principle, as applied to Cornish boilers, is perfection, and we believe it would prove equally successful if adapted to marine boilers. And this, notwithstanding the circumstance that the Americans have virtually given its application up as a bad job. The Secretary of the American Navy reports that after an elaborate series of experiments, the conclusion arrived at is that the convenience, comfort, health, and safety are against the use of petroleum in steam vessels. All we can say is, that they have not gone the right way to work to use it. Barff's petroleum furnace was recently tried in a small yacht, but under conditions that hindered its successful working. Richardson's petroleum furnace has been extinguished for some time past, and we doubt whether it will ever be relit in its present shape. Looking around us, we see progress slowly but surely going on in every direction, and although it may be retarded and hindered, it never can be stopped. In the year upon which we are now entering, the beauties and mysteries of science will be further developed and unfolded, and their practical application to the wants and requirements of the age further extended. Let us hope for better times, that the high aim of science—usefulness—may be freely developed, and that science itself may be advantageously applied to the practical arts and manufactures, for the advancement of knowledge and the benefit of mankind.

COMPETITIVE GUN CARRIAGE TRIALS.

THE return of the "Minotaur" to Portsmouth from her lengthened cruise offers a favourable opportunity for noticing the experimental trials that have been made on board with gun training gear. That other than the ordinary mechanical appliances for working guns were required to control the movements of modern heavy broadside guns was soon discovered when 6¼ and 12-ton guns were mounted on the broadside, and the question arose as to the best method of applying improved mechanical power for this purpose. Two gentlemen, Mr. Cunningham (of patent topsail fame) and Captain R. Scott, R.N., with the sanction of the Admiralty, entered the lists in friendly rivalry to attain this object, and the plans of both have since been fully and fairly tested. Mr. Cunningham appears to have been the first who went thoroughly into the matter, as 1862 in he carried out a series of experiments on board the gunnery ship "Excellent" with a compressor, in which he introduced the principle of large friction surfaces to check the gun's recoil, in lieu of the the old-fashioned claw and riband arrangement, and this compressor was worked for some time very successfully with the breech-loading 110-pounder Armstrong. In the same year he took out a patent for sundry methods for working heavy guns, including an endless chain for running guns in and out, the chain revolving on the slide and connected with four compressors or nippers on the carriage. Captain Scott, too, soon afterwards brought out a somewhat similar plan. The four 12-ton guns mounted on the main deck of the "Minotaur" may be looked upon as competitive guns during the last cruise of the ship, they have been fitted experimentally with different descriptions of training gear, &c.

The after 12-ton gun on the port side of the deck is fitted with Mr. Cunningham's combined running in and out and traversing gear. The plan is very simple and works the gun most efficiently. Upon the rear end of the slide is fixed a winch furnished with chain and clutch wheels. Upon the traversing bolt on the slide are blocks, with single traversing chains leading through them. When the gun has to be run in the chains are put on the clutch wheels, which being turned round by the winch handle and back and pinion wheels, draws the gun and its carriage up the slide. To change again to traversing gear, the running-in chains are thrown off and the traversing chains put into the clutch wheels. Nothing can apparently exceed the extreme simplicity of this plan, and together with that is the important advantage that it can be fitted on board a ship, thus avoiding the expense and delay of sending the carriage and slide ashore to a factory. This gun was fitted by Mr. Cunningham when the "Minotaur" was lying at Spithead, previous to sailing on her cruise last spring, in less than an hour's time. When Admiral Farragut visited the "Minotaur" at Lisbon, he greatly admired this plan for traversing and running in and out heavy ordnance when mounted on a ship's broadside.

The other 12-ton gun on the port side of the "Minotaur's" deck is also fitted with gear designed by Mr. Cunningham---a detached traversing gear; that is, with the motive power detached and separate from the carriage, a form of traverse held by many experienced gunners to be best of all, as it leaves the gun quite clear. The men in using this gear are kept quite away from the gun, and are, in a great measure, out of harm's way when a shot chances to enter the port. The crew of this gun speak very highly of its traversing gear, and profess to have beaten all the other guns with it in point of time in traversing. Mr. Cunningham fitted this gear to the gun nearly three years since, and it remains now in perfect working order. The running in and out provisions of the gun are on the endless chain principle, as applied by Captain Scott, and are of a very efficient character. The traversing arrangements of the two 12-ton guns on the starboard side of the ship's deck is on Captain Scott's plan, and is markedly different from the plan followed by Mr. Cunningham.

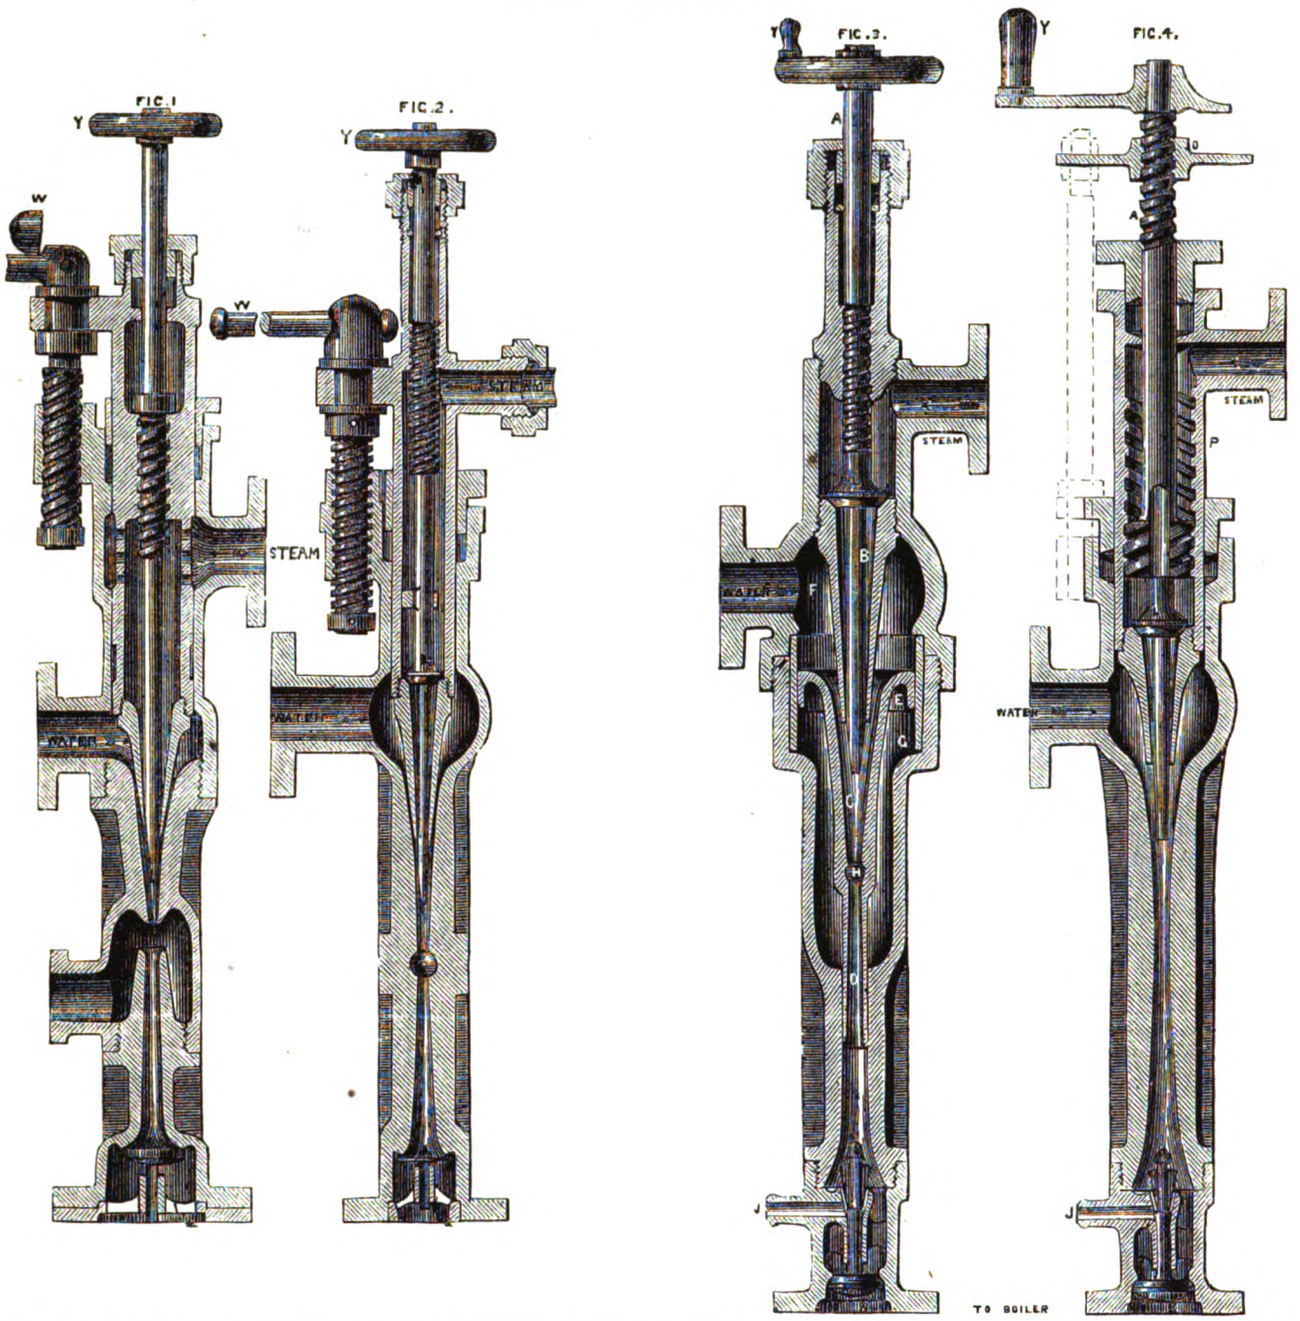
Captain Scott traverses his two guns by means of massive toothed and curved metal castings fixed to the deck, on which a bevil wheel upon a spindle on the slide works. On the foremost of the two guns the crank handle which turns the spindle is at the rear of the slide. With the aftermost gun the crank handle is fixed at the side, the motion being conveyed by an endless screw. Both these guns are run in and out by endless chains fitted on Captain Scott's plan. It will be at once seen that Captain Scott's arrangements for traversing his guns are much more perfect as pieces of machinery than those of Mr. Cunningham. There is, perhaps, a trifle too much of engineering skill bestowed upon them. Mr. Cunningham appears to have based all his arrangements upon simplicity and the use of the smallest possible number of working parts. In this he has been eminently successful. There is nothing in any part of the fittings but what can be applied, changed, or repaired by an ordinary ship's smith or armourer and at once understood by the seaman. In addition to the evident superiority of the Cunningham over the Scott method of traversing and running in and out of the guns in point of simplicity, it has also the advantage in point of cost; the Cunningham gear, it being understood, can be fitted to a gun for £30, whereas the Scott gear would cost between £200, and £300. According to the "Times," from which paper we take the foregoing particulars, the tests to which the gear of all four guns have been submitted on board the "Minotaur" have been of a very severe character, a large number of rounds having been fired from each with heavy service charges, and under all conditions of sea and weather.

SOCIETY OF ENGINEERS.

AT a meeting of the Society of Engineers, held December 16, 1867, W. H. Le Feuvre, Esq., in the chair, the following paper on "The most Recent Improvements on the Injector," by Mr. James Gresham, was read. The growing importance and increased application of the injector, render it unnecessary to apologize for reintroducing the subject before this Society. The complete and admirable paper of Mr. Lewis Olrick, read at a meeting here some two years ago, pointed out with clearness and force the action of the apparatus, and gave a succinct account of the modus operandi of the instrument. The value of Mr. Olrick's paper was considerably enhanced by a series of elaborate and precise mathematical formulæ. The treatment of the injector in this paper will be from an eminently practical point of view, and such knowledge and information as the writer has gained from long and active experience in working the injector, as well as a thorough knowledge of the experiments that have, from time to time, been found necessary for its further improvement, will now be laid before this Society, and the writer may be considered fortunate if, after a description of, and reference to, the models and drawings, he shall have removed a little of the prejudice which is inseparable from a new invention. Since the introduction of the injector into England, it has been the object of those interested in its success to obviate and overcome, step by step, the difficulties that were originally found attendant upon its working, by watching its performance over thousands of miles of railway, under every variety of circumstance, and by careful observance of its working, and numerous

Digitized by Google

SOCIETY OF ENGINEERS.



experiments on stationary as well as locomotive boilers, many improvements have been made, resulting in its present advanced state. The great objection raised by a driver to the use of the injector, when first applied to his engine, after his long use of the pumps, is the number of handles he has to manipulate at starting the injector, all of which must be open and closed in their proper order to secure the efficient working of the instrument; and though the increased labour may at first seem but a trivial objection, those experienced upon the "foot-plate" will admit that it is a valid one, remembering the number of claims already on the driver's attention, which, by the original form of Giffard's injector, is increased by at least four necessary and distinct operations to be performed, as well as a no less important caution to be noted, as will be seen from the "method of working" issued by the makers.

The method of working, as taken from the printed instructions, is as follows:—First, turn the wheel or handle W to the position suited to the steam pressure in the boiler, the higher the pressure of steam requiring the greater opening. Second, open the cock on the steam pipe. Third, turn slightly the wheel or handle V, which will admit a small quantity of steam to the apparatus, until water is seen to issue from the overflow pipe. Fourth, as soon as this happens, continue to turn upwards the wheel or handle V until the overflow ceases, and thus give full liberty to the steam to act upon the water, and drive it into the boiler through the delivery pipe. If, however, after having turned the wheel or handle V to the extent of its range, the overflow still continues, it should be stopped by reducing the quantity of water by the wheel or handle W. The injector is working properly when there is no discharge from the overflow pipe, and no more steam is admitted than is absolutely necessary to pre ent that discharge. N.B.—The jamming down of the wheel or handles V and W should be avoided. The instrument is purposely neither made steam nor water tight, and when stopped the steam and water must both be shut off by the cocks.

This is certainly formidable, and one of the objects sought by the improvement about to be described is to remove the greater part of this manipulation at starting, while at the same time securing a more efficient and durable instrument, with nothing in the constructive detail that can fail, except through actual wear or tear. It has been found that more failures in the working of the injector have been traced to the burning or wearing away of the packing than to all other sources combined; and in the late improvements it has been determined to remove all the internal packing that cannot be reached from the outside. The adjusting of the injector to the various steam pressures has been reduced to one operation, or rather, the adjusting of the exact proportion of water to steam, for the various pressures, hitherto accomplished by two separate and distinct handles, has been arranged to be accomplished by one handle alone.

Fig. 1 in our engraving shows an injector as constructed by the original inventor, M. Giffard, with a separate adjustment for both water ans steam, to which applies the instructions for working previously quoted. It will be apparent that some considerable experience, only to be obtained by practice in the working of the injector, mud be needed before an ordinary fireman would be able to turn the handle W to the position suited to the steam pressure in the boiler, seeing that no further instructions can be given than "the higher the pressure of steam requiring the greater opening." It has been attempted to index these injectors for the various pressures, but without success, as the position of the water regulator not only varies for every different steam pressure, but also varies considerably for the same pressure, owing to the change of temperature of the water supply, and the height it may have to be lifted. It is to be attributed entirely to the amount of manipulation and attention required to adjust the injector to work properly at the different steam pressures, that on boilers with irregular work to perform, and having only small steam and water space, as compared with the heating surface, we see the injector constantly losing hot water at the overflow pipe, or, as some drivers call it, "working sick." This frequently occurs, and is a great objection as well as loss. Another disadvantage in the original form of injectors is the "whip-cord" packing on the ram X.

The objections to this internal packing are fatal, especially when an injector has to lift its supply-water from a considerable depth; for it will be

Digitized by Google

seen, on reference to the drawing, that it is by the fit of the ram in the body of the apparatus, and this packing alone, that the steam is prevented passing direct from the steam-pipe to the water-chamber, where the vacuum is formed to lift the supply-water for starting the injector; and it will be apparent that unless this packing is perfectly steam-tight, no such vacuum can be created. The frequent failures of this injector, when used for stationary boilers, where the supply water has been considerably below the level of the boiler-house, has long ago led to its abandonment, and the adoption of another form of injector, with a fixed partition between the steam and water cones, designed by the writer and Mr. Robinson. The original injector also fails upon locomotives from the same cause producing a different effect—that is, when the packing on the ram gets worn, which is soon the case if the driver only adjusts his injector as often as he should do. The steam passes direct into the water-chamber, and mixes with the supply-water before it enters the combining cone; and supposing the water in the tender to have been heated some 130 deg., say, whilst waiting at the station, the steam leaking past the packing on the ram will soon raise the temperature of the water enough to make the injector uncertain in its working, or stop altogether. Many drivers, finding out this, have given up adjusting their injectors, to save the trouble of frequent packing, and let the ram get fast in its place, preferring the lesser evil, viz., the occasional loss of hot water at the overflow pipe, from non-adjustment to the various pressures, rather than have the uncertainty of the injector working at all when the packing becomes inefficient.

Fig. 2 is intended to show one of the ways in which the difficulty of packing the ram has been overcome with the least possible alteration of the original form of the injector: for, notwithstanding all that has been adduced against this arrangement, a vast number are in use. The dispensing with packing is accomplished after this manner:—In attaching the injector to the boiler, care is taken to have the steam pipe sufficiently long; that it shall have the requisite elasticity to admit of its moving at the end attached to the injector—say in the case of a locomotive 1½in.; this requires the pipe only to move ¾in. up or down from a straight line—and those conversant with the bending of brass and copper pipes, will know that pipes of any considerable length are seldom bent nearer than ¾in. to their required positions when fixed, and that their elasticity readily admits of bringing them home to the desired place. Advantage has been taken of this to attach the steam pipe direct upon the moving ram itself, placing it beyond all possibility for the steam to pass into the injector at any but the right point. Experience has proved that the steam pipes for injectors at present in use on locomotive and other engines, are considerably larger in diameter than is requisite for the efficient working of the apparatus; and several large firms and railway companies are now fitting their injectors with steam pipes in the proportion of ⅛in. to the millimetre, equal to 1in. pipe for a No. 8 injector; in fact, some No. 8 injectors are working at the present time with ¾in. steam pipes, or about 1-5th the area given by M. Giffard. This may seem strange at first, but we may be helped to believe it when a locomotive engine on one of the principal lines can be pointed out in which all the steam for the cylinders was made to pass through a 1in. pipe about 1-20th of the usual area. When the steam pipe is of necessity very short, a coil is made in it, after the manner of Allen's patent tender-pipe coupling. Another improvement claimed for this injector, is the impossibility of steam blowing through it when not at work—a circumstance which happens under the original form of injector at nearly every station where a locomotive engine stands any length of time. This blowing of steam is prevented by the conical valve L on the steam spindle shutting down firmly on its seating at the base of the steam cone, and by the removal of the packing from the ram.

Figs. 3 and 4 show two different methods of reducing the adjustment of the injector to the various conditions under which it may have to start working to one single operation. Fig. 3 represents an injector with the water supply self-regulating, the inventions of Mr. William Sellers, of Philadelphia, U.S., and is certainly the most elegant improvement that has been made upon the injector since it left the hands of the original inventor. The arrangements to enable this apparatus to dispense with internal packing, and to be started by means of one operation, are the invention of the writer. One handle, marked V, regulates the steam supply, any increase or decrease of which will cause a corresponding increase or decrease in the water delivery. This self-regulation of the water supply is obtained by the alternate action of a pressure or vacuum, as the case may be, upon a piston attached to the water or combining cone, and working in a cylinder formed by the body of the injector. Referring to fig. 3, A is the steam regulating spindle, B is the steam cone, C is the water or combining cone, D is the receiving cone, E is the piston attached to the water or combining cone C, and separating the water chamber F from the air-tight chamber G; H is a hole forming a space between the combining cone C, and the receiving cone D, and communicating with the air-tight chamber G; J is a valve for allowing the steam and water to pass into the atmosphere at starting; K is the foot valve to prevent the return of water from the boiler when the injector is not working.

In starting the injector—supposing it to be in communication with both steam and water—it simply requires the spindle A opening, say, a quarter turn, until water is seen to issue through the waste valve J, then to continue opening up the spindle until this valve closes, which will take place immediately the relative proportion between the water and steam has been established. This regulation is obtained by the rising or falling of the piston E, thus increasing or diminishing the annular space between the steam cone B, and the water or combining cone C. Supposing more water is admitted between the annular space than is requisite for the proper formation of the jet, part of the surplus escapes through the hole H into the air-tight chamber G, and raises the piston E, reducing the quantity of water admitted until it is in the right proportion to the volume of steam. The piston will then remain stationary until some change takes place in the pressure of the steam, or pressure of the supply-water. If the pressure of the steam diminishes, more water will be driven into the air-tight chamber, and the piston will continue to rise so long as the pressure of the steam continues to diminish; if, on the contrary, the steam pressure increases, it will require more water to condense it, and the increased velocity of the jet will carry along with it a portion of the water from the air-tight chamber, creating a vacuum therein; then the pressure of the atmosphere on the water in the supply tank will cause the piston to fall, and admit more water around the steam cone, until the exact proportion of steam and water be again established. The action of this injector is shown very clearly by the sectional model.

It will be seen that the lower end of the steam spindle A is made hollow. This arrangement enables the injector to lift its supply water with certainty from depths below that at which it is convenient to place the apparatus itself. By giving the steam spindle a quarter turn, it elevates the conical valve T a short distance from its seat, and the steam is allowed to pass down the centre of the spindle in the requisite volume, and at a high velocity, carrying along with it the air existing in the water chamber G, and cones C and D, passing out into the atmosphere at the waste valve J, creating a much greater vacuum than can be produced by allowing the steam to pass round the end of the spindle, as is the case when the injector commenced to work. There may be a slight disadvantage in using the self-adjuster where the temperature of the supply-water is high, owing to there being no overflow pipe to allow of any surplus water escaping after the jet has been established. This is felt when the supply water has reached a temperature at which it requires more water to condense the steam than can be carried along with the jet into the boiler. Under these circumstances the injector would be difficult to start, and when started liable to stop, owing to the surplus water finding its way into the air-tight chamber, thereby forcing up the piston and shutting off the supply-water altogether. This drawback is overcome by one of the modifications about to be described.

Fig. 4 shows an injector in which the relative proportions of water and steam are regulated, or adjusted, by means of one and the same handle. The double adjustment is accomplished by means of two screws of different pitch upon the steam spindle A, one screw working in a fixed nut O, and the other working in a movable nut cut upon the sliding ram P, thus producing a differential motion, causing the spindle to rise, and the steam cone to fall. The manipulation in starting this injector to work is exactly the same as for starting the "self-adjuster," previously described, viz.: Open the steam spindle A one quarter of a turn, wait until water is seen to flow from the waste valve, then continue to open the steam spindle until this valve closes, which will take place immediately the relative proportions of water to steam have been established. Its action may be thus described:—By giving the spindle the requisite part of a turn, the supply is lifted in precisely the same manner as by the self-adjuster; then, by continuing to turn up the steam spindle, the free volume of steam for working the injector is allowed to pass. At the moment this occurs there will be more supply of water than is required for condensing the steam, the surplus passing out at the water valve J, but the continued upward movement of the spindle causes the steam cone to approach the water cone, reducing the supply water to the extent required to condense the steam. This point is indicated by the instant closing of the waste valve J, showing that the jet is established, and passing into the boiler through the foot-valve K, it being impossible for the waste valve to close until the foot-valve is opened by the passing of the jet into the boiler; therefore it will be seen that these two valves are combined, the action of the one being dependent upon the action of the other.

When the injector is stopped working the positive action of the foot-valve K is secured, by making it act like a piston as well as a valve. This is accomplished by causing it to lift some distance from its seat before there is space for the fluid to pass; then in closing to shut off the passage for the fluid some distance before reaching its seat, the action changing into that of a piston in a cylinder. By this means the requisite amount of power is obtained for lifting the waste valve from its seat, and thereby giving the required opening to the atmosphere for again starting the injector. The area of the waste valve J must not be more than 1·4 times the receiving cone D, otherwise the pressure exerted by the injector would be reduced to such an extent that it would not be able to open the foot valve into the boiler. The advantages claimed for this injector over that of the "self-adjuster" are due to its being able to work with an open overflow or waste pipe. This empowers it to take its supply water some considerable number of degrees hotter than can be taken by the "self-adjuster." Another advantage of the open overflow is the peculiar singing noise made by the jet passing through the atmosphere, telling by the sound when the apparatus is working properly. Many drivers look upon this as a great desideratum. The open overflow arrangement is shown by the sectional model. The conical valve L on the steam spindle is considered a better way for shutting off the steam than allowing the spindle to fit in the apex of the steam cone, and might be applied advantageously to every form of injector, preventing the possibility of bursting the cones by jamming down the spindle. The injectors shown in Figs. 3 and 4 give an increased delivery in gallons per hour of 35 to 40 per cent. over Giffard's original calculations. This is owing undoubtedly to the improved proportions and the entire exclusion of the atmosphere attained by the use of the self-acting valve.

SURGICAL PNEUMATICS.

THE importance of preventing atmospheric air from being in contact with sores and wounds is now generally recognized, and the ingenuity of surgeons is now directed towards contriving means for effecting this desirable end. Dr. Guerin has communicated to the Academy of Medicine the description of an apparatus by means of which pneumatic occlusion, as it is called, may be extended simultaneously to all the patients confined in the same surgical ward. We read in "Galignani" that it consists of a hemispherical balloon provided with three tubulatures; the central one, which is larger than the rest, is fitted with a manometer, consisting of a barometrical tube ending in an india-rubber bag, and filled with mercury. The bag is enclosed in the balloon, so that in proportion to the vacuum effected in the latter, the former is dilated, in consequence of which the mercury in the tube falls, a scale showing the amount of the fall, and hence also the degree of rarefaction in the balloon. The second tubulature receives a tube communicating with the receiver of an air-pump, and by the third a communication is effected between the balloon and each bed by means of india-rubber tubes so arranged that the secretions from the sore or wound of each patient are kept separate for further examination. There are stop-cocks for regulating the degree of vacuum in the central vessel, and the part under treatment in the case of each patient is covered with a sort of india-rubber hood, which effectually protects it in each case from the action of the external air.

APPARATUS FOR BURNING HYDROCARBON OILS.

FIG. 1.

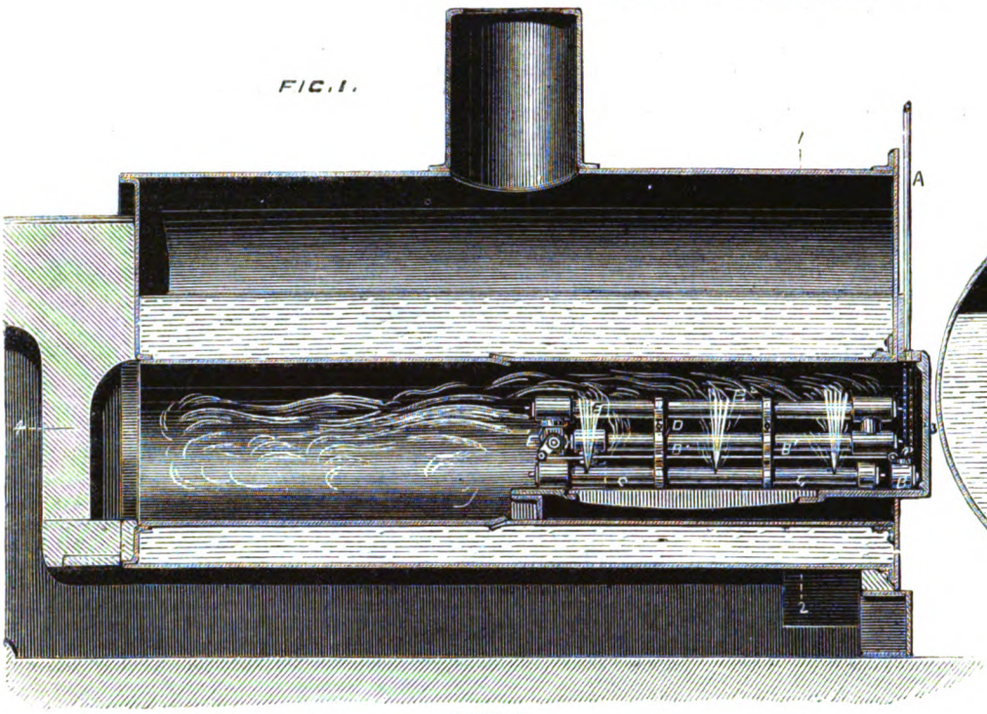

FIG. 2.

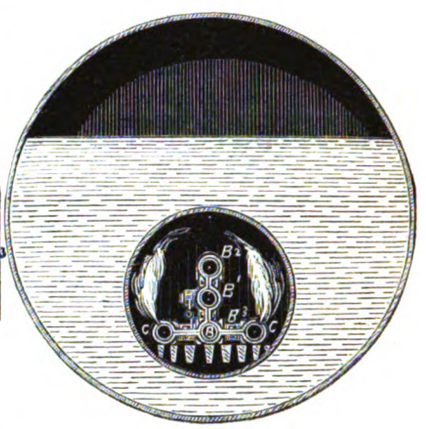

FIG. 3.

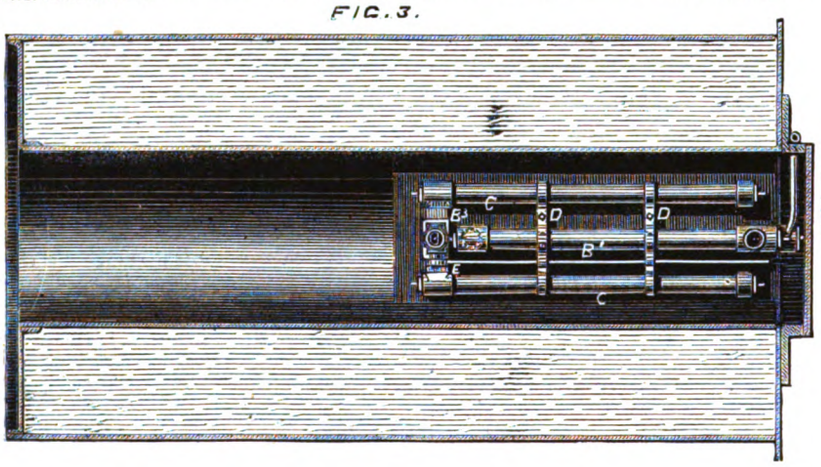

FIG. 4.

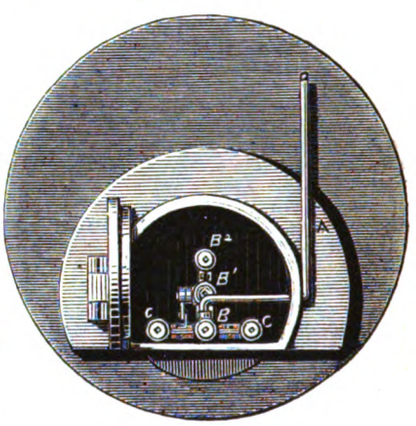

APPARATUS FOR BURNING HYDROCARBON OILS.

THE desirability of using petroleum and kindred oils as a fuel for steam purposes is evidenced by the many attempts to utilize them for that purpose. Amongst the most recent inventions in this direction is that of Mr. Thomas Crow, of West Ham, who has patented an apparatus for economically burning hydrocarbon oils. This apparatus consists of a vaporizer and burner in which a constant but regulated supply of hydrocarbon oil is maintained for the purpose of being converted into vapour and superheated, and in its superheated state consumed at the burner. The form of the apparatus varies according to its application, whether used for heating or lighting, but the principle of construction and action are the same. The supply of oil is continuous, and at a pressure due to the elevation of the oil reservoir. The passages for the escape of the vapour to or its discharge from the burner are so proportioned as to produce a back pressure in the vaporizer, and the heating surface and capacity of the vaporizer and burner are such as to admit of the whole of the vapour generated being superheated before it passes off to be consumed.

In our engraving we have shown the invention as applied to the fireplace of a horizontal cylindrical boiler. Fig. 1 is a longitudinal section taken through the centre of the boiler, and showing the apparatus in side elevation; fig. 2 is a cross section taken in the line 1 2 of fig. 1; fig. 3 is a sectional plan taken in the line 3 4 of fig. 1; and fig. 4 is a front view of the boiler with the fire-door open, showing the apparatus in front elevation. The fire-bars are used to receive the apparatus, which consists of a number of metal pipes coupled together, and so arranged as to require no further support. In this instance, as the fireplace is long and contracted laterally, the apparatus is elongated, and takes a kind of pyramidal form in end elevation, but in a fireplace circular in plan the apparatus takes the form of concentric rings or coils, the flame from the burner being so directed as to heat the pipes forming the vaporizer without impinging upon them, and thereby effect the generation and superheating of the vapour.

A is a pipe leading from an oil reservoir, and used to conduct down a supply of oil to a horizontal pipe B, with one end of which it is connected by a union joint. The opposite end of this pipe B is connected by a union joint with a second pipe B^1, which overlies the pipe B, and in like manner this pipe at its opposite end is connected to a third pipe B^2 placed above it and parallel thereto. From this pipe B^2 depends a junction which connects with a short transverse pipe B^3; this pipe is formed with sockets to receive the ends of two horizontal pipes C C, which are pierced with a row of fine holes, and constitute the gas burner. These pipes are braced together by means of clips D D, which are held fast by bolts and nuts, as shown at figs. 1 and 2, and to facilitate the cleaning of the pipes their ends are fitted with removable plugs. For cutting off the supply of gas to the burner a stop-cock E is provided. The apparatus requires in starting to be heated externally by the application of fuel. The oil is introduced by bringing the apparatus through the opening of a tap in the pipe A into communication with the supply cistern. The oil will then immediately upon its entrance be converted into vapour by the heat. The vapour so formed completes its circulation under pressure through the apparatus. As the vapour thus passes through the apparatus it is brought to a very high temperature, and is converted into permanent gas. The generation of the vapour is continuous, and the escape of the vapour at the entrance for admitting the oil from the supply pipe of the oil vessel is prevented by the pressure of the oil, and the escape of the vapour at its exit openings is partially obstructed by the smallness of the apertures through which it is discharged. An accumulation of vapour is thus kept up within the apparatus, whereby the pressure and the circulation is produced. The gas thus formed passes out from the burners C C, which are so placed in relation to the generator that the flame of the burners will supply the requisite heat to the vapour generating apparatus, while at the same time the heat for raising the required steam pressure will be imparted to the boiler. In order to steady the flame and diminish to any extent desired the intensity of the blast which the pressure imparts to the flame, a perforated disc or plug of iron is fixed in the end of the generator, as at F, fig. 1, which will act as a throttle or pressure check, or the cock E may be used for the same purpose.

This furnace has been used to do the regular work of Mr. Crow's factory, to the exclusion of coals, for the last eight months, and is also in regular use in several other establishments. Some experiments of the evaporating power of tar oil (creosote), made under Mr. Crow's direction, show 18·91lb. of water evaporated for 1lb. of oil burnt. One firm, who have had the furnace in use for the last five months, state that "the cost of the fuel is little more than one-third that of coal." An estimate of quantity, made by this firm, give results:—85 gallons of oil (10·5lb. to the gallon), *i.e.*, 8 cwts. of oil, did the work of 1 ton 2 cwt. 3 qrs. coal. Mr. Goddard, of Ipswich, says, speaking of Mr. Crow's furnace in a recent lecture on "Coal and its Products," "My experience with it shows that one ton of creosote will do the work of three tons of coal, as fuel." We may add that the flame from creosote burned in this apparatus is perfectly smokeless. The oil is difficult to light instantly, extinguishing a lighted match, when dipped into it, even if the temperature of the oil is raised to 140 deg. Fah., or in some qualities to a still higher temperature. The boiling point of the oil is about 500 deg. to 700 deg. The economy is apparent from the fact that the present price of the oil is almost *nil*—say 10s. per ton, when bought in large quantities. Shale oil, petroleum, paraffin, or any other hydrocarbon, would be equally available, but no other oil has yielded the same amount of heat in this furnace, or can be bought at so low a price.

THE NEW RAILWAYS AT BATTERSEA*.

By Mr. C. D. Fox, M. Inst., C.E.

THE system of railways, designed by Sir Charles Fox, M. Inst. C.E., in the year 1862, for the purpose of improving the access to the Victoria Station, by providing additional lines, and avoiding the sharp curves and steep gradients of the then existing railways, comprised:—the widening of the Victoria Station and Pimlico Railway, and of the Victoria-bridge over the Thames; the high level line from the south end of the Victoria-bridge to near Clapham Junction, with a branch to the Wandsworth-road; the diversion and raising of the West End and Crystal Palace, and West London Extension Railways, the Longhedge Junction, and the two low level lines from the Victoria-bridge to Stewart's-lane; and the connecting link between the London and South Western, and the London, Chatham and Dover systems at Clapham Junction. In widening the Victoria Station and Pimlico Railway, the chief work was the removal of the retaining wall from one side of the existing line,—an operation of some difficulty, from the excellent character of the concrete and brickwork originally used, as on account of trains so frequently passing, blasting could not be employed. A girder bridge was successfully substituted in place of an arch over the line, by cutting away a narrow strip of the arch, and inserting one girder at a time.

It was originally intended to construct an independent bridge over the river Thames, to carry three lines of way for the London, Chatham and Dover traffic; but it having been determined to add, at the same time, a third line for the London, Brighton and South Coast Railway Company, it became necessary to make arrangements for joining up the new work with the Victoria-bridge. The new bridge, in common with the original one, consisted of four river spans, of 175ft. each, having arched ribs, with a rise of 17ft. 6in., and of two land openings, carried by plate girders, one of 70ft., the other of 65ft. span. Its width, from the outside of the original bridge to the parapet, was 100ft., giving, with the old work, one structure 132ft. 6in. wide between the parapets. The total length of the piers and abutments just below the springing was 158ft. The excavations of the abutments were got out by means of coffer-dams, the enclosed area being afterwards covered with cement concrete, 3ft. in thickness, then with brickwork in cement, also 3ft. in thickness, surmounted by outside and cross walls of brick in cement, the pockets being filled with lime concrete. In consequence of the proximity of the original bridge, it was impossible to drive the coffer-dams so as to include the whole of the work, and a portion of the face was therefore carried on strong cast-iron girders, put in at low-water mark, resting at one end on the old, and at the other on the new work. By the use of cement, and the care taken to keep the joints thin, the abutments, though bonded up with the old work, had not shown the least sign of movement. The foundations of each pier were carried down by means of four cast-iron cylinders, each 21ft. internal diameter; temporary wrought-iron cylinders, 19ft. in diameter, being used for the top. About 100 tons of kentledge were used in sinking them; this was laid upon stages slung within the cylinders, as being less liable to tilt them than when placed outside, and more easily thrown off when the requisite depth was reached. The cylinders were all sunk to an average depth of 45ft. below Trinity high-water mark, of which 13ft. were into the London clay, the total time occupied in sinking being on an average eight days. The cylinders were filled with cement concrete for a depth of 12ft., and then with brick in cement up to low-water mark. The brickwork was then tested, and afterwards the masonry was commenced. The stonework face, between the cylinders and forming the connection between the old and the new work, was carried on strong cast-iron framework.

The superstructure of each of the river spans was precisely the same, and consisted of eight main ribs, with provision for a ninth. Of these, the rib nearest the existing bridge was only one-half the strength of the others, which were each calculated to carry a single line of way. These arched ribs were of wrought iron, 3ft. 4in. deep, and the flanges were 18in. wide; but for 38ft. in the centre of the span they merged into one with the horizontal girders, thus giving a total depth at the centre of 4ft. 6in. The flanges of the ribs gradually diminished from a thickness of 3in. at the centre to 1½in. at the springing, the webs being of plates three-quarters of an inch thick throughout. The sectional area of the rib at the centre was 166·9 square inches, or deducting rivets, 142·5 square inches; the sectional area of the rib at the springing was 102·4 and 86·5 square inches respectively. The horizontal girder was 4ft. 6in. deep with flanges 18in. wide, and was continuous throughout, the whole bridge being riveted up for a length of 913ft. It was firmly connected with the cast-iron standards at the piers and abutments, in order to obtain the full advantage of continuity for the land spans, and was anchored by a plate running from the top flange down to the cast-iron skew back. The main ribs were braced by transverse girders and by vertical diagonal bracing; the four middle ribs being further cross-braced horizontally.

The calculations of the strains, from which the superstructure was designed, led the author to the conclusion that, whilst cast iron was the best material for arched bridges of single spans, similar bridges of several spans, having piers whose perfect stability under horizontal stress could not be relied on, were, under certain circumstances, exposed to tensile strains which rendered the use of wrought iron most desirable. The bridge was severely tested on several occasions by Major Rich, R.E., on behalf of the Board of Trade. Each rib, where practicable, with the exception of those adjoining the original bridge, was tested with eight of the heaviest locomotives and tenders, weighing 360 tons, or thereabouts, which were allowed to stand on, and also to run over at speed; and the whole structure was then tested with twelve locomotives and tenders, weighing 530 tons or thereabouts. The ribs deflected uniformly, when fully loaded, to the extent of seven-eighths of an inch at the centre; the corresponding ribs in the adjacent spans at the same time showing a rise of one-eighth of an inch at the centre. The girders over the land spans, when fully loaded, showed a deflection in the centre of half an inch. The cross-girders, when a pair of driving wheels rested exactly upon them, showed a deflection in the centre of three-eighths of an inch. The permanent set in each case was scarcely appreciable. Careful observations had been made for nine months as to the effect of changes of temperature upon the structure. This effect was limited to a rise and fall of the crown of the arches, amounting to a maximum of 1½in., and a movement at the free ends of the land arch girders of eleven-sixteenths of an inch. The total cost of the bridge, including the land spans, had been £245,000, which was equal to about £2 13s. per superficial foot of space covered, or about £38 per lineal foot of single line. The bridge was completed in seventeen months; the whole of the ironwork having been supplied and fixed by Messrs. Ormerod and Grierson, the sub-contractors.

The high level line of the London, Brighton, and South Coast Railway Company, with a branch line from the Wandsworth-road, consisted mainly of a viaduct of brickwork, which was described. The bridges were of a heavy character, comprising eighteen spans in wrought iron, ranging from 26ft. to 150ft., three spans in cast iron of from 60ft. to 70ft., and nine spans of brick in cement. The bridge over the London and South Western Railway had a central span of 149ft. and two side spans of 47ft. each, and had two main girders of lattice construction, continuous throughout. The centre-span was erected without the use of scaffolding, by putting together the bottom flange and lifting it into its place, supporting it by temporary truss-rods, and then, erecting the remainder of the girder upon it, inserting the tension bars from either end till they met in the middle. An adjoining bridge, of 120ft. span, was of similar construction. The main girders, weighing 106 tons each, were built on the viaduct, and, when put together complete, were each rolled over into their places during the night, an operation occupying but four hours.

The other lines of this system were afterwards described, and it was stated that these works, which were three years in progress, comprised a length equal to nine miles of double line, of which five miles were on viaduct, and had cost for works only, including the bridge over the Thames, the sum of £910,000. The high level line of the Brighton Company, which was entirely on viaduct, had cost, including permanent way, stations, and signals, and the numerous heavy bridges, £45 per lineal yard of double line. The whole of the works had been executed from the designs and under the superintendence of Sir Charles Fox, M. Inst. C.E., and the author, Mr. Edmund Wragge, being the resident engineer. The contractors were Messrs. Peto, Betts and Crampton, Messrs. Lucas Brothers, and Messrs. W. and J. Pickering, Mr. J. Heywood, jun., executing the ironwork for the Brighton Company.

* Read before the Institution of Civil Engineers.

ARCTIC EXPEDITION.

CAPTAIN SHERARD OSBORN, mourning the present inactivity of the Navy, proposes an expedition of some sort. He thinks that geographical exploration and discovery in the Arctic seas, in Central Africa, in New Guinea, or Western China, in surveying the storm-swept channels of Cape Horn, or exploring the depths and currents of the great ocean, and such like pursuits, are the true school for our naval officers and seamen. The gallant captain, however, is specially in favour of an Arctic Expedition, which he advocates upon the strength of two remarkable feats which have recently been accomplished. It appears that in Baffin's Bay, Captain Richard Wells, of the steamship Arctic, of Dundee, has been further north in his ship in open water than any navigator had previously reached. Captain Osborn thus narrates the circumstances:—"As early as the 20th of June last, the 'Arctic' proceeded up Baffin's Bay, crossed the face of the glacier of Melville Bay, steamed away past Cary Isles and Hakluyt Island, visited Whale Sound of Baffin, and the subsequent scene of Dr. Kane's adventures. Captain Wells then, finding open water to the north, crossed to the west side of Smith's Sound, and still, tempted by a fine open sea, went on till he sighted Kane's Glacier of Humboldt, and must, he says, have then been in the 79th north parallel—considerably north of where I reached in 1850 in the 'Pioneer'—beyond Inglefield in the 'Prince Albert,' and beyond Kane in the 'Advance.' The bold Dundee whaler was still in open water, and adds, 'I should have continued my course northwards had I seen a fish. There was no indication of ice to the northward, the sky blue and watery, and only a few small streams of light ice to be seen.' Of course, Captain Wells did right in not being tempted to risk his owner's property into the unknown straits before him, but I am sure all living Arctic officers will feel with me. Would that one of us, with a well-found discovery ship, could that day have been where the 'Arctic' was, only 660 miles from the Pole, and I fell pretty sure from Kane's report that we know what to expect for at least another 120 miles, or within 540 miles of the axis of the globe."

The other remarkable voyage has been made from the Pacific Ocean by a whaler called the "Nile." She has rediscovered an extensive land, which will be found recorded on all our Admiralty charts since 1850. The Russian Admiral Wrangel first mentioned it in the account of his remarkable survey of the Siberian shores of the Arctic Ocean. The Tchukties now wandering near Cape Chelagskoi aver that a tribe called the Onkillon fled before them across the frozen sea to a land lying north of Siberia, and occasionally seen from Cape Jakan. Wrangel questioned its existence, but Admiral (then Captain) Kellett, in Her Majesty's ship "Herald," in 1850 sighted this land some 30 miles distant, and although he would not name it, as he could not land upon it, he said, as far as eye-sight could be trusted, it was land of a bold character, extending from about 175 deg. to 180 deg. W. long., and in lat. 71 deg. N. It is a verification of this discovery which the whaler "Nile" brings us this year. An American paper states, that the sea within Behring's Straits was so clear of ice this last summer that the "Nile" reached considerably closer to, but it does not appear that any one landed on, Kellett's Land. Her captain traced the land to the 73rd deg. north latitude, and saw it still reaching away to the northward in all the magnificence of snow-capped cliffs and mountain peaks. The gallant captain observes that these two voyages of the "Arctic", and the "Nile" are cheering proofs of the reduced risk attending ice-navigation in steamers instead of the old fashion of whaling with sailing vessels, and he doubts not that we are on the eve of a considerable extension of our geographical knowledge of the North, owing to the keenness of our whale hunters, and the desire of the poor fish to escape from seas ploughed by the keels of our Arctic steamers. Now, we are quite willing to see our Navy legitimately employed, and are ever desirous for the advancement of science. But the employment of the Navy and the advancement of science should have some practically useful end in view, and we are by no means sure that such would be attained by an Arctic Expedition. Suppose we leave the matter to the "keenness of our whale hunters," and allow the reticence of their prey to allure the catchers on to geographical distinction.

RETURN-ACTING SCREW ENGINES OF H.M.S. "DRYAD."

OUR double page illustration with this week's impression shows a pair of return-acting engines of 300-horse power nominal, by Messrs. R. Napier and Sons, of Glasgow, and which were fitted by them in H.M.S. "Dryad." The cylinders, each 62in. in diameter, are steam jacketed around and at both ends. The slide valves are of the equilibrium type, with double ports on each side of the exhaust opening. The packing at the back is the ordinary metallic rings and spiral springs, with outside set screws for adjustment. The expansion valve is the ordinary multiple ported sliding valve. The maximum grade of expansion is 2 from the commencement of the piston's stroke, 6 being the minimum. The side elevation of the engines show the expansion gear, which is the eccentric and slot-lever, the latter being for the alteration of the cut off.

The stroke is 2ft. 6in.; the piston rods, each 5¾in. in diameter, are prolonged to the opposite side of the crank-shaft, the latter being 12⅜in. in diameter. The length of each bearing is 1ft. 10in., and the crank-pin is 12in. long and of the same diameter as the shaft; the cranks are weighted with counterbalances of cast iron, secured by wrought-iron hoops or bands. For greater facility in forging, turning, and fitting, the shaft is flanged at the centre, and secured by bolts and nuts. The piston rods are secured, at the condenser end, into the crosshead by nuts, and the crosshead is placed at the back of the guide block. The connecting rod is 5ft. 6in. in length between centres; the pin is 8in. in diameter, and 12in. long in the block. The lower surface of the latter is 30in. long and 16in. wide, the adjustment being made by the usual slipper and set studs seen in the longitudinal section. The slide-valve motion is on the link principle, with the starting wheel at the side of the main frame, near to which are the steam valve handles, blow through, and injection levers, &c. The brasses in the main bearings for the crank shaft are laterally adjusted by vertical set bolts and nuts.

The condenser is the main feature in these engines, being arranged to suit the particular requirements for the return action of the connecting rod. The tubes, 3,923 in number, are packed in one cluster above and between the guide channels. Each tube is 6ft. 3in. long between plates, the outside diameter being ¾in. and the inside ⅝in. full. The water circulates through three sets of tubes consecutively. The divisional plates are of cast at one end, and wrought-iron boiler plate at the other. The packing is of india-rubber and metal, as patented by Mr. Davidson, on whose principle the condenser was arranged. The air and circulating pumps are situated below the tube compartment, each being 16in. diameter, and receiving motion from the steam pistons. The valves are rectangular, 28in. by 13in. of india-rubber, with gun metal seating and guards. This condenser has an injection valve and stop sliding valves to convert the circulating pump into an air pump when desirable. The injection pipe is 5½in. in diameter, and is placed at the front of the condenser at the side of the main exhaust steam pipe, the diameter of which is 20in., and that of the discharge water pipe 16in.

The feed and bilge pumps, each 3¾in. diameter, are worked from the piston rod crosshead. The snifting valve is 2½in. in diameter, the cylinder relief valve 5⅜in., and the bilge injection pipes 2½in. in diameter, and the blow through valves have each an area of 10·5 square inches to each engine. The screw propeller is a Griffith's, 15ft. diameter, having a mean pitch of 14ft. 6in. The boilers are the ordinary marine tubular, four in, number. Length of tubes in each shell, 6ft. 6in., and the number 272. Length of each firegrate 5ft. 6in. by 3ft. 4in. wide, three in each boiler. The funnel is 3ft. 9in. by 7ft. 9in. The "Dryad" has attained a speed of 13 knots, and her engines indicated 1,600-horse power.

COLOUR OF THE MOON DURING ECLIPSES.*

BY MR. A. BROTHERS, F.R.A.S.

ON the night of October 4, 1865, there was a partial eclipse of the moon, when about one-third of the disc was obscured. My time and attention on this occasion were chiefly directed to some photographic experiments, and it will be remembered I then obtained pictures of the eclipse at short intervals, from the commencement to the end. At about the greatest phase I looked at the moon through the telescope with an eye-piece of low power, for the purpose of noticing whether the eclipsed portion showed colour, and at once saw that the part of the moon most deeply within the shadow was of a decided copper colour, such as I had seen some years previously during a total eclipse of the moon.

The eclipse which occurred on the night of September 13 last was rather more favourable for detecting the presence of colour, as seven-tenths of the moon were covered by the earth's shadow; the weather being clear, many persons have recorded their observations, and as the colour of the moon is one of the chief features of a lunar eclipse, this point attracted considerable attention.

Mr. Browning says, in a letter which appeared in the "Astronomical Register":—"I looked most carefully for colour both with the 10½ silvered glass reflector, furnished with an achromatic eye-piece of very low power, and also with a five-feet refractor; with neither could I detect a trace."

Mr. Slack, who was also observing with a silvered glass reflector, and in the same locality as Mr. Browning, says:—"After twelve, the eclipsed limb grew noticeably redder; the red coppery tint chiefly affected the lower parts of the obscured limb, but was visible further in, gradually blending with the inky tints presented by the umbra at its advancing edge."

Mr. Weston, observing at Landsdown, near Bath, says:—"The prevailing colours were red-bluish and grey, and grey; the redness increased towards the darkened edge of the moon."

Many other observers speak of the presence of colour, but, on the other hand, a few say they did not notice any, the eclipsed portion of the moon merely having a darkened appearance. On this occasion I did not make any photographs, as I could not expect results materially differing from the last, and I gave my whole attention to observing the progress of the eclipse through the telescope, which is a refractor of 5in. aperture. As to the question of the presence of colour, I can most distinctly say that colour gave the moon a very beautiful appearance, and it seemed to me the most interesting feature of the eclipse. The beauty of the moon's surface appeared to increase as the penumbral shadow stole over its surface, and until the shadow itself was considerably advanced, all the details of the lunar surface could be distinctly made out, and during the whole period of the eclipse some of the brighter points of light within the shadow continued visible, as did also the entire disc with many of the details of light and shade. The colour of the eclipsed limb was of a coppery hue, much brighter towards the part most deeply within the shadow. The part of the moon not eclipsed was of a beautiful bluish-grey colour.

That the appearance of colour cannot be caused by the telescope, or by peculiarities in the eyes of the observers, is, I think, proved by the fact, that the same colours are seen whether refractors or reflectors, either of metal or silvered glass, be used; and, as the majority of observers see colour, the eyes of those who remark the absence of it are, perhaps, temporarily afflicted with colour blindness;—the bright light from the uneclipsed portion of the moon may be sufficient to produce this in some persons. If an observer, after looking at the moon through the telescope, attempts to look at objects while the other eye remains closed, it will be found that until the retina has recovered from the excess of light everything will appear misty—in fact, the eye is partially blinded, and it may be that some eyes are sufficiently sensitive to be affected by the diminished lustre of the moon, and may thus be prevented seeing colour, which there can be no doubt the lunar surface presents during an eclipse.

Some observers have remarked on the difficulty of detecting the first appearance of the shadow, and although the exact time is known, the real shadow is not seen until many seconds, or, perhaps, minutes, after the predicted time. In the present instance, I watched very carefully for the first appearance of the shadow, and, having previously ascertained the error of my watch, I took my position at the telescope; at the same time I requested a friend to take particular notice of the time at the moment I saw the shadow. The result thus obtained was within twenty seconds of the time given in the "Nautical Almanac," clearly showing that under favourable conditions, and, if the attention be given carefully to the subject, the real shadow may be detected very near the predicted time.

* Read before the Literary and Philosophical Society.

ROYAL MICROSCOPICAL SOCIETY.

AT the ordinary meeting, held at King's College, December 11, James Glaisher, Esq., F.R.S., president, in the chair, twenty-seven gentlemen were elected fellows of the society. A number of presents in the library were announced, and the following papers were read:—"On the Pedilceliariæ of the Echinidea," by Mr. Charles Stewart; "On a microscopical ferment found in red French wine," by Mr. H. J. Slack; and "On a new species of marine animalculæ," by Mr. Tatham, communicated by Mr. Jabez Hogg. Dr. Maddox exhibited and explained a valuable and interesting collection of photo-micrographs of scales of poduræ and other minute objects, which had been taken with the highest power objectives of various makers, by the Army Medical Department of the United States. A new form of microscope lamp, with parabolic reflector and condenser, designed by Mr. Bocket, and manufactured by Mr. C. Collins, was also shown and described by Mr. H. J. Slack.

BREAK POWER.

IN the fifth series of official reports upon railway accidents recently published, three casualties are recorded which were wholly or partially caused by a want of break power in the trains. One of these accidents happened to the limited mail train on the London and North-Western Railway last July, when the vans and carriages broke from the engine and tender and afterwards came into collision with them, resulting in injuries to both guards and to fourteen passengers. From evidence collected by Colonel Yolland, R.E., inspector to the Board of Trade, it appears that "the ordinary west coast rolling stock was under repair at Wolverton, so that the guards had only single breaks to depend on, instead of continuous breaks connected with the next carriage," and "that it took nearly half a minute to put on one of these breaks." The other accidents referred to took place on the North-Eastern Railway, in one of which a collision occurred between an express train of the Great Northern and a goods train of the North-Eastern Railway Company; and in the other a collision took place between a mail train and an empty coal train between York and Scarborough. The inspector remarks as to the former that "it is a most dangerous practice to despatch heavy express trains without very much more break power than was available in the present instance;" and as to the latter, that "some portion of blame rests with the person who is responsible for the trains being despatched with the amount of break power prescribed by the rule of the company," the rule in this instance having been disregarded.

STATISTICS OF MATCHES.

THE following curious particulars concerning matches occur in a paper lately read to the Société des Ingénieurs-Civils by M. Peligot. It has been calculated that the number of matches consumed in France is about six per head; it is eight in England, and nine in Belgium. Taking the French average as a basis, the number of matches consumed all over Europe in a day is about 2,000 millions, representing upwards of 600lb. of wood. The kinds of wood chiefly employed in manufacturing them, viz., aspen and poplar, are sold by the cubic metre (35 cubic feet); allowing for waste, this quantity does not weigh more than 500lb., so that in Europe alone the number of cubic metres of wood thus burnt amounts to 400,000, being equivalent to 14 millions of cubic feet English measure. To this quantity should be added that of the stearine matches, commonly called vestas, the consumption of which has of late increased very considerably. The weight varies between 3,200 and 4,000 per lb. in France. The quantity of phosphorus used in the manufacture of matches is about 420,000lb., exclusive of chlorate of potash, sulphur, minium, sulphuret of antimony, gum, and glue. There are in Austria manufactories employing 5,000 hands, and the aggregate value of matches produced is 250 million francs. The invention of friction matches only dates from 1832. In 1835, chlorate of potash was partially replaced by minium and peroxide of manganese, and phosphorus by sulphuret of antimony. In 1837 chlorate of potash was completely abandoned for bi-oxide of lead, and then for the nitrate of that metal, and also by nitrate of potash. In France, chlorate of potash continued to be in use till 1847; at present it is only used for vestas. It is a very dangerous substance, since it will explode by mere friction in the mortar.

AGE OF THE HÆMATITE IRON DEPOSITS OF FURNESS.*

By E. W. BINNEY, F.G.S.

THE great value of the vast deposits of hæmatite iron ore found in the carboniferous limestone of North Lancashire, and in a similar position near Whitehaven, in Cumberland, renders any information as to the date of their formation of considerable importance. There is no doubt that the carboniferous limestone was first formed in most instances. Hollows were then made by some agency, whether by aqueous or atmospheric, or both agencies, it is not necessary here to inquire; but most of the cavities bear evidence of some erosive action, their sides being more like old valleys or watercourses than simple fissures. The next question to be considered is when were these hollows filled with the iron ore? No one who has investigated the subject would estimate their age so late as the date of the magnesian limestone, but some eminent geologists have supposed them to have been formed during the lower Permian period, whilst others have adduced reasons for believing that they had been formed during the Carboniferous epoch. There is very little doubt but that large deposits of iron have been met with in both these formations, some of Carboniferous and others of Permian age, but our present enquiry is the geological age of the hæmatite iron ores of Furness.

In two previous memoirs the author has described deposits of hæmatite iron ore, and given his reasons for believing that they had their origin during the Carboniferous epoch, and were deposited in erosions of the mountain limestone in some instances, or in others interstratified in regular beds in the lower coal measures like seams of coal. Long after his papers had been printed, Sir R. I. Murchison, and Professor Harkness, in a memoir on the Permian rocks of the north-west of England, printed in volume XX. of "The Quarterly Journal of the Geological Society," at page 152, says:—"The mode in which that valuable ore of iron hæmatite is found deposited in pre-existing cavities of the carboniferous formation, and sealed up by crab rock (Permian breccia) is a matter of great geological interest. Joints, fissures, and caverns were doubtless formed in the older rocks antecedent to the deposition of the Permian strata, and in these the ores of iron, so widely diffused throughout the Permian rocks, have in this portion of the north-western region assumed the character of hæmatite. This circumstance justifies the inference that these hæmatite ores are the result of an agency which ushered in the Permian epoch. The earlier rocks of both England and Scotland are strongly impregnated with iron, their composition consisting principally of silica and an oxide of this metal. This latter substance originated from the same source which, during the commencement of the deposition of the Penrith sandstones, filled up the fissures in the carboniferous limestone. This conclusion is applicable not only to the Ulverstone district but also to that of Cleator, south-east of Whitehaven, where valuable deposits of hæmatite are also obtained from the cavities and fissures in the carboniferous limestone, which at one time was here covered over by an extension of those Permian breccias and sandstones, now forming an escarpment a short distance west of Cleator Moor. This inference concerning the Permian age of the hæmatite had been arrived at by Professor Phillips, who, in a communication to the British Association, illustrated his opinions by maps and drawings."

The authors of the paper illustrated their views in a section from Park to Furness Abbey, shown in a woodcut, exhibiting two vertical fissures in the limestone rock, filled with hæmatite, and covered up with breccia or crab rock. Now, this undoubtedly shows that the limestone rock was first formed, then that the fissures or erosions were made, and subsequently filled with hæmatite. But at what time the latter process took place, whether during the Carboniferous or Permian epoch, no evidence is adduced by the authors further than that the beds of hæmatite are there covered up by Permian breccia, and some of the latter has been introduced into the fissures. It has been generally supposed by geologists that at the close of the Carboniferous epoch great convulsions took place in the earth's crust, and large quantities of iron were ejected from its interior. Now, the three authors previously named are recognized authorities on the age of hæmatite iron ores, and their opinions deserve great attention. When his papers were written, conclusive evidence could only be given of the age of the hæmatite iron of Ipstones, in Staffordshire, which was clearly interstratified in the Lower Coal Measures between the Rough Rock or Upper Millstone of Professor Phillips, and the Geological Survey, and the Gannister coal. Some years since, Mr. Bolton, of Swarthmoor, near Ulverstone, showed him, amongst other fossils, a beautiful specimen of Sigillaria vascularis, exhibiting both its external characters and internal structure, quite as perfect in every respect as the specimens found in the Gannister or hard coal at Halifax, or the Bullion seam of Burnley, all converted into hæmatite iron. At that time no doubt existed in his mind of its having come from one of the Furness iron mines, but Mr. Bolton could give him no proof of the exact locality where it was found. At a meeting of the Manchester Geological Society, held on May 30, 1866, he gave his opinion of the value of this fossil as indicating the carboniferous age of the hæmatite iron ores of Furness. These specimens have been kindly lent him by Mr. Swainson, of Newland, their present owner, and were exhibited on the table for examination. With them were some other interesting specimens from the cabinet of Miss E. Hodgson, of Ulverstone, a lady well known for her acquaintance with the geology of Furness, and who procured the specimens now exhibited from the Water Blain Mines, west of the Duddon. They do not exhibit their external characters so well as Mr. Swainson's specimens do; but one is a Stigmaria, the root of Sigillaria, and another a Lepidodendron, two common coal plants, which indicate the carboniferous age of the deposit in which they were found as clearly as any fossil organic remains can do. There is no doubt about the locality of Miss Hodgson's specimens. They came from the Water Blain Mines, and plenty more may be obtained from the same place. They are all converted into good hæmatite iron, that substance having metallized them in a similar way, as we find plants in the Coal Measures converted into the carbonate of the protoxide, or the bisulphide of iron, or carbonate of lime.

It was not the author's intention to attempt to give any explanation of the process by which the original ligneous structure of the plant has been removed and replaced by per oxide of iron: that was a subject better fitted for the chemist than the geologist. Now, the discovery of common coal plants not only embedded in but actually formed of hæmatite iron, surely indicates the carboniferous age of the deposits in which they are now found as clearly as it well can be, for the plants must have been floated in with the water which brought the iron, or else they must have fallen into the cavities when such were open at the top, and the iron was in a soft state. Of course, the occurrence of such fossil plants as Sigillaria, Lepidodendron and Calamitis occurring as they do in beds, from the lowest to the highest carboniferous strata, would give little evidence of any particular part of that epoch, but the Sigillaria vascularis, so far as yet known, is confined to the lower coal-field, not far in geological position from the Ipstones hæmatite previously alluded to, and the valuable clay band ironstones now wrought at Hazlehead, west of Penistone. The deposits of hæmatite in Furness and Cumberland, found in hollows of the carboniferous limestone, and covered up by Till, or "Pinel," as it is locally termed, or more rarely by Permian breccia, are so much alike in all their characters, that if the origin and age of one of them are clearly proved, those of the rest must follow almost as a necessary consequence.

* Read before the Literary and Philosophical Society.

ON THE MANUFACTURE OF STEEL FROM CAST IRON, BY THE USE OF NITRATES AND OTHER OXIDIZING SALTS. *

By MR. J. HARGREAVES.

THE object of the invention which I submit to the consideration of the Polytechnic Society, is to effect the acieration of cast iron by a direct process, and thus dispense with the many permutations which it is at present made to undergo before the condition of steel is attained. I effect this by the agency of oxidizing salts and oxides of iron and manganese. The oxidizing salts which are most suitable for the purpose are the nitrates, and especially the nitrate of soda, on account of its lower cost, higher percentage of oxygen, and the highly electro-positive character of its base, which renders it a most effective agent in removing the metalloids, silicium, sulphur, and phosphorus, and the semi-metal arsenic from iron, by forming with them compounds of sodium, thus enabling inferior qualities of cast iron to be used in the manufacture of steel, and also to improve the qualities of malleable iron by depriving it of those objectionable substances. This is effected by placing the converting materials below the fused cast iron, and allowing the products of their decomposition to rise through the fluid metal, exerting while passing through it their chemical energies in separating from the cast iron the excess of carbon above that which is required to constitute steel, and in removing the metalloids which, even in the smallest proportions, deteriorate the value of the product.

The necessary use of fossil coal in Great Britain, in consequence of the scarcity of wood from which charcoal can be obtained, tends, while lowering the cost of production, also to deteriorate the value of the iron produced, by communicating to it some of its own impurities, which, added to those existing in the ore, render the iron very impure. A great proportion of silicium and sulphur are separated by the lime used as a flux in the form of slag. But the last traces of these elements are very difficult to remove under the circumstances; while, with the exception of a slight trace, the whole of the phosphorus originally present in the ore remains in combination with the metal.

En passant, I beg to direct the attention of the chemical members of this Society to a chemical and industrial problem, the solution of which is of great importance to society, viz., the separation of phosphoric acid from the iron ores in such a manner that it may be effected on a large scale, and at a cost sufficiently low to yield a profit upon the phosphoric acid extracted, and yet leave the ores in a suitable condition for obtaining the metal therefrom. The agriculturists of Great Britain have to resort to imported phosphates to restore and maintain the fertility of their lands; and the islands of the Pacific, South America, Australia, and other distant countries are put under contribution to supply them; while beneath our feet and among the minerals which pass through our blast furnaces lie phosphates which, if extracted, would render us independent of those supplies, but which at present depreciate the value of the labour and skill of our iron workers. To know this must give us all a strong sense of our ignorance and weakness, in spite of the repeated and complacent boast of our powers to control the forces of nature. I hope that the attention of chemists will be drawn to this important subject, and that some of us may be able to pronounce the "open sesame" which shall throw open this storehouse of phosphatic treasures.

In 1861 my attention was first seriously attracted to the subject of the acieration of iron by the communications of the researches of MM. Caron and Fremy to the French Academy of Sciences. These communications show that, to form steel with such qualities as will compete with that produced from Swedish and Russian iron, by cementation, it is necessary that the iron should be pure or approximately so; and that to effect cementation, nitrogen must be present in combination with carbon, or in contact with some gaseous compound of carbon. M. Caron disputes the hypothesis that nitrogen is an essential element in steel; but he admits that it acts as an inter-porter or carrier of carbon between the charcoal in the cementing pots and the iron, acting in fact as a kind of chemical shuttle, carrying carbon to the iron, and depositing it within the substance of the metal; and after delivering the carbon to the iron, it returns, and again picks up another charge or load of carbon, which it again delivers to the iron. A very small quantity of nitrogen is by this means made the agent for carrying a comparatively large quantity of carbon; and he proposes cyanide of ammonium as a gaseous cementing agent. M. Fremy, on the contrary, asserts that nitrogen is absolutely essential to acieration, and that in the absence of this element cast iron and not steel is the result of operating upon iron with pure carbon, unless the iron itself contains nitrogen. That iron can be made to combine with nitrogen has been placed beyond doubt by M. Despretz, whom M. Fremy quotes and whose experiments he repeats, a ferrammonium (N. Fe, 4), having in fact been produced; *i.e.*, a compound analagous to the quasi-metal ammonium in which the hydrogen is replaced by iron. M. Fremy proposes to effect the cementation of iron by the use of ammoniacal and hydrocarbon gases, to supply nitrogen and carbon. I was then, and am still, disposed to take the view of M. Fremy as the correct one. But the thought suggested to me by the discussion between these eminent *savants*, was—"Why not obtain and use some material which shall effect the removal of the excess of carbon, with all other objectionable elements, and at the same time add nitrogen, which being chemically very inert, must be in the nascent state to effect its combination

* Read before the Polytechnic Society of Liverpool.

Digitized by Google

with iron, instead of removing the whole of the carbon, and then by a very expensive, laborious, and inconstant process restore a portion of the carbon extracted and a very small portion of nitrogen?"

The great difficulty was to find an agent capable of fulfilling the requisite conditions, which are—1. That it shall remove any desired quantity of carbon, this being varied with the varying proportion of carbon contained in the cast iron, and leave in it just sufficient carbon to effect its acieration. 2. That it shall remove all the silicium, sulphur, and phosphorus, or at least leave only traces of these elements. 3. That it shall supply nitrogen in the nascent state.

I occasionally took up and studied the subject, but with no satisfactory result—as I could not see clearly how to have a practical process, which could compete with those then in operation—till in 1864, when considering the theory of the action of the alkaline nitrates upon the elements composing cast iron, I found that these salts possessed all the properties necessary to accomplish the object I then had in view. 1. The quantity of carbon to be removed could be regulated at will by the quantity of nitrate used. 2. The alkali would in all cases be in excess of the quantity required to form chemical compounds with silicium, sulphur, and phosphorus, and give rise to the formation of silicate of soda, sulphide of sodium, and phosphide of sodium. 3. Nascent nitrogen would be formed in the presence of iron, in consequence of the formation of cyanides, by the reaction of the sodium or potassium and nitrogen of the nitrate upon the carbon in the cast iron, and would also be liberated upon the decomposition of the oxides of nitrogen. 4. The reaction of the nitrate upon fused iron could be easily effected by placing the nitrate at the bottom of a suitable vessel, and allowing the products of its decomposition to rise through the metal.

The writer, after briefly adverting to the great difficulties he encountered in endeavouring to secure some benefit to himself, for the labour he had undergone and the great discovery he had made, and stating that ultimately he had the mortification to find a friend in sole possession of a patent which should have been in their joint names, but which really prevented him from using his own invention, said—I then applied for provisional protection for the use of other nitrates than those of soda and potash, and also for the use of chlorates, manganates, chronates, and stannates. Mr. Robinson, of the Widnes Foundry, giving me facilities in that establishment for conducting the preliminary experiments, I set to work to find some cheaper method of making or obtaining some of the most suitable oxidizing salts, or some more effective method of putting them in operation, so as to economize them. I found that nitrate of iron, and the chlorates of potash and soda, acted with explosive violence, the evolution of oxygen being so rapid that it was extremely dangerous to pour the melted iron upon them. This necessitated the use of some agent which would retard the rapid and violent action of these salts. The first thing that suggested itself was clay, or other inert substance. The use of clay suggested the feasibility of making the whole of the oxidizing materials into a solid hard and dry mass at the bottom of the vessel used as a converter. This again, together with the fact that I had to compete with a lower priced, and in other respects more suitable material, suggested that the clay might be replaced by hæmatite or other oxide of iron, ground into a plastic condition. I should thus get a cheap additional supply of oxygen, and also an increased yield of metal. The advisability of adding manganese to form an alloy with steel, suggested that, where it was desirable, oxide of manganese might replace oxide of iron.

By this succession of thoughts, I got matters into a shape that promised at least a chance of success, and secured these improvements by a second patent, which received provisional protection in May last. Shortly after this I discovered that I was not the first, by many, who had proposed to use nitrates for the purpose of converting iron into steel, and to assist in removing objectionable impurities from it. Neither was I the first to propose placing the salt below the surface of the metal, that the products of its decomposition might rise through and act on it. I also found that the claims advanced by my friend did not exclude me from their use. Under these circumstances my first patent was not worth holding, and I allowed it to terminate, without proceeding to the Great Seal. I therefore congratulate myself on the fact that my invention has been, to some extent, anticipated, and that circumstances impelled me to put the mechanical part of my first crude conceptions into a practical form. The chemical properties of the nitrates and chlorates have frequently been appreciated by other inventors and patentees, but they do not seem to have attempted to get over the difficulty occasioned by their rising too rapidly to the surface of the fused iron, when it is poured upon these salts. Their action has in consequence not been controlled or regulated, but left to chance, and the decomposition of the salt has been so rapid as to render the process a perilous one; and it had to be given up, if for no other reason, because workmen would not willingly imperil their lives and limbs in carrying it into operation, as the explosive violence with which the gases are evolved, often accompanied with showers of incandescent fused metal, thrown about in all directions, involve more dangers than many workmen are willing to encounter.

Before describing the details involved in treating iron by the process for which I obtained the second patent referred to in the foregoing, I beg to point out the general principles upon which it is based. You will have before observed, that to effect the removal of a given quantity of carbon from cast iron, a given quantity of oxygen must be supplied, to convert this carbon into carbonic acid, or carbonic oxide. To convert six parts of carbon into carbonic acid, sixteen parts of oxygen are required, and to form carbonic oxide, eight parts of oxygen combine with six parts of carbon, and in one or both of these forms the carbon is eliminated from the iron. The weight of oxygen contained in the acid of the nitrate of soda, and which will be eliminated from it, is equal to 47 per cent., binoxide of manganese yields about 36¼ per cent., and sesquioxide of iron 30 per cent. It thus becomes tolerably easy to ascertain, especially after a few practical trials, the proportion of oxidizing materials necessary to remove a given quantity of carbon. This is, however, complicated by some conditions, each of which requires a trial or two to obtain exact results. For instance, when the operation is carried on in a deep vessel, the oxidizing materials act more effectively than when a shallow vessel is used, because the products of their decomposition have more time to become saturated with the impurities which it is desirable to remove from the iron. The rate of evolution of the gases from the oxidizing material is regulated by the proportion of oxide of iron or oxide of manganese mixed with the nitrates. The oxides, though themselves evolving oxygen, especially in the presence of carbon, do so tardily; and they restrain the otherwise uncontrollably rapid action of the nitrates alone. By this means the action of the nitrate can be so retarded as to cause only a comparatively slight ebullition.

The nitrate of soda is mixed with a proper proportion of oxide of iron, the most suitable form of which is hæmatite, and when in a slightly moist condition, pressed or tamped into the bottom of a vessel lined with fire brick, the whole is then dried into a solid block. If the vessel has been used immediately before, its heat will be sufficient to dry the mass, but if not heated by a previous operation, it is heated by other suitable means. The nitrate of soda of commerce is generally sufficiently moist, without the addition of more water. When the mass is dry, the fused iron is poured upon it; successive layers being then removed, the materials by their levity are carried through the body of the metal, and the reactions occur, to which I have before referred; and as each layer is removed, the part immediately below is exposed to the heat of the melted metal. A boiling appearance accompanies this action, and a frothy slag containing some oxide of iron, and compounds of soda, with the impurities extracted from the iron, rises to the top. After the action has ceased, in consequence of the converting materials being expended, the steel is tapped out, and made use of in any suitable way. Refined iron, for the manufacture of malleable iron in the puddling furnace, may be made by the use of about 3 per cent. of nitrate and 6 per cent. of peroxide of iron. Steel by 8 to 10 per cent. of nitrate and an equal weight of binoxide of manganese. Malleable iron by 8 per cent. of nitrate and 20 per cent. of peroxide of iron. In each case iron with 5 per cent. of carbon being used.

But it was often suggested to me that the use of separate and special apparatus is objectionable, on account of its expense, as manufacturers are generally averse to any large outlay upon new processes; and that some mode of applying it to the ordinary puddling furnace would be very useful. But there was this difficulty to contend with, the puddling furnace is too hot for the introduction of the converting materials, and fixing them at the bottom, and could this be done they would be decomposed before the fusion of the iron could be commenced, to say nothing of their remaining till it could be melted, so as to allow the gases evolved to rise and act through the fluid metal. I get over this difficulty as follows:—I make the converting materials into blocks or balls, and fix them on the ends of iron rods. These balls being made hard by drying, are ready for use. When the iron is fused in the puddling furnace, and the boil has commenced, one of these balls is pushed to the bottom of the metal in the furnace—the products of its decomposition rise through the metal, causing rapid agitation, which is much more effectual than that produced by the puddler with his tools. After the ebullition has ceased, the rod is withdrawn and another put in its place. The time occupied in puddling is thus very much shortened, the labour very much reduced, fuel saved, and a better yield of metal obtained, in consequence of the soda forming a base which readily combines with the silicic and phosphoric acids eliminated from the iron. In the ordinary puddling operations the silicium and phosphorus are extracted, the previous formation of oxide of iron, with which those acids, which are also products of oxidation, combine. But when silicium and phosphorus are reduced to a somewhat small proportion of the whole, the last traces of them are removed with difficulty, still the powerfully basic character of the soda intensifies the disposition of these substances to separate from the iron, and to enter into combination with itself.

The malleable iron produced from cast iron which has been treated with nitrates is of a very superior quality, having great range of temper. The same metal which by gradual cooling is fit for purposes requiring great toughness and powers of endurance of bending and torsion, may by rapid cooling be made sufficiently hard for wood-cutting tools; and its freedom from impurities is shown by the remarkably thin scale formed when the iron is worked by the smith, and the consequently small amount of loss in working. In this respect it very much resembles the best charcoal iron, and contrasts very remarkably with the iron made from the same "pig," but which has not been previously treated with nitrates. The presence of silicium causes a large amount of waste when malleable iron is exposed to the atmosphere at high temperatures, causing a thick, heavy scale, which must contain at least 70 per cent. of iron.

THE CHASSEPOT-RIFLE.

AN officer of Northern Germany, who visited the camp at Chalons, publishes in the "North German Gazette" the following observations on the Chassepot: "It is now idle to ask if this weapon is superior to the Prussian gun; the question at present is, to what extent that superiority could be injurious to us in case of a war with France. That depends on the precision with which the arm may be used; but the natural vivacity of the French, and their deficiency in the patience which the Germans possess, will be a great obstacle to the acquisition of that perfection. During my stay in the camp I observed that the troops who, with the exception of the Chasseurs, were all armed with the new musket, showed in its use a want of certainty, which is besides easily understood. However, it would be madness to attempt to conceal the superiority of this firearm. In facility of loading the Chassepot is superior to any other system at present known. The number of rounds which can be fired in a minute is—on the Dreyse system, 5; Snider and Joslyn, 6; Milbank, Remington, Richler, and Chabot, 7; and for the Chassepot, 8. The other qualities of this musket are: Its weight is not great (8½lb. the small bore), and, which is more important, the flight of the projectile forms a low trajectory. The latter quality, conjointly with the facility of loading, is especially important in firing by command and at will; in one word, in every case wherh the mass of balls is the essential and where the musket which fires most is the best. The Chassepot is lighter, and its work is much more elegant than that of the needle gun; that is why it is in complete accord with the views of the French soldiers; but it affords less resistance than others to long use in rainy weather."

The officer who wrote the above letter is rather at fault in some of his figures, as the following table of results of firing at the trials of breechloaders at Woolwich last summer show:—

Joslyn	12	shots in 47	seconds.
Martini	12	„ 48	„
Fosbery	12	„ 50	„
Remington	12	„ 50	„
Burton No. 1	12	„ 57	„
Henry	12	„ 57	„
Albini and Braendlin	12	„ 61	„
Burton No. 2	12	„ 62	„
Peabody	12	„ 63	„

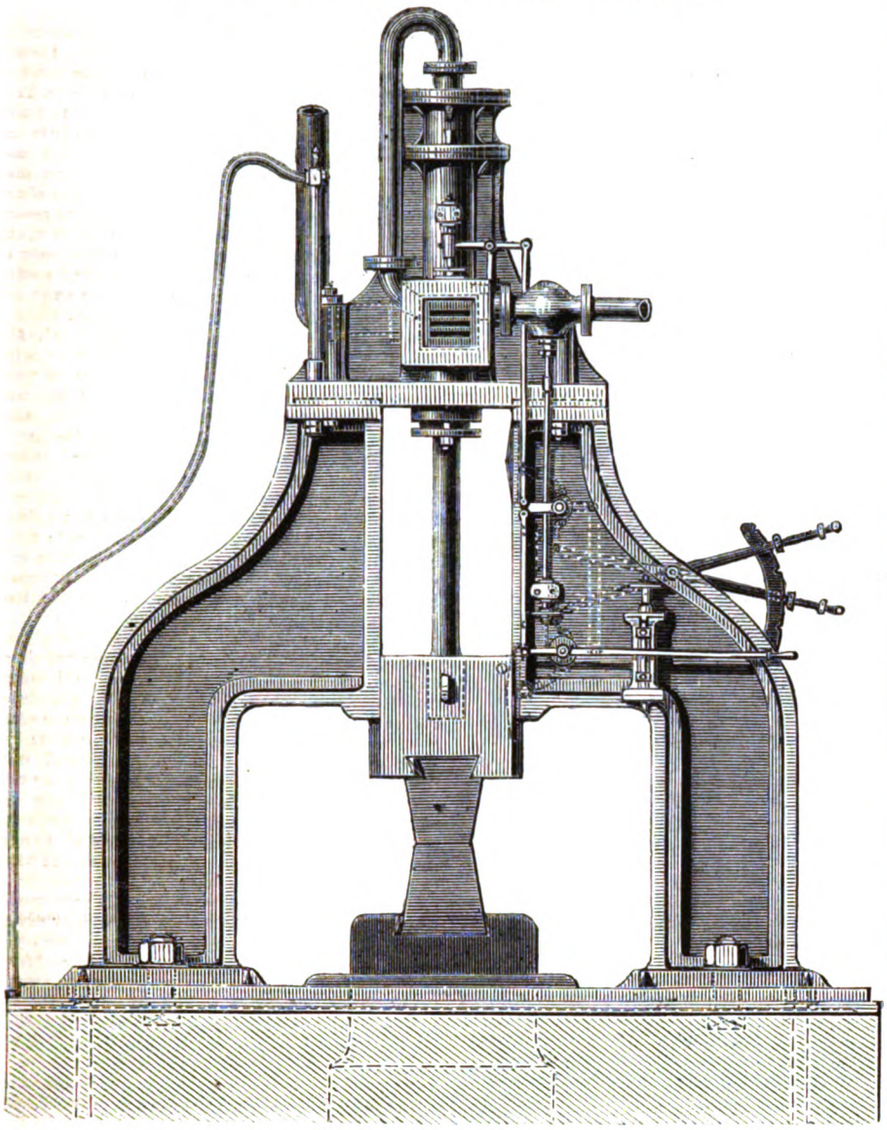
DOUBLE-ACTION SELF-ACTING STEAM HAMMER.



DOUBLE-ACTION SELF-ACTING STEAM HAMMER.

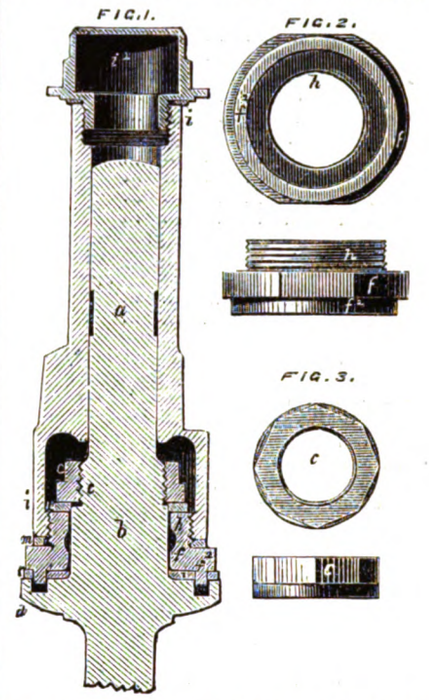
WE illustrate above a neatly finished one-ton steam hammer, exhibited in Paris by Messrs. Vanderelst and Co., a Belgian firm of good standing. The casing shown on top of the cylinder contains a loose piston with a short stud projecting downwards to meet the centre of the working piston at the end of its up-stroke. This "floating piston," as it is called, has its upper surface in constant communication with the steam, and thus serves as a cushion against which the hammer piston strikes when working full stroke. This is an arrangement not uncommon abroad, but can only be considered as a makeshift to save the necessity of good valve gear. The general design of the hammer and the hand and self-acting gear, which are at opposite sides of the frame, will be seen from our engraving. The price quoted for it was £300.

ARTILLERY EXPERIMENTS AT FORTRESS MONROE.

OUR readers doubtless remember the artillery experiments which were carried out by the United States Government about a year since at Fortress Monroe, and particulars of which were published by us. We have now to hand details of another series of experiments much more extensive than the last. In those, plates of wrought iron were fastened in front of a section of a fort, and 12-in. and 15-in. rifled Rodman guns were fired at them. Nearly every shot penetrated, and some went entirely through the protecting plates of iron four inches thick, and only a few shots were fired before the granite wall behind them, varying from 8ft. to 12ft. in thickness, and strengthened with stout iron girders and bolts, became a crumbling ruin. At this point the experiments of 1866 ended, but from the extensive preparations made more definite results are expected from the new experiments, which are probably being carried out at the present time. Sections of three forts, which are fac-similes of casemates of Fortress Monroe and two other works near the mouth of Chesapeake Bay, Fort Carroll, and Wool have been erected. These three works are regarded as the strongest American fortifications, and the same varieties of stone and cement have been used, and their forms exactly imitated. The walls are strengthened with iron bolts and girders, and vary from 7ft. to 12ft. in thickness; the average width and height of the surfaces fronting the guns are about 24ft. each. Plates of wrought iron similar to those used in the last experiments are being placed on these surfaces. Targets for getting the range of the guns, and an electric telegraph for ascertaining the initial velocities of the shots, have been erected. In addition to the casemates, there has been built a heavy cemented stone wall, 2ft. thick and 10ft. high, with sand packed in front for a distance of 18ft., the object being to ascertain the resisting power of this species of fortifications against the same guns and projectiles that are to be fired at the casemates. Three shots from a 15-in. smooth-bore Rodman gun have been fired at this wall. These shots were fired with a solid round shot weighing 640lb., and charges of 100lb. of powder. The gun was 200 yards from the front of the sand bank, and the initial velocities of the three shots varied from 1,500 to 1,600 feet a second. None of the shots penetrated the wall, but they showed a very sensible effect upon it. The first shot put it three-fourths of an inch out of a plumb-line, but did not crack it in the least; the second shot moved it an inch and a quarter further out of plumb; and the third shot an inch further, the three combined causing three inches deviation in the wall, though at the end of the third shot it was still without any crack. A new projectile, called "Taylor's projectile," is to be tried with others in the experiments. This is a compound of steel and chilled cast iron, and its form varies as it is made either with a square, a cup-shaped, or a conical face. It is described as a sub-calibre steel bolt shot encased in an iron jacket, and the advantage claimed is its greater power as a penetrative shot.

WATKINS' CARRIAGE AXLE.

THE annexed engraving illustrates an improved carriage axle, patented by Mr. John Watkins, of Balsall Heath, Worcester. Fig. 1 represents in longitudinal section a portion of a carriage axle constructed according to this invention, figs. 2 and 3 being parts of the same. *a* is the arm of the axle; *b* is the cone or front collar; and *d* is the ordinary or back collar; *c* is a flanged nut screwed internally, this nut being screwed upon the screw *e* made on the arm *a* of the axle. Upon the cone or front collar *b*, and between the flanged nut *c* and back collar *d*, is a revolving collar. This collar is provided with an internal flange f^2 which works in an annular groove *g* in the back collar *d*, as seen in the section fig. 1. The revolving collar *f* has an external screw *h*, upon which the wide open end of the screw box *i* is screwed. The flanged nut and revolving collar have left-handed threads for the left-hand arm of the axle, and right-handed threads for the right-hand arm of the axle. The revolving collar *f* is represented separately in side and front elevation respectively in fig. 2, and the flanged nut *c* is represented separately in side and front elevation in fig. 3. Leather washers *k l* are interposed between the flanged side of the revolving collar *f* and inner side of the back collar *d*, and a leather washer *m* is also interposed between the end of the axle box *i* and the revolving collar *f*. A leather washer *n* is also placed between the flanged nut *c* and outer end of the revolving collar *f*.



In arranging the parts on the arm *a* of the axle, the revolving collar *f* with its washers *k l* is first placed upon the cone or front collar *b* of the axle, its flange f^2 being engaged with the annular groove or channel *g* in the ordinary or back collar *d*. The flanged nut *c* is next screwed upon the screwed part *e* of the arm *a*, and the flange of the nut is made to bear firmly against the revolving collar *f*, the washer *n* being placed between the parts. The revolving collar *f* is thus securely fixed to the arm of the axle, the collar on revolving working or bearing between the flanged nut *c* and the ordinary or back collar *d*, and also working upon the cone or front collar *b*. The axle box *i* is finally screwed upon the screw *h* of the revolving collar, and thereby secured to the collar and to the arm of the axle, the axle box *i* on revolving carrying with it the revolving collar. The outer end of the axle box *i* is closed by an ordinary screw cap i^2. In addition to the flanged nut *c*, a collet or a screw, or lock nut, or a cross pin or cotter may be used to secure the flanged nut in its place.

THE earthquake at St. Thomas has raised the expectations of several other islands as being more suitable stations for the mail packets. Among others, Grenada and Port of Spain have preferred their claims.

ON THE COMPOSITION AND GAS-PRODUCING QUALITY OF TRINIDAD PETROLEUM.

By Dr. Anderson.

I HAVE carefully examined and analysed a sample of bituminous substance, sent to the Laboratory by H. P. Stephenson, Esq., for the purpose of determining its composition and applicability to the improvement of gas obtained from ordinary coal. The substance in question has a brown colour and somewhat bituminous smell. When heated it quickly catches fire, and burns with a smoky flame, leaving a bulky ash. As received it was very moist, and contained 23·65 per cent. of water. It was chiefly found in small hollows, varying from the size of a minute seed to that of a grain of wheat distributed through the mass. When at 202 deg. it was found to contain:—

Carbon	48·66
Hydrogen	6·03
Oxygen	3·59
Sulphur...	3·96
Nitrogen	0·67
Ash...	37·9
	100·00
Coke	49·69
Fixed carbon	12·60

Its composition as imported is:—

Moisture	23·05
Carbon...	37·44
Hydrogen	4·63
Oxygen	2·77
Sulphur...	3·05
Nitrogen	0·52
Ash	28·54
	100·00
Coke	38·24
Fixed carbon	9·70

When distilled at a high temperature for the production of gas, the yield and quality were found to vary with the heat, the quantity being largest when the temperature of the retort was highest, but the quality proportionately diminished.

The two following experiments, in the first of which a red heat was used, and in the second a temperature approaching a white heat, will serve to illustrate this:—

	Red heat.	Higher heat.
Cubic feet of gas per ton	6570	8736
Illuminating power when turned on the standard burner, consuming five cubic feet per hour ...	34 cndls.	26 candles.
Specific gravity	0·65	0·63
Quantity absorbed by bromine		14·7 per cent.
Grains of sulphur in 100 cubic feet of gas	6·58	

For the purpose of testing the effect of this bituminous substance in improving the quality of coal gas, I send a specimen of North Pelton (Newcastle) gas coal, which gives, when distilled alone:—

Cubic feet of gas per ton	10,752
Illuminating power	11 candles.
Specific gravity of gas	0·352
Absorption by bromine	4·07 per cent.
Grains of sulphur per 100 cubic feet of gas	0·704

This coal having been reduced to a coarse powder was mixed with the bituminous matter in the proportion of 4 to 1, and gas was made from the mixture. The results were as follows:—

Cubic feet of gas per ton... ...	10,080
Illuminating power	16·5 candles.
Specific gravity...	0·374
Absorption by bromine	5·66 per cent.
Grains of sulphur per 100 cubic feet of gas	1·43

I have also examined the effect of the bituminous substance on the gas produced from an ordinary Scotch household coal. I used for this purpose Lord Belhaven's Main coal, which was selected because a similar coal had been employed in experiments on Mackenzie's patent for improvement in the manufacture of coal gas. This coal, when distilled alone, gives:—

Cubic feet of gas per ton... ...	10,864
Illuminating power	6·5 candles.
Specific gravity of gas	0·389
Absorption by bromine	3·85 per cent.

Mixtures of this coal in the 20 and 10 per cent. of the bituminous substance were distilled for gas with the following results:—

Mixture containing 20 per cent. of bituminous substance.	Red heat.	Higher heat.	Ditto 10 p. c. Ditto.
Cubic feet of gas per ton.	9072	10,528	10,880
Illuminating power (candles)	14	10·5	7·5
Specific gravity of gas...	0·497	3·43	0·38
Absorption by bromine	6·6	5·3	3·3

In considering these results and the conclusions to be drawn from them, several matters merit attention. 1st. The bituminous substance, as imported, contains 23·05 per cent. of moisture and 28·54 of ash, amounting together to 51·59 per cent., so that less than half its weight consists of matter capable of yielding gas. A good Cannel coal contains about 90 per cent. of gas-producing matter, and gives in round numbers 10,000 cubic feet, having an illuminating power of from 25 to 30 candles. Had the bituminous substance contained no more than 10 per cent. of impurity, it would have yielded on the average upwards 14,600 cubic feet of gas with an illuminating power of 30 candles. It must, therefore, be considered an excellent source of gas; but, in importing it, it is very desirable that the purest and oiliest parts should be selected, so as to avoid as much as possible the expenditure incurred in transporting useless matter. 2nd. The substance contains a large quantity of sulphur, and it is, therefore, important that the best methods of purifying the gas obtained from it should be resorted to. In my experiments on the gas obtained from the bituminous matter used alone, the sulphur was reduced, by careful purification, to 6·586 grains per 100 cubic feet, but I believe that if the purifying apparatus be insufficient, it is probable that it may greatly exceed that quantity. 3rd. When used as a mixture with a Newcastle gas coal, it adds very materially to its illuminating power, raising it from 11 to 16·5 candles. A similar increase is produced in the illuminating power from an ordinary household coal, but in this case the quality of the mixed gas was not sufficiently high to admit of its being used with advantage. 4th. The quality of the gas obtained from the bituminous substance being affected by the temperature of distillation it will probably be found in practice that the best result will be obtained by distilling at a temperature not greatly exceeding a red heat. Looking at the whole of these results, I have no hesitation in saying that this substance may be advantageously employed for the purpose of improving the quality of gas, provided it can be imported at a sufficiently moderate price.

The only difficulty which is likely at any time to arise in the use of this bitumen, depends on the sulphur it contains, and the risk of a quantity of that substance remaining in the gas produced from it. This can only arise, however, from imperfect purification, my experiments having shown that the gas can have the sulphur very effectually removed from it.

I have examined also the quality of this substance in an oil-yielding material, but the results were not such as to encourage me to pursue the investigation into details. It yields, when distilled at the lowest possible temperature, a thick mixed and tarry-looking oil, having exactly the specific gravity of water, from which it cannot be separated in a satisfactory manner. It is well known that the value of oils obtained by distilling bituminous matters depends on their specific gravity being low. I am clearly of opinion that the produce of this substance could not compete with the oils obtained from shale and other similar minerals.

University of Glasgow, 19th November.

We have been favoured with the above interesting report by Mr. H. P. Stephenson, C.E., who enclosed with it the following copy of letter to the Directors of the Trinidad Petroleum Company, for whom the analyses were made, and which embodies the practical conclusions upon the subject:—Gentlemen,—In handing you reports on the gas-producing power of Trinidad bitumen from the Pitch Lake, made at my suggestion by Dr. Letheby and T. M. Keats, Esq., of London, and Dr. Anderson, of Glasgow University, I would draw your attention to the following practical conclusions to be derived therefrom.

1st. As to the high illuminating power of the gas. If the yield per ton of Boghead Cannel be taken at 130,000 feet of 35 standard sperm candles, that of Wigan Cannel at 10,000 feet of 22 candles, and that of Newcastle ordinary coal at 9,300 feet of 13 candles, then a mixture of 20 per cent. of Boghead with 80 per cent. of Newcastle ordinary coal would yield per ton 10,040 feet of 18·7 candle gas, and a mixture of 20 per cent. of Wigan Cannel with 80 per cent. of Newcastle ordinary coal would yield 9,440 feet of 14·9 candle gas. You will observe from the reports before you that with a mixture of the same proportions of Trinidad bitumen and ordinary Newcastle coal, according to Drs. Letheby and Keats, the yield of gas per ton was at the rate of 10,600 feet of 17·6 candle gas, and according to Dr. Anderson it was 10,080 feet of 16·5 candles, the difference between the two being accounted for probably by the use of West Leverson coal in the first instance, and North Pelton coal in the second. It will, therefore, be seen that the bitumen, as a gas-producing agent, is very superior to Wigan Cannel; in fact, to produce the same result, it would be necessary to increase the quantity of Wigan Cannel to nearly 50 per cent. The result also approaches and very nearly equals that obtained from Boghead.

2nd. According to Dr. Anderson's report, the effect produced by a mixture of the bitumen with coal-producing gas of low illumination is very marked. A mixture of 20 per cent. of bitumen with 80 per cent. of Lord Belhaven's Main coal distilled at a red heat, producing 9,072 feet of 14 candle gas, thus rendering useful for the production of gas coal which, carbonized alone, is at present unfit for that purpose.

3rd. As regards the sulphur in the gas, it is to be observed that the purification on a large scale of working will be much more perfect (particularly where scrubbers are used, and the gas is washed with ammoniacal liquor), and it is probable that the quantity found by Dr. Letheby may be considerably reduced.

4th. The price of Boghead being at present about 55s. and Wigan Cannel 27s. per ton in London, looking at the above results the bitumen ought to meet with a ready sale for gas purposes at from 45s. to 50s. per ton, particularly when it is remembered that it may be carbonized with ordinary coal without any deterioration to the coke, and there is no refuse to cart away, as is the case with Boghead. This price would of course be increased if the material could be imported, as suggested by Dr. Anderson, with less moisture than 23·05 per cent.

Under these circumstances I should recommend you to import a carefully selected carp as dry as possible from the Pitch Lake, in order that you may be in a position to supply quantities of from 25 to 50 tons, which will enable any gas company to give the material a good trial on a fair scale, and to satisfy themselves as to the beneficial result to be obtained.—I am, Gentlemen, your obedient servant, (Signed) H. P. Stephenson,

Mem. Inst. Civil Engineer.

15, Abingdon-street, Westminster, Nov. 23.

THE PARIS OBSERVATORY.

THE question of the expediency of removing this important establishment to some more eligible place is now engrossing the attention of the Academy of Sciences. At last week's sitting, M. Yvon-Villarceau read a long paper on the subject, in which he showed that the present building did not even contain decent accommodation for the astronomers who inhabited it, independently of which the murky atmosphere of the capital, and the constant oscillation of the ground, owing to the increasing circulation, rendered all delicate observations impossible. Of these, one of the most difficult is the determination of the exact vertical line, that passing through the zenith and nadir. This is effected by means of a bath of pure mercury, which receives the reflection of the thread required for the purpose. The slightest motion evidently causes the mercury to vibrate but so long as the vibrations are not strong enough to cause the image to get confused, they are not of much importance. It was at first attempted to place the mercury bath on one of the piers supporting the mural circles; but it was soon found that there it oscillated much more than it did on the floor. In order to prevent the vibrations caused by the passing of vehicles, al the streets adjoining the ground belonging to the Observatory were macadamized; but it then became apparent that these vibrations were much less owing to the circulation of vehicles in the immediate vicinity than to that going in the more distant quarters; so that at present it is impossible to observe the nadir before one o'clock after midnight. The noise of the city is another unfavourable circumstance, causing vibrations in the atmosphere, which, coupled with the effects of the gas lamps, render every image so indistinct that the astronomers are precluded from using any magnifying power exceeding 500. Having thus

Digitized by Google

stated the inconveniences resulting from the present situation of the Observatory, M. Yvon-Villarceau proceeds to examine whether the establishment ought to be removed, and concludes by recommending the place now occupied by the windmills at Fontenay-aux-Roses, situated south-west of Paris. The sale of the present ground of the Observatory would produce between four and five millions of francs, which would be quite sufficient to defray all the expenses, and even leave a surplus.

RAILWAY CARRIAGE LOCK.

THIS lock is intended for the better protection and quicker facility of fastening doors; and more particulary carriage doors, and prevents any wear and dithering so often met with in the locks now in use. In our engraving, fig. 1 is a front view, fig. 2 a side elevation, and fig. 3 a plan of this lock. The tongue 1 is kept in its position by the spring 2 after entering the slot 3 in the striking plate 6, the catch 4 keeping the tongue in its place by the spring 5. In the event of either of the springs 2 and 5 breaking, or even

FIG. 1.

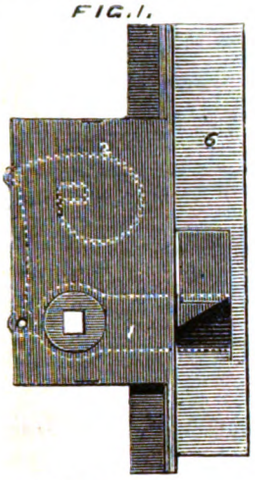

FIG. 2.

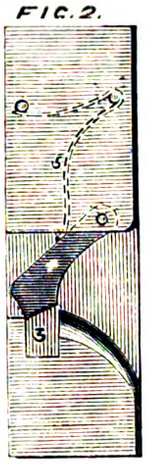

FIG. 3.

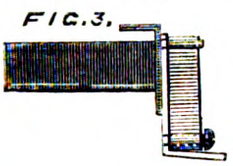

both becoming damaged, the door will be secured by the tongue being kept in the slot. The lock latch has this advantage over the present carriage door locks—the person inside can fasten the door by pulling it to, without the trouble or danger of putting his hand outside to turn the handle. It is also more durable than the locks now in use, having the tongue kept fast by the catch, so that there is no friction on the striking plate nor on the tongue. This lock is the invention of Mr. S. J. Campling, carriage foreman, of the Great Northern Railway (King's-cross Station), on which line the lock is being successfully used.

RAMSBOTTOM AND PEARCE'S IMPROVED TURBINES.

MR. JOHN RAMSBOTTOM, of Leeds, the well-known hydraulic engineer, has lately patented, in conjunction with Mr. T. M. Pearce, of Bradford, some improvements in turbines. These improvements comprise two arrangements, one intended to work water-tight and under the influence of pressure, and the other as an improved turbine or turbine meter working by the velocity of flow. The water engine is best adapted for pressures of 100ft. upwards, and the other for pressures from 100ft. downwards, the object being to adapt the machinery to he circumstances so as to enable the use of water te t more widely extended with advantage for purposes of motive power. The distinguishing character of this turbine consists in the more complete manner in which the principle of opposite action and reaction are obtained, so that the yield of mechanical effect will be the greatest obtainable from velocity of flow.

The inventors construct a circular vessel, inside which they place a hollow girdle with slotted apertures or jets tapering towards its inner circumference; into the cavity of this girdle the water first passes from the supply pipe, and is intended by means of the jets or slots to dispose the fluid to strike upon

RAMSBOTTOM AND PEARCE'S IMPROVED TURBINES.

FIG. 1.

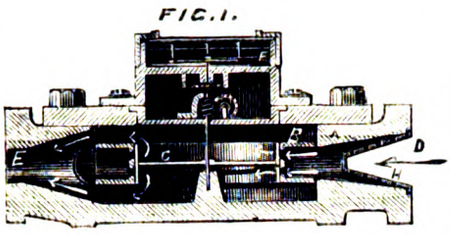

FIG. 2.

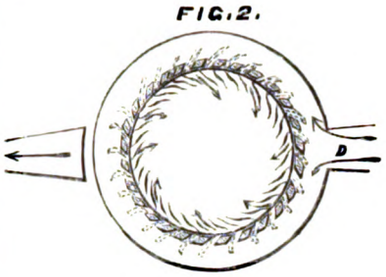

FIG. 3.

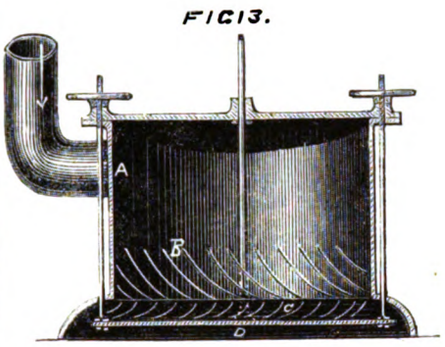

FIG. 4.

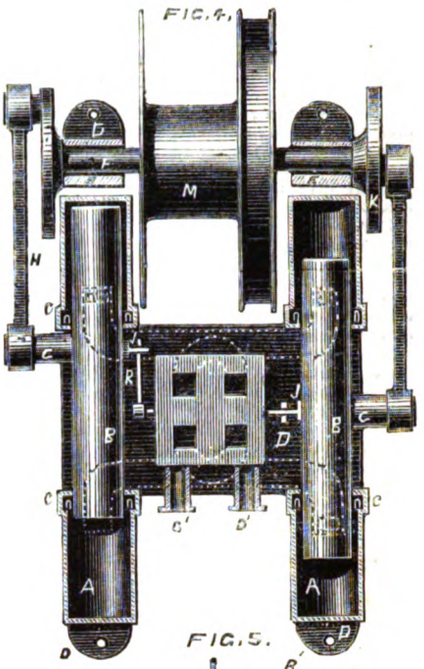

FIG. 5.

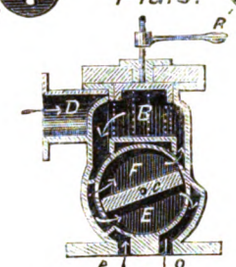

FIG. 6.

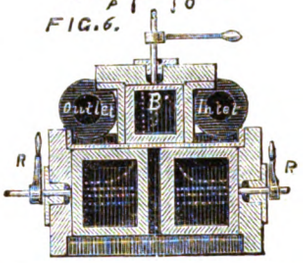

FIG. 7.

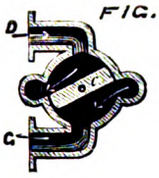

FIG. 8.

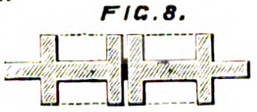


vanes constructed near to the periphery of a wheel arranged to work within the girdle without being in contact with the same. The vanes of this wheel or turbine are of such a form, relatively to that of the jets of the girdle, that the fluid in issuing therefrom upon these vanes shall be diverted in a direction almost directly backwards, and by the forces of action and reaction operative in the fluid, the wheel is thus caused to be driven round on its shaft with greater effect than if less diversion of the current were obtained.

In our engraving, fig. 1 is a vertical section of the turbine as applied mainly for measuring water, showing the inlet orifice D and the outlet orifice E. The casing A is circular and turned out to receive the girdle B, which is also turned on its inner circumference to receive the turbine wheel C, the shaft of which passes upwards to work the indicating mechanism in the box or case situated on the cover of the meter. Fig. 2 is a diagram of the girdle jets and turbine vanes, showing the direction and manner in which the water operates in passing through the instrument. The indicating apparatus is of the usual construction, the fluid enters the turbine in the direction of the arrow D, and passing first through the dirt protector H, and then through the taper jets or slots shown by dotted lines, impinges on the vanes affixed to the turbine disc, giving motion thereto as well as to the shaft and recording apparatus of the meter. The water enters the interior of the turbine wheel on both sides of the disc (as shown by the arrows) and escapes by two orifices leading to the outlet E; this property is important, as it tends to preserve an equilibrium of pressure on the turbine, thus enabling it to perform its duty with greater sensitiveness and freedom from friction.

Fig. 3 is a turbine arranged exclusively for purposes of motive power, and more particularly for low falls or pressures. The novelty here is in the arrangement rather than in the form of this turbine, and more especially in the construction and application of the regulating disc D, which is placed beneath the instrument and arranged to be raised or lowered by rods connected therewith and proceeding to the upper framing of the turbine case, and therg worked or adjusted by screws and wheels actuated either by hand or by an ordinary governor. The outlet or discharge is restricted when this disc is brought nearer to the outlet vanes of the turbine, and its reactive direction is also improved thereby. The object of the regulating disc is to restrict the quantity of water flowing from the turbine when the supply falls short of its maximum amount, instead of restricting the quantity leading to the turbine, as is usually done. And this method of diminishing the outlet orifices utilizes more thoroughly the full effective pressure with varying quantities of water, as well as regulates the speed of the turbine. The fluid enters the casing A and is caused to take a circular direction by the guide vanes B previous to impinging on the turbine vanes C, from whence it issues in an horizontal direction across the edges of the disc D and outwards.

In constructing the hydraulic engine to be worked by pressure, four cylinders are cast on a bed-plate, two at each end, parallel with each other, and in a line with the two opposite cylinders. In each pair of cylinders a ram is placed of sufficient length to extend from one cylinder to the other so as to work within these cylinders. These rams are made water-tight by means of packing rings placed in recesses near to the cylinder covers, and on the rams betwixt these covers are fixed stud pins, to which connecting rods are attached, to give motion to a pair of cranks on a shaft at the extremity of the bed-plate, as well as to work the valvular apparatus. The cranks are constructed at right angles to each other, and the valve box is placed in the middle of the bed-plate betwixt the four cylinders. This valve box is cylindrical, and contains two valves worked from each end of the box by rocking levers driven from projections fixed on the rams. In this valve box at each end are four passages, these passages lead downwards through four corresponding holes in the bed plate, and communicate with each end of the four cylinders respectively

Digitized by Google

The valves are somewhat similar in appearance to an ordinary plug tap, being cylindrical, with a divisional midfeather to separate the feed from the exit side. Fig. 4 is a plan of the engine showing the four cylinders A with rams B contained therein. The glands C contain cupped leathers or the usual hydraulic rings to form the water-tight connexion at those points. The bed-plate D extends lengthwise beneath the cylinders to the journals E, carrying the shaft in one direction, and in the other to the opposite extremity of the cylinders. G, are the stud pins; H, the connecting rods; K, the cranks, and H, the rocking lever for the valves. M is a view of a winding drum and break pulley, as used for colliery and other purposes.

In the centre of the bed-plate is shown a square surface containing four orifices; upon this surface the valve box is fixed, and it will be seen from the dotted lines that the passages leading to the respective cylinders cross each other, causing the valves situate at one side of the valve box to communicate only with the cylinders situate on the opposite side; two of these cross passages being constructed on the upper surface of the bed-plate leading to the rams, and the other two cross passages being constructed beneath the same so as not to intersect each other. By these means the ram which is for the time being passing its centres has its valve worked by the opposite ram, which at this time is in full effect. D and G are the inlet and outlet passages to the valve box. For the purpose of a winding engine and for various other uses it is very important that the motion should be readily reversed; and this engine as constructed admits of the accomplishment of this object, without the link motion or other eccentric valve gear as usually applied by an additional reversing valve which is arranged to change the direction of the fluid leading to and from the working valves or those immediately communicating with the rams by means of a reversing lever to be worked by the attendant.

Fig. 5 shows an end section of the valve box; figs. 6 and 7 are views of the valvular arrangement. B, a longitudinal section of the reversing valve; C, an end section of one of the working valves, of which fig. 8 shows a transverse section. On the supply of water through the inlet pipe D (figs. 5, 6, and 7), it passes through the reversing valve in the direction of the arrows downwards, and through the chamber E; fig. 5 of the working valve to the port O leading to the cylinders and giving motion to the rams communicating therewith, the fluid leaving the opposite ends of which returns through P upwards and across the chamber F and thence through the reversing valve to the outlet pipe G. The reversing and working valves are similar in construction, and it will be seen that if a rocking motion be imparted to them, by bringing the midfeather C of these valves over the opposite portways, it will change the direction of the fluid thereby from one end of the rams to the other end, or from one side of the working valve to the other side thereof, as the motion is changed in either the reversing or the working valve to effect these objects.

SOUTH KENSINGTON MUSEUM.

IN addition to the attractions offered to visitors during the Christmas holidays by the collections at the South Kensington Museum, the Committee of Council on Education have, says the "Society of Arts' Journal," pushed forward the arrangements for the exhibition of the purchases made at the Paris Exhibition, which have recently arrived in England. These latter, as well as some valuable loans, have been temporarily placed in glass cases, and opportunities during the holidays will be thus afforded to the public to view these treasures. The loans acquired from the gallery of the "Histoire du Travail" at the Paris Exhibition, although not numerous, are of a highly interesting character, not only from their being extremely curious and rare as works of art, but chiefly from the fact that they are the property of foreign governments. A most admirable system of international intercourse with foreign powers in relation to works of art may be thus said to have commenced. In the Loan Court are to be found the Crystals lent by the Austrian Government. They consist of five pieces; one piece, standing about 3ft. high, is handsomely carved, and for size is the most important. The enamelled gold work which surmounts the crystal is a delicate piece of execution; and the vase with two handles, richly cut, is a marvel of skilful and dexterous workmanship. Without the evidence of the presence of this vase it would be hard to conceive that any workman could have, out of a simple rock crystal, produced so charming a result. In the case next to the crystals are shown curious specimens of very ancient gold work, discovered at Petrossa, in 1837, and lent to the museum by the Roumanian Government. The date assigned to their origin is about 450 A.D. The work is considered as probably that of Gothic tribes, and the style of the design is called Byzantine. The shapes of the objects, the setting of the stones, and the remarkable pierced work, should be carefully inspected. The largest piece is a salver, about 2ft. 3in. in diameter, with a somewhat rudely stamped ornament round the circumference. A patera is in a good state of conservation, and is, apparently, a capital illustration of the style of art employed at that period for gold work. Adjoining the Loan Court is a portion of the museum assigned to purchases, and here, under glass cases, at the north end of the court, may be found the purchases made from the Paris Exhibition. Of the principal purchase, exquisitely carved and inlaid with precious stones, the spinette by Anniballi de Roxis, Milan, 1577, standing by itself. As a work of art it is unrivalled in the museum. Next to it, but of a totally different genre and date, is the famous inlaid and sculptured wooden cabinet by M Fourdinois, which elicited so much admiration from visitors to the Paris Exhibition. The Italian peasant jewellery, bought from Signor Castellani (through whose means the spinette referred to was likewise acquired), occupies four cases, and has much interest forour jewellers, who would do well to adopt many of the elegant designs to be found in this collection. There is a small assemblage of musical instruments of foreign countries. This, however, is but a part of what was purchased at Paris. The instruments from Japan and China are very eccentric. Beyond this case are specimens of Turkish popular jewellery, and a Norwegian marriage crown. The form of the Danish silver parcel-gilt drinking-vessel is curious, but seems awkward. It is of modern execution but of ancient design. The artistic fans, from the atelier of M. Alexandre, are well represented by eight elegant examples, of which the more noticeable ones are by Messrs. Alexandre, Froment, Frossoy, and Regina. Opposite the inlaid cabinets from Copenhagen stands a very fine vase, of French manufacture, in modern enamelled earthenware, of Persian design, by M. Collinot. The style of this piece of pottery is excellent. A collection, comprising chiefly modern French porcelain, German glass, Austrian ormolu, and French bronzes, complete the artistic purchases from the Paris Exhibition. In the north great court some very accurately working models of mechanical contrivances, cog-wheels, pistons, &c., &c., by Von Schröeder, of Darmstadt, are exhibited temporarily.

Correspondence.

THE SQUARE OF THE CIRCLE, AND "THE GREAT PYRAMID OF GIZEH."

LETTER VII.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—It is only necessary for me to say in reply to the letter of your correspondent, Mr. Wm. Hayden, in your issue of 6th current, that if he will persevere he can divide geometrically, and put together mechanically, the four spandrils, or right-angled triangles E, and the square F I G H in diagrams 7 in my letter No. III. in your columns of October 18th last, as two squares each exactly equal to F I G H. When he has accomplished this, if he then doubts the conclusiveness of the truth that the square contents of a circle is 4-5ths of its tangent square, I shall be glad to hear his reasons.

To resume the thread of my letter No. VI., on the subjects which head this letter, I will now give the measurements and angles from Colonel Howard Vyse's work on the "Pyramids of Egypt," which bear reference to and contain indubitable proof of the geometrical and astronomical objects of the origin and structure of the oldest type of them all, the Great Pyramid at Gizeh of Suphis I.

This Pyramid has four sides facing directly the true four cardinal points of North, South, East, and West. Each side at the base of the Pyramid, including the casing stones, had a length of 764 British feet from corner to corner. Two of the casing stones which originally covered with a smooth polished surface the whole four exterior faces of the Pyramid from a pointed apex at the summit of the Pyramid to the base of each of the four faces fronting the four cardinal points as already stated, were on May 12th, 1837, discovered *in situ* by Colonel Howard Vyse. His journal runs as follows:—(Vol. I. page 261.) "After having gone round the several works, I was sent for about two o'clock to the great Pyramid, as the casing stones at the base had been discovered. The size and angle of the building could therefore be exactly determined, and all doubts were removed respecting a revetment. Two of the blocks were in their original position, nearly in the centre of the Pyramid. Their dimensions were taken by Mr. Brattel, and the angle was 51 deg. 50min. They were quite perfect, and had been hewed into the required angle before they were built in, and had then been polished down to one uniform surface; the joints were scarcely perceptible, and not wider than the thickness of silver paper; and such is the tenacity of the cement with which they are held together, that a fragment of one that has been destroyed remained firmly fixed in its original alignment, notwithstanding the lapse of time, and the violence to which it had been exposed. The pavement beyond the line of the building was well laid, and beautifully finished; but beneath the edifice it was worked with even greater exactness, and to the most perfect level, in order probably to obtain a lasting foundation for the magnificent structure to be built upon it. I consider that the workmanship displayed in the king's chamber in this pavement, and in the casing stones, is perfectly unrivalled; and there is no reason to doubt that the whole exterior of this vast structure was covered with the same excellent masonry."

I have made this rather long quotation, to bring distinctly before the minds of your readers the great and unaltered accuracy of the work in the Pyramid, and the careful description of its exact position by Colonel Vyse. The next measurement given by Colonel Vyse is the perpendicular height of the Pyramid by the combined elements of a square base of 764ft. on each side, and the casing stones of an angle with the horizon of 51 deg. 50 min. This height he gives as distinctly as possible as 480ft. 9in. I need scarcely tell your readers that with such elements of base and angle, the height of the Pyramid was and could be nothing else than 480ft. 9in. At all events, let them project these measurements in 30ths of an inch on elephant drawing paper, and they will soon satisfy themselves.

It is not easy to understand, under the stated circumstances, that the three gentlemen, Messrs. Taylor, Smyth, and James, whom I referred to in my last, should err so egregiously—if it be error—as they do. Mr. Taylor writes as follows:—(Page 19, paragraph 17.) "The angle of the casing stones being 51 deg. 50 min., and the base 764ft., would give for the perpendicular height, supposing the Pyramid ended in a point 486ft.;" and this, after having in the previous paragraph quoted Colonel Howard Vyse's height as 480½ft. What do your readers suppose this wresting of hard fact is for? We have it in paragraph 20, page 22, as follows:—"And this proportion, if our theory be true, would be half that of the diameter of a circle to its circumference, which is stated in the table of constants to be that of 1 to 3.1415927. We may reasonably expect that the Great Pyramid, in its actual measure, as it is now here recorded, would exhibit some approach to this proportion." So far Mr. Taylor. Now for Mr. Smyth. In page 322, Vol. II., under the guise of fair dealing and candour, he writes as follows of Colonel Howard Vyse and Mr. Perring:—"We have, indeed, been obliged to point out in more than one instance, such as that of the height of the present Pyramid, that their numbers are by no means always so correct as they might be;" and in page 323, Vol. II., Mr. Smyth absolutely gives as Colonel Howard Vyse's measurement of the angle of the casing stones, what is not in all Colonel Howard Vyse's work, viz., "angle of casing stones 51 deg. 52 min. × ∞ seconds."

Next, Colonel James, in the "Athenæum" of November 16, 1867, page 650, writes as follows:—"I find that a pyramid having a square base, and a rise at the four corners of 9 parts in 10, has the exact proportions of the Great Pyramid. The side of the square being 764ft., the diagonal is 1,080ft., the half of which is 540ft., from which, deducting 1-10th = 54, we have 486ft. for the height of the Great Pyramid; and this is the exact height given by Vyse. In the Great Pyramid these dimensions are 486 × 2 × 3.1416 = 3053.6ft. 4 × 764 = 3056ft."

Is it not lamentable to see men like these, it would seem, deceiving themselves, and trying to deceive others. At all events, misquoting and wresting the plain straightforward statements of undeviating truth in the pages of Colonel Howard Vyse's work; and for what? That they may continue to ride the miserable jaded Hypophthegm, that the ratio of the diameter of a circle to its circumference is 1 to 3.14159, &c.

I will here condense the data in Colonel Howard Vyse's work, from which I shall in my next elucidate and describe by diagram the beautiful geometrico-astronomical truths they enable the mind to grasp, in the consideration of the Great Pyramid of Gizeh. They are—

1. The base a square of 764ft. on each side.

2. The angle of the exterior face of the casing stones 51deg. 50min. with the horizon from that base.

3. The perpendicular height of the Pyramid from centre of base to apex when perfect, from elements 1 and 2, 480ft. 9in.

4. The angle of the entrance passage 26deg. 41min. with the horizon.

Other data respecting the interior of the Pyramid and its pavement will be quoted when I proceed to

Digitized by Google

the numerical portion of my proof of 7 as the basis of the structure. Requesting your readers to test the truth of those already given in the interest of true science,—I am, Sir, yours, &c.

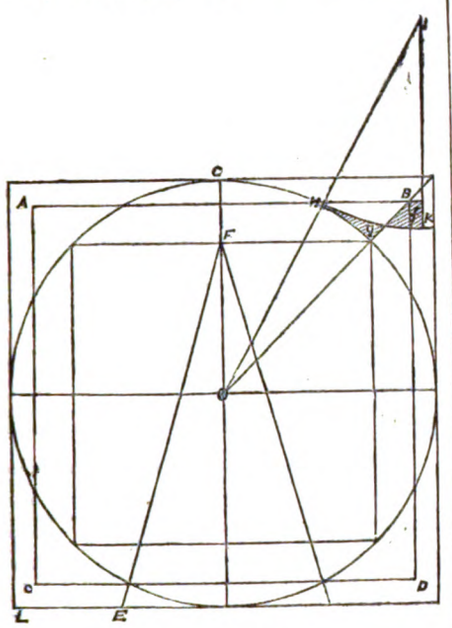
WILLIAM HARVEY.

London, December 19, 1867.

SQUARING THE CIRCLE.

SIR,—I am much surprised to see that Mr. Harvey, after having been proved to be wrong, should still persist in being right, when his error is so glaring that anyone having the slightest knowledge of geometry may easily detect it at first sight. With reference to the method of finding the circumference of the circle as mentioned in my last letter, I have no doubt your other correspondents have found it almost exact. Supposing that way to be correct, the nearest figures I can get to represent the ratio of the diameter to the circumference are—7 1-8th to 22 3-8th, or 57 to 179. I stated in my first letter that I had found the area of a circle 36 feet in diameter to be 1,014 feet and a fraction, but I have since found that the mean of four admeasurements by the way therein described gives just over 1,012¼ feet; and, supposing the side of the square of that circle to be equal to 5-4ths of the side of the inscribed square, or, what is the same thing, 5-8ths of the diagonal of the tangential square (see diagram to letter No. 2), the area of that square would be exactly 1,012½ feet. I have also put a square of the above-mentioned ratio to the same test as I did Mr. Harvey's demonstration (see diagram No. 1 in first letter), and I find it extremely difficult to tell which is the larger of the two spaces corresponding to *f* and *g* in that diagram; and it is certain that if the circle is squared those two spaces will be equal to one another.

The accompanying diagram illustrates what I



have just stated, the two shaded spaces corresponding to *f* and *g* in diagram No. 1, letter No. 1 (the letters O G H and I H K being equal). This diagram requires very careful drawing, otherwise it will be a failure. I may remark, as a somewhat curious coincidence, that if the line E L be drawn, the distance E L being one-fourth of the side of the tangential square, that line apparently crosses the circle at the point of its intersection by the side of what I will call, for the sake of illustration, the square of the circle A B C D at H. As I have not such confidence in my abilities as Mr. Harvey has in his, I do not pretend to have done that which is generally considered impossible, viz., the geometrical quadrature of the circle; but I think I have shown that the square whose side is equal to 5-4ths of the side of the inscribed square, or 5-8ths of the diagonal of the tangential square of any circle, is very nearly the square of that circle. Hoping that my humble efforts may not be uninteresting to the readers of the MECHANICS' MAGAZINE. I am, yours, &c., WM. HAYDEN.

Kent-street, Chichester, Dec. 21, 1867.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10s. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later tqan 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—Messrs. M. and W.—A. R.—R. B. P.—W. P. M.—A. B.—G. E. P.—J. A.—W. H. H. P.—G. S., jun.—T. C.—J. M.—R. K.—J. R. T.—T. H.—J. T. L.—C. D.—B. K.—R. B.—S. R. B.—J. R.—T. B.—S. T. E.—G. D.—B. R. J.—A. H.—G. R. P.—S. L.—Messrs. H. R. and Co.—T. P.—R N.

Meeting for the Week.

TUES.—Royal Institution.—Professor Tyndall on "Heat and Cold" (Juvenile Lectures), 3.

Naval, Military, and Gunnery Items.

WE hear that Captain W. H. Patten Saunders, K.C.G., has submitted an invention for the unplating and destruction of armour-plated ships of war to the representative of His Majesty the Emperor of the French.

MR. BARROW, her Majesty's Consul at Kertch, has been relieved from the charge of the Crimean cemeteries, which are now placed under the superintendence of Colonel Gordon, at Constantinople.

WE are informed that the Commissioners of the International Maritime Havre Exhibition have acceded to the request received from England to extend the time for application for space until February 15, 1868.

WE are happy to state that Mr. E. J. Reed, Chief Constructor of the Navy, who recently met with a severe railway accident in France, has so far recovered as to be able to resume his duties at the Admiralty.

IN No. 4 dock, at Portsmouth, lies the mere shell of an iron vessel from deck-line to keel, stripped of everything except the engine-room bulkheads. This is all that now remains of the once beautiful iron screw-yacht "Fairy," for many years the favourite steam yacht of Her Majesty and the Royal Family.

THE Committee on Naval Affairs of the House of Representatives of America have in contemplation a reduction of the officers and men, as also the number of ships of war of the navy. This will, it is asserted, embrace a withdrawal of vessels from foreign squadrons, reducing them to the minimum number necessary to maintain the honour and dignity of the American Government.

IT appears that the American Gattling gun will be very generally introduced into European armies. According to the "Augsburg Gazette," the agents, Broadwell and Co., in Carlsruhe, have received orders for 1,000 of these engines. Of these, 400 are for France, and 200 for Russia, while Austria, Italy, Belgium, and Holland, are contented with 100 each.

THE twin screw-steamer "Ruahine," 1,503 tons register, and 350-horse power nominal, employed in the mail service across the Pacific, made one of the quickest passages ever known on her last voyage to Panama, having run from Sydney to Wellington (1,250 miles) and from Wellington to Panama (6,670 miles) without stoppage—in all 8,920 nautical miles in 31½ days.

THE greatest activity, says the "Journal du Havre," prevails in the French maritime arsenals. There are at present thirty-nine ships in course of being built, of which four are armour-plated frigates, four coast-guard iron-plated vessels, an armoured floating battery, a screw wooden frigate, six corvettes, screw and not plated, and a screw transport. The fleet really ready for sea comprises 343 steam vessels, and 116 sailing ships; with the thirty-nine in course of construction, the whole will amount to 501 vessels.

THE Marine Department of the Board of Trade has issued a notice that masters who hold certificates of competency bearing the words "of fore-and-aft-rigged vessels" only, are not deemed by the Board as holding certificates appropriate to the station of masters of brigantines, or other square-rigged vessels, and that on and after the 1st inst. superintendents of mercantile marine offices will not be satisfied with the production of these qualified certificates in any cases except in those of *bona fide* fore-and-aft rigged vessels.

THE "Laurel" is a hulk, well known to the seamen of Her Majesty's ships in dock at Portsmouth as a vessel where they can wash their clothes, and where they are also very often made the victims of experimental cooking schemes. It is a remarkable fact that no sooner does one of Her Majesty's ships find itself in dock, or alongside the dockyard, at Portsmouth, than down is sure to come an order from the Admiralty for the trial of some new scheme of cooking, to carry out which it is necessary to take the dinners of a certain number of men from the ship. In nine cases out of ten the invention utterly fails, and the men lose their dinners or eat them half cooked. Why don't the Lords of the Admiralty have a turn and get their dinners cooked there occasionally?

THE first step has been taken by the War-office in forming battalions of volunteers into brigades, by the formation of the 2nd and 4th Tower Hamlets Volunteer Corps into the 1st Tower Hamlets Volunteer Rifle Brigade, and to this amalgamation Her Majesty's consent has been obtained. The 2nd Tower Hamlets formed a battalion with the 8th, and the 4th formerly constituted a battalion with the 6th Corps of the Tower Hamlets; but having raised its strength to the requisite standard to warrant a separate staff, it was formed into an independent battalion, with Lieutenant-Colonel Thomson as its commander, and he is now commandent of the brigade. Lieutenant-Colonel Samuda, M.P., commands the 2nd Corps, while the 8th will go to constitute a brigade with the 26th Middlesex. General satisfaction has been expressed by the volunteers at this amalgamation for all military purposes.

Miscellanea.

A NUGGET weighing over 500oz. has been found near Sandhurst, Victoria.

THE Rev. Dr. Jelf has sent in his resignation of the office of Principal of King's College, London, which he has held for twenty-four years.

THE walrus, which was so recently an object of general interest at the Zoological-gardens, is dead. It was found to be in a state of extreme debility and inanition, and was afflicted with entozoa.

THE number of visitors at the Patent Office Museum, South Kensington, for the week ending December 28, was 9,292; total number since the opening of the museum, free daily (12th May, 1858), 1,222,160.

THE total quantity of gold exported from New Zealand from the years 1853 to 1866, inclusive, was 3,059,451oz.; chrome ore, 5,306 tons 3 cwt. 2 qrs.; coals, 290 tons; copper ore, 2,374 tons 8 cwt.; iron sand, 161 tons 13 cwt.; plumbago 7 tons.

ON the 1st instant the following new Acts of Parliament took effect:—County Court Act, Worship Regulation Act, Factory Act Extension, Agricultural Gangs Act, Merchant Shipping Act, and Sales of Reversion Act.
sions Act.

WE regret to announce the death of Baron Marochetti, which happened somewhat suddenly in Paris, on Saturday last. His many friends will regret in him a most amiable and kindly gentleman, an ardent admirer of art, and an artist, many of whose works are of high and undisputed merit.

AN avalanche of snow came down a few days back at Unterschachen, in the canton of Uri, Switzerland, and carried away a house and its barn. A woman and child and all the animals were swept off. One man, the brother of the proprietor, and a female servant escaped, although it is not mentioned how.

WE hear that an Augusta (Maine) gentleman has recently invented a machine for dressing and blacking boots, which is operated by foot-power. It is stated that this machine can do the work of ten men, and will save much labour in boot and shoe factories. Attached to it are an emery wheel and grindstone.

THE death on Friday last, of Mr. William H. Godson, who had for nearly twenty years occupied the position of superintendent of the London and South-Western Railway, and whose connection with that line dates from its first opening, is announced. He has been suffering from severe illness for several months, and during that time lost his wife.

SEVERAL new streets in Paris have been named after the old masters of French and foreign schools. For instance, two new streets running close to the Parc Monceaux are styled Ruu Rembrandt

Digitized by Google

and Rue Murillo; and we have the names of Veronese, Primatrice, Ph. de Champaigne, Mignord, and Isabey, scattered in different directions of the city.

THE works for bringing the waters of the Vannes to Paris are about to be immediately commenced. The course they will have to follow will be nearly the entire department of the Yonne, and a portion of the Seine-et-Marne, in the neighbourhood of Moret, to reach the grand reservoirs of Montrouge, whence they will be distributed through the quarters of the capital on the left bank of the Seine. The cost of this undertaking is estimated at 20,000,000f.

ACCORDING to the last accounts from the island o St. Thomas, the work of the divers was progressing. A company of American divers, using Heinke's apparatus, were also in operation. The earthquakes, however, entirely unsettled the labour of the negroes, and yellow fever had interfered with the engineering hands. Messrs. Easton and Amos have lost one at work in the dock, and one of Mr. Heinke's men has also died from the effects of the climate.

ON Monday morning last, between two and three o'clock, a portion of rock, weighing several hundredweight, fell with a tremendous crash on the road leading round by the south side of Edinburgh Castle. There was no one near at the time. In the course of the day the burgh engineer made an inspection of the rock, and the attention of the War Department having been directed to the matter, he has given instructions to have any loose portions of rock that remained immediately removed.

COLLECTIONS were made on the 1st instant at all the railway stations, in aid of the accident fund of the Railway Benevolent Institution. Every railway servant contributing 1s. will, in the event of injury by accident, be assisted out of the fund raised, but no applicant is to receive more than £5; and if the sum realized is insufficient to grant them this amount, whatever is collected will be equitably divided among the sufferers. Last year, 11,000 men on 46 different railways became subscribers, and 228 persons, connected with 26 distinct lines, were assisted.

"The Optic Wonder" is the name of a scientific instrument just introduced by the London Stereoscopic Company. It is a creator of apparently solid form out of a mere line. A piece of wire or glass bent to the form of one side of a cup, vase, or anything else is made to faithfully pourtray the whole article. This is done by simple mechanical means, a quick motion gearing being the whole secret. It is really most ingenious, and will efficiently render a wine glass or a beautiful work of art in any material. It illustrates in a striking manner the persistence of vision, and can be rendered instructive as well as highly amusing.

A SPLENDID meteor passed from N.E. to S.W., about 35 deg. above the horizon, and rather slowly, about 7.30 a.m., on the morning of the 1st inst.. It appeared of the size of the full moon, and left a trail of broad, white light, over 60 deg. in length, which was visible for a long time afterwards. It disappeared in a dark mass of clouds fringing the horizon; all the rest of the sky was very clear, the air frosty, and the wind, E., calm. The peculiar form the trail of light took was most singular. From a straight broad line it assumed all the forms of a zig-zag and wave. Here and there the white light was at places, during these movements, as much (to the eye) as 2ft. broad and 6ft. long.

THE treasury building at Washington, it is said, when completed, will have cost nearly 5,000,000 dollars, and will be the finest executive edifice in the world. The greater portion of it is built of Maine granite, and it is proposed to rebuild the remainder with the same material, as the porous sandstone of which it is constructed is disintegrating rapidly. Plans have been prepared for a new War Department building, but Congress will not, probably, vote the requisite appropriations for its construction. The new building for the Department of Agriculture is rapidly approaching completion, and the museum hall will be a prominent attraction for visitors. Specimens of the animals, fruits, products of the soil, and insects of every section of the Republic, will be arranged in classes.

THE first railway for traffic in Prussia was opened in 1838. It appears from the report of Mr. Lowther, our Secretary of Legation at Berlin, that of the railways in use, 225,947 miles belong to the State, and 201,833 miles are private property under the control of the State, and 487,587 are under private administration; this includes 86,598 miles of Prussian railways in foreign territory, but it does not include 12,833 miles of foreign railway on Prussian territory. Of the single provinces the amount of railway in each is as follows: Prussia with 9.17 per cent.; Posen, 6.67; Brandenburg, 13.52; Pomerania, 6.96; Silesia, 20.101; Saxony, 12.26; Westphalia, 12.41; and the Rhine, 18.91.

THE monthly meeting of the Quekett Microscopical Club was held at University College on the 27th ult.; Mr. Arthur E. Durham, president, in the chair. Mr. Burgess read the concluding portion of his paper on the Wools of Commerce, Commercially and Microscopically considered. After reviewing the writings of the previous and present centuries, he explained by the aid of diagrams the result of his own examinations, and regarding the generally received notion that felting properties are due to the imbrications as an error, he maintained that they are entirely due to the natural curvatures of wool, which vary considerably in different growths. A large number of specimens in illustration of this view were placed under microscopes for examination. Mr. Bockett called attention to a form of live-box which he has used with considerable advantage. Eleven members were elected.

M. DOLFUS Assuet has determined to erect a chalet on the summit of Mont Blanc and establish therein a meteorological observatory, which will therefore be placed at an altitude of 4,800 metres above the ordinary level of the earth. Two guides, paid and supported by M. Assuet, will spend the summer there for the purpose of making meteorological observations. During a period of twelve months three guides were kept at the expense of this "savant" in a chalet on the Col de St. Theodule at an altitude of 3,200 metres, that is, at 2,000 or 3,000 feet above the monks of St. Bernard. The value of the meteorological observations made by these men has induced M. Assuet to make a fresh experiment.

THE total production of charcoal-made pig iron for 1867, in France, is estimated at 177,300 tons; of pig made with two combustibles, 78,700 tons; and of pig made with mineral combustible, 886,800 tons; showing a total of about 1,142,800 tons, of the value of £4,805,800. In 1866, the production of charcoal-made pig attained a total of 213,000 tons, while that of pig made with two descriptions of combustible was 89,900 tons, and that of coke-made pig 950,200 tons; showing a total of 1,235,100 tons. The decline in the production of pig in France this year is thus estimated at 110,300 tons. The French production of charcoal-made iron this year is estimated at 41,700 tons; of iron made with two combustibles, 23,400 tons; and of coke-made iron, 735,900 tons; showing a total of 801,000 tons, of the value of £7,393,880. Comparing these results with those for 1866, shows a diminution of 8,700 tons in the quantity of charcoal-made iron, a diminution of 4,700 tons in the quantity of iron made with two combustibles, and an increase of 2,500 tons in that of coke-made iron.

ON visiting the ironworks at Creuzot, Mr. Samuelson, M.P., was conducted over them by M. Schneider, the senior member of the firm. Mr. Samuelson writes:—Notwithstanding his public duties as President of the Corps Législatif, M. Schneider retains the chief direction of the works. During the Session of the Chamber the immediate management on the spot is in the hands of his son (his partner, there being also a small number of other partners with limited liability), but in the recess he resides at Creuzot. After having conducted me for several hours through these vast works, M. Schneider returned to his office to complete and despatch his correspondence, and debate the most minute economical points, items of cost and rates of carriage, with the heads of departments, showing himself, as he expressed it, "*industriel jusqu'au bout des ongles.*" He will forgive me for entering into these details. They are interesting to France and to England, where high political duties are still deemed almost incompatible with an active industrial career.

THE exports of railway iron from the United Kingdom have considerably increased during the past year, notwithstanding the competition of Belgian makers and other circumstances, the total shipments in the ten months ending October 31 having reached 513,071 tons, as compared with 430,141 tons to the corresponding date of 1866, and 361,652 in the first ten months of 1865. The exports to Russia in the ten months ending October 31 this year amounted to no less than 125,513 tons, against 55,396 tons in the corresponding period of 1866, and 37,758 tons in 1865. The United States took the large total of 145,166 tons, as compared with 79,023 tons in 1866, and 44,055 tons in the first ten months of 1865. To British India the exports reached 140,606 tons in the ten months, against 117,737 tons in 1866, and 89,900 tons in 1865. The chief market in which Great Britain has had to meet with Belgian competition has been Russia, but even with that country a much larger business than usual has been done this year by British firms. In the ten years ending 1866 the exports of railway iron from the United Kingdom were as follows: 1857, 457,680 tons; 1858, 433,250 tons; 1859, 528,927 tons; 1860, 453,445 tons; 1861, 377,565 tons; 1862, 400,765 tons; 1863, 446,440 tons; 1864, 408,215 tons; 1865, 434,300 tons; and 1866, 498,595 tons. This year's total will be the largest on record, for the ten months' exports exceed the aggregate returns for 1866.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS,

THE Abridged Specifications of patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1401
BUILDINGS AND BUILDING MATERIALS—1393, 1407, 1426
CHEMISTRY AND PHOTOGRAPHY—1433
CULTIVATION OF THE SOIL, including agricultural implements and machines—None
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1403, 1405
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1386
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1394, 1406, 1440
GENERAL MACHINERY—1388, 1389, 1391, 1392, 1397, 1410, 1414, 1427, 1430, 1481, 1435, 1439, 1444
LIGHTING, HEATING, AND VENTILATING—1382, 1409
METALS, including apparatus for their manufacture—
MISCELLANEOUS—1379, 1380, 1384, 1385, 1387, 1395, 1396, 1397, 1402, 1408, 1412, 1415, 1416, 1418, 1419, 1421, 1424, 1425, 1432, 1437, 1438, 1443, 1445
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1404, 1420, 1429, 1441, 1442
SHIPS AND BOATS, including their fittings—1417, 1423, 1434
STEAM ENGINES—1422
WARFARE—1381, 1400, 1413, 1446

1379 R. ANDREW. *Improvements in communicating between passengers in railway carriages.* Dated May 2, 1867,

The specification of this invention is too voluminous to be quoted here at sufficient length for an intelligible abstract.—Patent completed.

1380 C. RITCHIE. *Improvements in casks.* Dated May 9, 1867.

In performing this invention the inventor introduces into the head of a cask, or similar vessel, a recessed socket, having at the bottom an opening into the cask or vessel, and at the top a lid or cover which may be secured by a lock. Through the opening at the bottom of the socket a tube slides in which a tap is formed. The tap is thus able to slide in and out, so that a cask can safely travel without the tap being removed, but with it pushed back into the socket and enclosed by the cover or lid. In a similar way the bung may be arranged in a socket in the side or bulge of the cask, and the bung may serve also in place of a vent peg, being made tubular for some distance up, and with a hole at the side leading into the internal hollow, so that when the bung is drawn up a short distance, air can enter freely into the cask or vessel, but when it is pushed down, the cask or vessel is closed air-tight.—Patent abandoned.

1381 G. JEFFRIES. *Improvements in apparatus for turning or closing central-fire sporting cartridges.* Dated May 9, 1867.

For this purpose the patentee employs a barrel of the size of the cartridge, and into which the cartridge case is inserted, and its end which is to be turned over against the wad which encloses the charge within it then rests against a grooved disc or end of the barrel which has a tooth within it, and is capable of being rotated by a crank handle as heretofore. In order to press the cartridge up to the grooved rotating disc or end of the barrel, he employs a hand lever jointed to the side of the barrel, and with a forked projection upon it which comes against the head of the cartridge; the two prongs of the fork come on each side of the head of the cartridge, and they are tapered and roughened at the side, so as to jam the head of the cartridge between them and hold it firmly, so as to prevent it turning round, whilst at the same time the lever forces the cartridge up against the turning or closing disc. —Patent completed.

1382 G. M'KENZIE. *Improvements in the manufacture of illuminating gas.* Dated May 10, 1867.

The patentee claims the manufacture of a gas of good illuminating powers by mixing poor gas obtained from inferior bituminous coal with gas obtained by heating mineral oil along with suitable minutely pulverized materials, as described.—Patent completed.

1384 W. BRACEWELL, W. PICKUP, and B. LUND. *Improvements in valves for steam and other fluids.* Dated May 10, 1867,

This invention consists in making the seating of the valve with two or more faces; this seating is provided with a lid or cover with a corresponding number of faces, and the faces of both seating and cover will be so perforated as to allow the cover to be in equilibrium, or otherwise, if preferred. The patentees propose to make valves on the above principle either round, square, oblong, or polygonal, and to arrange them so as to have a separate valve for the admission of steam and for the exhaust; or so that one valve will answer for both admitting the steam and for exhausting.—Patent completed.

1385 R. MELLARD. *Improvements in the construction of machinery for preparing and mixing food for pigs and other animals.* Dated May 10, 1867.

According to this invention a hollow cone is employed, with its apex placed downwards, the interior surface of the cone being provided with a series of cutters or mixing knives or blades. A vertical spindle provided with mixing knives or blades, corresponding with those in the cone, is mounted in the centre of the cone by suitable bearings. At the upper part of the spindle is a revolving cone, which is made to rise and fall by means of suitable mechanism for opening and closing the aperture from the

Digitized by Google

supply of meal. A hopper is suitably placed for the supply of the roots, meal, &c. On the spindle being caused to revolve the objects of the invention are effected.—Patent completed.

1386 J. NORMAN and W. HAY. *Improvements in the manufacture of flour.* Dated May 10, 1867.

This invention consists in drying the meal or flour by preference with the aid of heat, between the processes of grinding and dressing it, and the dressing process is thereby very much facilitated, and the finished flour in the best condition for use by the baker.—Patent completed.

1387 A. COOPER. *Improvements in the manufacture of single and double box pickers for looms.* Dated May 10, 1867.

The patentee claims the manufacture of single and double box pickers for looms of a solid foot made from a piece of hide, felt, or leather, or a solid foot with an enlarged end, and a second piece of hide, felt, or leather, or two or more thin layers of hide, felt, or leather, for forming the leg and cap, the said leg and cap being made, and the leg, cap, and foot secured together (substantially as described and illustrated in the drawings) whereby the pickers are without the exposed edges which are common to ordinary pickers, and are stronger and more durable than ordinary pickers.—Patent completed.

1388 C. JONES. *Improvements in coal mining machinery.* Dated May 10, 1867.

This invention relates to a former invention for improvements in rails, patent dated October 19, 1866 (No. 2708), and consists in forming the said rails with teeth like a toothed rack, and constructing the whole or a portion of the width of the bearing wheels, or other wheels connected with the machine, with teeth to gear into those on the rails, and thereby prevent the machine from moving backwards or forwards when at work. The invention also includes arrangements for making the machines self-feeding; also the use of double or single-acting screw or other jacks for jamming the rails between the floor and roof; also means for carrying, holding down, and keeping up to their work coal mining machines generally. Also a novel arrangement of arms or levers and cutters to plane or pare away coal or other mineral so as to form deep shallow channels or grooves therein.—Patent abandoned.

1389 J. JOHNSON and A. GILES. *Improvements in machines for drying yarns, paper, and fabrics.* Dated May 10, 1867.

This invention consists in the employment of a species of skeleton cylinder mounted upon a horizontal axis, each disc or end of the cylinder having channels or grooves running in a radial direction, and in which frames carrying the material to be dried are placed.—Patent completed.

1391 J. COMBE. *Improvements in machinery for winding cop and warping from cops.* Dated May 10, 1867.

This invention relates to several former patents, dated respectively June 17, 1859 (No. 1466), August 11, 1862 (No. 224), April 14, 1863 (No. 937), and May 19, 1864 (No. 1264). The patentee claims, first, the arranging machinery for winding cops from bobbins in such manner that the bobbins from which the yarn is drawn away be supported on spindles carried in oil cups, so that the bobbins are able to revolve very freely until the tension becomes less than is desired when the bobbins are caused to come in contact with suitable rubbing surfaces. He also claims, in arranging machinery for winding cops, the combining with a tension lever acted on by the yarn a wire or instrument, which, by passing from one side of the centre of the lever to the other, acts on a catch and stops the winding spindle, both when the tension lever rises too high, and when it falls below its proper position. He also claims the arranging machinery for warping from cops with L-shaped weights pressing on the mouths of the eyes through which the yarn from the cops passes, so as to give an uniform tension to the yarn as it comes from the eyes.—Patent completed.

1392 W. SMYTH. *Improvements in machinery or apparatus for navigating the air.* Dated May 10, 1867.

This invention relates to apparatus for navigating the air, a certain novel description of collapsible and expanding apparatus being used in connection with the explosion of mixed gases. The gases used are preferably hydrogen and oxygen, and may be obtained in the air by the decomposition of water by electricity. The patentee proposes also to ignite and explode the gases to produce the expansion and power by an electric current.—Patent completed.

1393 W. CLARK. *Improvements in brick-making machines.* (A communication.) Dated May 11, 1867.

This invention is not described apart from the drawings. —Patent abandoned.

1394 C. MARLOW. *Improvements in the cases for clocks.* Dated May 10, 1867.

This invention consists, essentially, in cementing or lueing together strips of wood round a mould or former, and then submitting the same to pressure by means of a metal strap and bolts or wedges, or otherwise. The cylinders or cases thus formed can be finished in the usual way, or otherwise, as described.—Patent abandoned.

1395 J. A. KNIGHT and C. BASTAND. *An improved self-acting and ventilating nose or feed bag for horses.* (Partly a communication.) Dated May 10, 1867.

This invention consists, mainly, in inserting one or more pieces of perforated zinc or wire gauze in the nosebag of a horse for the purpose of ventilation.—Patent abandoned.

1396 J. REILLY. *An improved system of mechanical aids worked by hand.* Dated May 11, 1867.

This invention is not described apart from the drawings. —Patent completed.

1397 J. WALKER. *Improvements in the construction of the standards and other parts of scales.* Dated May 11, 1867.

One part of this invention consists in a method of constructing the standards of scales or weighing machines. Instead of making the standards in a straight line, the patentee makes the top part of the standards cranked, so as to place the centre or fulcrum of the beam some distance from the lower or remaining portion of the standard, thereby providing ample space for a larger goods scale than could be applied to scales where the fulcrum of the beam rests on the ordinary standard. By this improvement neither the standard nor the beam need be so large as those used for the ordinary stand scales. Another part of the invention consists in fitting the beam with box ends so constructed that at any time required the parts may be immediately disconnected for any readjustment or repair of the centres or bushes. Another part of the invention consists in a mode of connecting the goods and weight scales with the beam.—Patent completed.

1399 G. BROWNING. *Improvements in the construction of button-hole sewing machines.* Dated May 11, 1867.

The patentee claims, first, causing the points of the loop spreaders of button-hole sewing machines (the union button-hole sewing machine) to move towards a line drawn intermediate of the planes of motion of the vibrating needle, in the manner and for the purpose set forth. Second, the arrangement described for effecting a saving in the gimp and silk used in the formation of button-holes. —Patent completed.

1400 J. PIDDINGTON. *Improvements in boring gun barrels and ordnance,* (A communication.) Dated May 11, 1867.

According to this invention the liquid employed in boring gun barrels (usually water and soap) is conveyed to the extremity of the drill or boring tool, and to the very point at which it is in contact with the metal to be removed, by means of a small tube of the same length as the boring tool, and laid parallel therewith. This tube is connected at one end thereof by a flexible joint of caoutchouc with a larger tube which conveys the liquid from a reservoir above the boring engine. The heating of the drill or boring tool, and of the barrel of the gun, is thus very much reduced, and the exterior of the barrel or gun does not require to be kept cool by the application of any liquid. The boring bench is slightly in the direction of the mouth of the barrel or gun, so as to facilitate the escape of the borings, which are removed by means of the current of liquid which is conveyed by the before-mentioned tube, and which liquid in returning carries with it the borings, thus obviating the necessity for the removal of the barrel or gun from the boring bench for the purpose of getting rid of the accumulated borings. The invention is equally applicable to the boring of the barrels of small arms and of ordnance of any calibre.—Patent completed.

1401 J. STEVEN. *Improvements in gauges for steam boilers.* Dated May 11, 1867.

This invention consists, essentially, in forming a hollow annular conical valve seat on the outer end of the upper and lower ducts or passages leading straight or direct into the steam and water spaces of the boiler, each fitted with a corresponding conical pointed screw hand plug or spindle working steam-tight on the said seat, and through a screw and packing gland fitted on the front part of the hollow chamber of the metallic socket pieces carrying the upper and lower ends of the glass tube of the gauge; and, further, in the use of two ducts, passages, or channels, closed at one end, formed in the "blow-off" nozzle, the one leading into the small chamber at the lower end of the glass tube, or in direct communication with the interior of the tube, and the other leading out through the blow-off nozzle or "nose-cock" with or having a small division or thickness of metal between them, through which a lateral orifice is formed leading from the former into the latter direct, having fitted or applied thereto a conical seat and pointed screw, tap, or valve, with screw and stuffing gland controlled at pleasure by a handle outside (as described in reference to the outlet steam and water valves), so as to allow the water in clearing out or "blowing through" the gauge to escape down the first duct and out through the lateral opening controlled by valve-plug and off by the outlet passage open to the air at the blow-off nozzle; so that when these steam, water, and blow-off valves are shut, or not required for the time being, the valve surfaces are not exposed to the pressure or action of the steam or water, while the narrow annular surfaces really necessary in this construction of tap or valves, and their extreme simplicity, render the whole instrument most durable, and with little or no liability to leakage or derangement in its action.—Patent abandoned.

1402 T. NELSON. *Improvements in the manufacture of cards.* Dated May 11, 1867.

The patentee claims the manufacture of cards, tablets, and other articles from which marks made with water colours, ink, or pencil may be repeatedly erased by moisture without injury to the surface, by coating cards, tablets, and other articles with soluble silicate, and then exposing them to heat, as described.—Patent completed.

1403 W. CLARK. *Improvements in bleaching textile materials or fibres.* (A communication.) Dated May 11, 1867.

According to this invention, when the fibres of wood are to be operated upon, the wood, after being split up, is deprived of the bark, the knots and heart are then cut up diagonally into pieces of about 3in. square. It is then subjected to the action of vertical stones or edge runners, turning in an enclosed space for containing the material; these stones, by the aid of water and quicklime, in the proportion of from 15 to 18 per cent. of the wood treated, effect the disaggregation of the wood, and roughly separate the filaments. The wood after being cut up, as above described, should be immersed for about a month in water saturated with lime, before being acted on by the stones, as above mentioned, whereby the disaggregation of the fibres is greatly facilitated. The wood should remain in the liquid until it acquires sufficient weight to sink to the bottom, being stirred and turned from time to time. The wood being thus crushed is placed in heaps on an inclined surface to facilitate draining off the lime water it contains, and after being macerated for several days in this manner it is placed in a washing and subdividing cylinder, whence it emerges bleached.—Patent abandoned.

1404 J. WATKINS. *Improvements in axles for carriages.* Dated May 11, 1867.

The patentee claims connecting the axle boxes of carriage axles to the arm of the axle by means of a revolving collar, bush, or socket applied to and rotating upon the cone or front collar of the said arm, the said revolving collar, bush, or socket bearing in its rotation between the ordinary or back collar and a nut, or a flanged nut screwed or otherwise fastened to the arm of the axles, substantially as described.—Patent completed.

1405 J. W. DALBY and P. CONSTANTINE. *An improved species of yarns.* Dated May 11, 1867.

This improved species of yarn consists of two important points. The first point is the spiral or double spiral coil or twist put on at any given intervals upon an ordinary thread of yarn; such coiled threads or yarns may each be of distinct colours, if wished, to simply alternate colours, thus producing, when woven, and in the piece, a pleasing effect. The second feature of the invention consists in the apparatus by which the inventors effect this result, and this consists, viz., of a sectional wheel placed under the back rollers, and which in its revolutions retards at given intervals the passage of the same. In front of the front rollers they place an additional creel board, which carries the coloured threads of yarns, and these are passed by means of wires so as to perform a junction with the thread or yarn emitted from the front rollers betwixt the latter and the flyer, the number of such colours being of course dependent upon the pattern required.—Patent abandoned.

1406 W. R. LAKE. *An improved castor for tables, chairs, and other articles of furniture.* (A communication.) Dated May 11, 1867.

This invention consists in the employment in combination with the ordinary parts of castors of an auxiliary anti-friction roller with a convex periphery supported to turn freely upon a stud or pin attached to the frame of the castor, and arranged to roll upon a concave surface formed upon the foot or leg to which the castor is attached, or upon a circular plate secured upon the same.—Patent abandoned.

1407 W. R. LAKE. *An improved mode of constructing metal cocks, faucets, and other similar articles.* (A communication.) Dated May 11, 1867.

This invention consists, chiefly, in forming a cock, faucet, or other article, in parts or sections which are cut or stamped from sheet brass or other suitable metal, and united by brazing and soldering, and also in the employment in combination with the same of a hollow plug formed of sheet brass or other suitable metal.—Patent completed.

1408 G. A. NEUMEIJER. *Improvements in gunpowder for mining purposes.* Dated May 13, 1867.

This invention has reference to certain Improvements in gunpowder for mining and war purposes, for which letters patent granted to A. Klein, June 17, 1863 (No. 1636), being a communication made to him from abroad by the present patentee. Instead of soaking the soda-lye, and generally preparing and incorporating the ingredients, as described in the specification to the said letters patent, the patentee proceeds as follows:—He mixes about 72 parts by weight of saltpetre with about 18 parts by weight of charcoal prepared in the ordinary manner, and from any suitable description of wood, and to these he adds about 10 parts by weight of flowers of sulphur to form together 100 parts by weight of gunpowder. These ingredients are not incorporated in the ordinary manner, but are placed in a cool cylinder of wood, copper, or other suitable material, through which passes a revolving shaft having a number of radial arms, and which may be arranged in any suitable known manner, or any other known form of apparatus having a similar stirring or mixing action may be employed. Together with the above ingredients he introduces water into the said cylinder in the proportion of about 40 parts by weight of water to about 100 parts by weight of the compound, and he then subjects the compound to the incorporating action of the revolving arms for about fifteen minutes, after which the compound is removed from the cylinder and dried without being subjected to the operation of granulating, and it is then fit for use. Such powder when burnt in an unconfined space will have a considerable residue, but when ignited in a confined space will leave considerably less residue than ordinary gunpowder.—Patent completed.

1409 J. G. N. ALLEYNE. *Improvements in puddling furnaces.* Dated May 13, 1867.

The patentee claims, first, so constructing the beds of puddling and other furnaces that the outer surface of the bottom and sides thereof are enclosed in a chamber, the bottom of which is a water tank or trough forming hydraulic joints with the sides, into which chamber a jet or jets of air or of water spray, or of air and water spray combined, is or are forced through one or more pipes, while the hot air and water spray or steam are caused to pass away through one or more other pipes, substantially as described. Second, constructing rotating furnace beds with flanges dipping into a water tank or trough below the bed, so as, by means of hydraulic joints, to form an enclosed space surrounding the outer surface of such bed, into which space a jet or jets of air, or of water spray, or of air and water spay combined, is or are forced, substantially as and for the purposes set forth with reference to the drawings. —Patent completed.

1410 R. H. PADBURY. *A new or improved shuttle for sewing machines.* Dated May 13, 1867.

This invention consists in the construction of shuttles for sewing machines in two parts, and in the following manner:—The first part, or the shuttle proper, is made of one solid piece of metal; it is pointed in the ordinary way, and is bored to receive a reel; the back is slotted, which acts as a bar to guide the cotton from the reel, and there is a slot on the top for the spring which bears on the reel. The second part or heel of the shuttle is swivelled on the tension plate, and fits into the rear end of the solid shuttle; it is drilled, and countersunk on its inner end to receive one end of the reel spindle, the other end of which works in the nose end of the solid shuttle drilled and countersunk in a similar manner. The tension plate has a notch or recess cut in it, which, when the plate is closed, passes over or on a stud or ridge on the solid shuttle, and the heel end is thus prevented from leaving the shuttle, and at the same time the reel is kept in position. A ridge is also formed on the forward end of the tension plate which, when closed, springs into a recess on the forward end of the shuttle, and the plate is thus prevented from opening.—Patent abandoned.

1411 G. LUNGE. *Improvements in the preparation of ores, metals, and other substances for working in furnaces.* Dated May 13, 1867.

This invention consists in a certain mode of treatment whereby the smelting, subliming, or working of substances in a state of sand or minute division is rendered practicable in furnaces in which such operations have hitherto been impossible, principally owing to the fact that such substances are apt to fall through the fuel and choke the furnace. This object is effected by combining such substances, as metal or ores in any state, oxides, cinders, slags, common salt, silica, or any other materials or mixtures of materials, when in too small a state to work, smelt, or sublime, in a draught or blast furnace, with coal, such combination being formed into lumps or pieces sufficiently large to work in furnaces of that description. The lumps of combined materials are then converted into coke by any of the known means.—Patent abandoned.

1412 H. A. BONNEVILLE. *An improved washing powder.* (A communication.) Dated May 13, 1867.

This invention relates to a compound fit for washing purposes, and consists, in a mixture of maize flour, of the cakes of the arachis or arachidna quadrifolia, of sesamum, or of poppy, and of sub-carbonate of soda, or artificial soda, to which mixture is added, for the washing of rough materials, a sixth of non-hydraulic lime. This powder

Digitized by Google

is steeped in water when required for use.—Patent completed.

1413 J. LEETCH. *Improvements in cartridge holders.* Dated May 13, 1867.

This invention consists in the use of elastic or flexible pouches, which are attached to a coat, waistcoat, or other garment, or to a separate belt. Each pouch receives one cartridge, and holds the same in such a manner as to prevent its being injured or accidentally displaced, but will allow its ready removal when required for use.—Patent abandoned.

1414 C. EASTWOOD. *Improvements in looms for weavinr.* Dated May 13, 1867.

This invention relates to the "letting-off motion" in looms for weaving, or to the self-acting means or apparatus employed for supplying warp from the warp beam in regular order or suitable quantity as it is taken up in or by the process of weaving. The inventor applies a star wheel or notch plate (instead of the brake pulley) with a spring catch or stop to enter the notches in succession, and hold therein until forced out by excess of tension on the warp. The number of notches in this plate or wheel correspond to the number of teeth in the ordinary catch wheel employed in this apparatus. By this invention the inventor is enabled to obtain uniform tension on the warp, and render such apparatus less liable to be tampered with by the attendants than heretofore.—Patent abandoned.

1415 W. CORMACK. *Improvements in means and apparatus for effecting the revivification of animal and vegetable charcoal.* Dated May 13, 1867.

The object of this invention is to effect revivification in less time and at less cost than by calcining or burning it, and the inventor accomplishes this by passing superheated steam at or about 500 deg. Fah. through or amongst a mass of the inert charcoal, the said charcoal being contained in a specially constructed apparatus. Or instead of superheated steam he employs superheated air for the same purpose at a temperature of between 300 and 350 deg. Fah.—Patent abandoned.

1416 W. E. DE BOURRAU. *Improvements in evaporators for concentrating saccharine fluids.* Dated May 13, 1867.

This improved evaporator is composed of a basin or trough to receive the syrup, and carrying above each of its ends suitable bearings for supporting a hollow axis; the end of each hollow axis projects a short distance over the end of the trough, and carries a hollow steam chest which is concentric with the axis, and is of such a diameter as to pass down nearly to the bottom of the trough or basin. The ends of the two steam chests, which are opposite one another, are connected by a number of straight pipes which pass from the end of one chest near its outer circumference to the outer circumference of the end of the other steam chest; a central pipe is also employed to connect these two ends of the steam chest, in order to give strength. The pipes which connect the outer circumference of the ends of the two steam chests are at the centre of their length stayed to one another and to the central pipe by a ring placed within the circle of pipes, so that each pipe rests against and is supported by the ring, and the ring is connected by radial arms to the centre pipe above mentioned. The steam chests are of copper, and steam is admitted to them through their hollow axis. Within each steam chest, and at a short distance in front of the open end of its hollow axis, is fixed a disc, against which the steam impinges as it enters the steam chest, and the steam is thus thoroughly dispersed. Around the outer circumference of each steam chest, pockets or recesses are formed in which the condensed water collects, and from which the water is led away by pipes passing out through the axis. On the hollow axis carrying one of the steam chests is a toothed wheel, into which gears a pinion to which a rotary motion is imparted, and thus a rotary motion is given to both steam chests, and the pipes which pass from one chest to the other as they are carried round with the chests will be alternately dipped into the fluid in the basin or trough and raised out therefrom.—Patent abandoned.

1417 J. W. BUTLER. *Improvements in the construction of armour-plated ships and batteries.* Dated May 13, 1867.

The patentee claims backing the armour-plating with tubes with their axes at right angles, or nearly so, to the armour-plate, as described.—Patent completed.

1418 M. D. ROGERS and J. WILSON. *An improved fire-escape.* Dated May 13, 1867.

This invention consists in constructing a fire-escape in the following manner, that is to say:—To the upper windows, by preference, and to the brickwork at each side thereof, and outside of the building, the inventors hinge a bar or "davit" by its lower end, and to the upper end of each bar or davit aforesaid they connect one end of a chain or fireproof rope, the other end whereof is connected to a counterbalance weight sufficiently heavy to balance a cage or balcony slung by its ends, or suspended from the upper ends of the aforesaid bars or davits. They propose to pass a tube or tubes through the several floors of a house or other building, and allow the counterbalance weights before mentioned to pass freely up and down the said tubes, so that, supposing the fire-escape to be in use, and persons to have entered the cage or balcony, they can lower themselves down by means of a chain, or other suitable contrivance, and when they get out, the cage or balcony will be lifted up by the counterbalance weights before mentioned, thus rendering the fire-escape self-acting. The tubes containing the counterbalance weights the inventors propose to connect by their lower ends with a water main, fitted with cocks for establishing a communication with the main, when it is required to use the aforesaid tubes for extinguishing fire in a house or other building, and they perforate the said tubes for the escape of water into the rooms of a house, the said perforations being made near the ceiling by preference; by these means a large body of water may be discharged inside a house. The aforesaid tubes when not charged with water serve to carry off the vitiated air from rooms, the air entering the tubes by the perforations therein, and passing off through the upper ends thereof into the open air.—Patent abandoned.

1419 E. FIELD. *Improvement in apparatus for generating and condensing steam.* Dated May 13, 1867.

The patentee claims, first, in apparatus for generating steam, the use or employment, in combination with pendant water tubes or series of pipes or tubes placed at an inclination from the horizontal, and so arranged that their higher extremities communicate with another pipe, tube, or chamber, or other pipes, tubes, or chambers constituting a steam space or steam spaces, the lower ends of such inclined pipes or tubes being likewise a communication with another pipe, tube, or chamber, or other pipes, tubes, or chambers forming a water space or water spaces, in which sediment may collect or deposit, substantially as described. Second, in apparatus for generating and condensing steam, the use or employment, substantially as set forth, of the means described for preventing the deposit of saline, earthy, and other matters.—Patent completed.

1420 J. CLARK. *Improvements in railway brakes.* Dated May 13, 1867.

This invention relates in part to continuous brakes, or those applied in several carriages, and in part to ordinary brakes in single vehicles of the train, and to the means of applying the same. The objects of this invention are, first, to obtain the power for applying the brakes from the axles or wheels of the train when in motion. Second, to regulate the power so obtained as required. Third, to introduce between the force applied and the brake blocks self-adjusting motion for compensating the wear of the blocks. Fourth, to prevent the jar or pressure on the carriages when the blocks are applied. And, lastly, to improve certain parts of the mechanism by which the ordinary blocks are applied. The specification of the invention is too voluminous to be quoted here in detail.—Patent completed.

1421 W. SODO. *A new universal floating apparatus.* Dated May 13, 1867.

This invention has for its object an improved method of and apparatus for drawing liquor or liquids from casks or vessels of any description, and the refining of such liquor or liquids. The apparatus to be used consists of a float made of wood, copper, and india-rubber, or any other material suitable for the purpose, and is connected to an india-rubber tube; at the other end of the india-rubber tube is connected a leaden pipe or pipes; the said leaden pipe or pipes is connected to a pump where the liquor or liquids are drawn through the float from the interior of any casks, vessel, or vessels of any description.—Patent abandoned.

1422 A. H. COLLES. *Improvements in apparatus for signalling between passengers.* Dated May 14, 1867.

This invention relates to apparatus for effecting communication between guard and driver, or between the passengers and either the guard or driver, or both, and consists in means of signalling danger or calling attention for assistance in a railway carriage compartment. The improvements consist in the application of two cords running along the top of each carriage, equi-distant on both sides of the longitudinal centre of the carriage; these cords are firmly secured to one end of the carriage, their opposite ends being caused to coil round the axle of a pulley or drum, one on each carriage, situated midway between the two cords; over these pulleys or drums a through cord passes, being coupled up in lengths so as to form a continuous connection between the guard's van and engine, a certain amount of slack being allowed for the varying distances of the carriages. This cord is caused to press upon such pulleys or drum by means of a bar or other equivalent, one end of which is attached to an alarum in the guard's van, and the other end to the handle of a steam whistle on the engine. The separate lengths of cords with which each carriage is provided, and which are connected to the axle of the pulley or drum before mentioned, are connected with pendant strings or chains running over small guide pulleys, and protruding through the roof of the carriage, two in each compartment, each one terminating in a button and tassel, the button being constructed so as to press against and be attached to an ornamental piece of paper arranged to cover it, so that when the tassel is pulled for giving an alarm, the paper is torn or destroyed, thereby indicating the compartment in which the alarm was given. To each of these pendant cords a catch is secured, which is in connection with a spring and bell crank lever, the said lever being provided with a signal or semaphore which, when the pendant cord is pulled, becomes released, so as to project and signal the carriage from whence the alarm was communicated. If a passenger desires to raise an alarm, the tassel secured to the length of rope coiled round the axle of the pulley or drum over which the continuous rope passes is pulled down in the carriage, which immediately transmits motion through the medium of the axle and large pulley or drum to the rope communicating an alarm on the engine, or in the guard's van, and simultaneously the catch holding the spring semaphore is released, and the signal remains extended to indicate the position of the required assistance.—Patent completed.

1423 C. RANDOLPH. *Improvements in apparatus for propelling vessels.* Dated May 14, 1867.

This invention is not described apart from the drawings.—Patent completed.

1424 B. BARRETT and H. MACKENZIE. *Improvements in egg boilers.* Dated May 14, 1867.

Egg boilers for the table, as ordinarily constructed, consist of a small boiler or vessel with a lid or cover in which vessel the eggs are boiled. The said boiler or vessel is supported on legs, and is heated by a lamp placed on a stand underneath the said boiler, the lamp stand being carried by the legs of the boiler. This invention consists of the improvements in or additions to the said egg boilers hereinafter described. The patentees provide the edge of the lamp stand with two, four, or other required number of small radial platforms or supports to carry the egg cups. These supports may be made in one piece with the lamp stand, or soldered thereto. Each of the said supports has a small peg fixed to a conical seat at its upper side, upon which the hollow foot of the egg cup fits. The egg cups are thereby prevented from falling from the platforms or supports at the base of the egg boiler. They also provide the egg boiler with a minute or sand glass for indicating the time for boiling the eggs.—Patent completed.

1425 J. J. BASTIN and L. A. BAUM. *The use of all kind of industry.* Dated May 14, 1867.

Provisional protection has not been granted for this invention.

1426 J. G. JENNINGS. *Improvements in water-closets and sinks.* Dated May 14, 1867.

According to this invention the patentee arranges water-closets in such manner that, whilst the excrementitious matters which the basin may receive, together with the small quantity of water which the basin holds, are discharged into a receiver, so as to be applicable for use as a manure; the comparatively large quantities of water which are used to scour the basin are kept out of this receiver, and directed away into a sewer or otherwise, as may be desired, but without mixing with and diluting the excrementitious matter, which is consequently discharged almost in an undiluted state into the receiver, whatever be the quantity of water used to cleanse the pan. For this purpose the patentee employs a pan with a valve at the bottom, and when this valve is opened the matters in the pan press into the manure receiver. The same act of opening the valve of the pan also in the usual way opens a valve for the supply of the scouring water, and this water supply valve is so arranged, as is well understood as to remain open for a regulated time. The scouring water is, however, prevented from passing into the pan so long as the valve of the pan is closed; the scouring water is admitted and the excess passes away by a side opening from the pan, leaving therein only a small quantity of water, say a depth of half an inch, but more or less, as may be desired, and sufficient to prevent the adhesion of soil.—Patent completed.

1427 A. M. CLARK. *Improvements in the means of raising liquids.* (A communication). Dated May 14, 1867.

This invention relates to an improved method of raising fermented and other liquids by the pressure of carbonic acid gas, which latter becomes compressed in proportion as it is used. The improvements are especially applicable for raising beer from the cellar, instead of by the ordinary mode. The carbonic acid gas is produced pure by the reaction in a wet state of tartaric acid on bicarbonate of soda; in this manner the inventor is enabled to dispense with washing and purifying apparatus. The reaction is operated in any suitable chamber or capacity of sufficient strength, the affinity of the acid for the salt being such that a relatively considerable pressure is produced by the generation of the gas. The generator may contain ice for cooling the carbonic acid gas, and it is also enclosed in strips of cloth, coal, or sawdust, or other non-conductor of heat. The carbonic acid gas produced under pressure in the generator passes into a condensing reservoir provided with a pressure gauge, and is supplied to the cask by the aid of a cock and supply valve for acting on the beer or other liquid to be raised and supplied to the counter or other point. For the purpose of cooling the beer, it is usual to enclose the ascending pipe in another, the space between containing ice; or a current of cold water is sometimes applied; from this arrangement it often results that the beer is kept too cool, as the temperature at which it should be consumed is about 50 deg., above or below which it loses its qualities. To obviate this the inventor proposes to surround the ascending pipe with strips of cloth or felt, and a layer of pulverized coal, sand, sawdust, or other non-conducting material; in this manner the beer may be applied to the tap at the same temperature.—Patent completed.

1429 A. V. NEWTON. *Improvements in axle-boxes and bearings.* (A communication.) Dated May 14, 1867.

This invention relates, first, to the reduction of friction by the employment of pasteboard saturated with oil, and then subjected to pressure and inserted in suitable recesses in journal boxes and other bearings. Second, to the combination with the metallic or other non-absorbent bearing surfaces of axle and journal boxes or their linings of wood in the form of strips inserted within the same in an intermediate or intervening manner relatively to the metallic or other non-absorbent bearing surface. The said strips may either be saturated with petroleum, or other lubricating oil or matter, previous to insertion, or serve by their absorbent character to convey lubricating matter from a suitable supply to the axle or shaft during its rotation to and throughout the bearing, and, preferably, they will extend to the ends of the same. Thirdly, to a novel construction of journal or axle box or lining thereof in which anti-friction strips are disposed in an intervening or intermediate manner, so as to form a portion of the bearing in combination with the harder material of which the box or lining piece is composed, the said strips being cast, slidden, or otherwise fitted within the box or its lining, so as to form end presentations on opposite sides or ends of the bearings successively or alternately to lubricate the shoulder and collar of the axle or shaft.—Patent completed.

1430 J. C. ELLISON. *A machine or apparatus for removing the card boards from the folds of fabrics.* Dated May 15, 1867.

This apparatus consists of a rectangular frame or box of suitable size to receive a piece of fabric with the cardboards, metallic plates, or other substances which may be used placed betwixt the folds thereof. The bottom of this frame or box constitutes a movable table capable of supporting and raising the folded fabric with the projecting ends of the cardboards or metallic plates into contact with reciprocatory hooks, pushers, fingers, or pins, which, at each stroke, catch on the edge of the top cardboard and remove it a suitable distance, to be seized by a pair of rollers which draw it out of or from the fold of the fabric, the said fold being held in position by fingers caused to enter in betwixt the folds at the proper time and hold them against the crease until the cardboard or plate is withdrawn therefrom; consequently, at each reciprocation of the said hooks, pushers, fingers, or pins one of the cardboards or plates is removed alternately in opposite directions from the folds of the fabric, which remains in its folded state.—Patent completed.

1431 C. BRAZIL and R. GRIME. *Improved arrangements and apparatus for wetting and drying wefts.* Dated May 15 1867.

This invention consists in improved arrangements and apparatus for wetting or preparing weft for wet weaving, whereby the patentees dispense with the necessity of submitting the cops to mechanical pressure, or subjecting them to the action of centrifugal force for the purpose of expelling or getting rid of the superfluous water. The cops of weft must be first skewered, as in the present or general practice, or they must have been spun on metallic tubes. They place the cops in a strong vessel capable of being made steam tight, and cover them with the usual mixture of soap and water, after which they close the vessel and supply steam of about twenty to thirty pounds pressure to the square inch to the interior, which pressure forces the soap and water into and through the cops.—Patent completed.

1432 H. C. BAILDON. *Improvements in "nature printing."* Dated May 15, 1867.

The patentee claims the production of fac-simile copies of fronds of ferns, leaves of plants, and other suitable natural objects, by taking impressions on transfer paper direct from a frond or leaf, or other natural object, and transferring the same on to lithographic stones, and printing therefrom, as described.—Patent completed.

Digitized by Google

1433 E. SMITH. *Improvements in obtaining violet colouring matters.* Dated May 15, 1867.

The patentee claims the producing of violet colouring matters by the action on rosaniline, or on a salt thereof, of chloride of mesityl, or of a bromine derivative of oil obtained from rubber or gutta percha, substantially as described.—Patent completed.

1434 F. BONNEY. *Improvements in the construction of ships and boats.* Dated May 15, 1867.

This invention consists in building ships or boats with semicircular or projecting angular sides, gradually curving upwards from midships to the stem and stern, so as to extend throughout the entire length of the vessel immediately above the water line, by which construction the said vessels, on inclining to either side of a horizontal position, through the action of the wind or waves, shall present an increased superficial displacement and consequent controlling action in the lateral and longitudinal movements of the said vessels, additional room being obtained through the medium of the extended sides and flush deck.—Patent abandoned.

1435 C. PERRY. *An improved machine for flattening hackle pins.* Dated May 15, 1867.

This invention relates to an improved machine for flattening hackle pins or comb teeth employed in machines for combing wool or other fibrous substances, or the wire therefor. This machine is constructed so that it can be worked by a belt from a drum of a main shaft to a pulley fixed upon its own shaft; upon the latter shaft a spur wheel and fly wheel are keyed. The spur wheel last mentioned gears with a larger wheel keyed upon a second shaft above it; both of these shafts are mounted in bearings in a suitable or oblong frame, across which they run transversely. The frame is formed with an opening in the centre, the gearing wheels, fly wheel, and driving pulley being placed upon one side. On the top of the frame, over the space between the two sides, the patentee mounts a lever beam. Upon the upper cross shaft, and under the long end of the lever beam, he fixes an eccentric wheel, and near the long end of the said beam he fits a bearing pulley. This bearing pulley is mounted in bearings at the lower end of a screw shaft or spindle which passes through the beam, and is held in position by two lock nuts, one above and one below the same; by means of these nuts the bearing pulley can be raised and lowered, and fixed as required, so as to adjust the rise of the long end of the lever as it is worked up and down by the eccentric before mentioned. For further regulating the rise and fall of the lever he mounts it in adjusting plummer blocks, so that the centre of motion may be raised or lowered by bearing screws or adjusting wedges, or partly by each. At the short end or crushing head of the lever beam he forms proper spaces for receiving a steel die, and in a tool bed or block immediately under the same he fits a second steel die. The tool bed or block is adjustable horizontally and vertically. The latter adjustment is effected by means of a set screw or screws and adjusting wedges. The pins or comb teeth or wire therefore are placed between the dies in the beam head and tool bed. On giving motion to the eccentric the beam will be caused to rise and fall, and compress or flatten the pins, teeth, or wire to any required degree, which can be regulated, first, by altering the clock nuts on the screwed spindle in the long end of the beam; second, by varying the centre of motion of the lever by the plummer block adjustment before described; or, third, by altering the level of the tool bed by means of the screw and wedge bearing pieces.—Patent completed.

1437 W. D. TATE. *Improvements in apparatus for stopping bottles and other vessels.* Dated May 15, 1862.

For this purpose the inventor employs a tube or socket which is conveniently made of thin metal, and he springs on to the lower end of it a short piece of india-rubber tube, which naturally is somewhat smaller in internal diameter than the socket. The socket, with the india-rubber tube covering it, is forced into the mouth of the bottle or vessel, like a cork, and the india-rubber gives a sufficient elasticity to ensure a tight joint between the socket and the neck of the bottle or vessel. The bottle or vessel being thus fitted is closed by a stopper, made by preference of glass or earthenware; the stem of this stopper is of such a size as to pass quite freely down through the socket, but it is embraced by the free end of the india-rubber tube which projects somewhat beyond the socket, and so an air-tight joint is made. To obtain access to the contents of the bottle or vessel, the stopper is drawn out, leaving the socket and india-rubber tube still in the neck of the bottle or vessel. The stopper will always come out very easily, the india-rubber tube yielding when a slight force is applied.—Patent abandoned.

1438 J. JOHNSON. *Improvements in submarine longs.* Dated May 15, 1867.

This invention is not described apart from the drawings. —Patent completed.

1439 G. NIMMO. *An improvement in metal wheels.* Dated May 15, 1867.

In performing this invention the patentee takes a metal ring of wrought iron or steel to form the tire of the wheel; the same may be a new ring, or it may be an old wrought-iron wheel or tire; and he bores, cuts, or forms round, oblong, or polygonal holes into or through the same at suitable distances apart around the periphery, and he turns or cuts grooves in the cylindrical surface of such ring near the edges thereof; the said grooves are of any desired sectional shape; he, however, prefers to make them V-shaped. He prepares a mould either in sand or metal of a shape corresponding to the exterior of the intended wheel, and adapted to receive the said metal ring, and he places each metal ring in the said mould, and casts around the same iron or steel, or a mixture thereof, of the desired character, and it forms a complete union with such metal ring, in consequence of the grooves and holes in the same, so that the cast metal tire and wrought metal ring are inseparable, thus obtaining the lightness and strength of the wrought metal wheel, and the durability under wear of the cast metal surface. The wrought ring may be heated before being placed in the mould, and a flux employed to effect a more firm union of the metals.—Patent completed.

1440 A. V. NEWTON. *Improvements in billiard tables.* (A communication.) Dated May 15, 1867.

It has been ascertained by experiment that when vulcanized india-rubber is entirely confined laterally, so that it cannot spread laterally, the reacting force which it will impart is nearly equal to the direct force with which it was struck; but that if not so held laterally when struck it will spread, and for that reason fail to react with sufficient force. It is on this fact that the first part of the present invention is based, and with this view the said invention consists of a new manufacture of billiard table cushions, composed of alternate layers of soft vulcanized india-rubber and two or more of cloth or other thin pliable substance which will not readily stretch, previously coated with india-rubber, the whole being united whilst the india-rubber is in the green or plastic state, and then vulcanized. The two or more layers of cloth or equivalent substance have the effect of binding together the interposed layers, so as to prevent the spread of the india-rubber when the cushion is struck by a ball, thereby obtaining a greater reacting force than by cushions differently constructed. The face of the cushion inclines inward, so that when struck by the ball the reacting force of the cushion will be exerted on the ball above the horizontal plane of its axis. This is to prevent the ball from jumping, as it is termed. This form of cushion admits of being made sufficiently low that the player may reach the ball with the cue when close to the cushion. Another improvement in this branch of the invention consists in making billiard tables with reversible cushions, with both faces inclining inwards from parallel planes at right angles to the top surface, by reason of which form cushions may be produced with a materially less weight of india-rubber than by any plan heretofore known, and with an equal thickness where the elastic force is required. That part of the invention which refers to converting billiard tables into dining tables cannot be described without reference to the drawings.—Patent completed.

1441 G. COLES, J. A. JAQUES, and J. A. FANSHAWE. *Improvements in wheeled carriages.* Dated May 15, 1867.

The object of this invention is to prevent the shocks or jars usually experienced in wheeled carriages, as at present constructed, and the invention consists in constructing carriages with elastic or flexible joints, the different joints or parts being connected by vulcanized india-rubber, or its compound.—Patent completed.

1442 G. COLES, J. A. JAQUES, and J. A. FANSHAWE. *Improvements applicable to the permanent way of railways.* Dated May 15, 1867.

This invention consists in placing under the rail, and between it and the chair or sleeper, a compound elastic plate or pad consisting of two or more thin metal sheets or discs coated with brass, and between each plate is placed a sheet of vulcanized india-rubber or its compounds. This arrangement prevents the usual violent shocks or jars which are experienced in railway travelling. —Patent completed.

1443 E. EDWARDS *Improvements in apparatus for treating mineral substances.* Dated May 15, 1867.

This invention consists of a box or cistern filled with water, and having one part of the top open, and fitted with a frame carrying a perforated plate or wire screen, upon which the substance to be treated is fed from a hopper. The other part of the top is closed and inclined downwards, and has an aperture closed by some flexible substance, upon which is screwed a block plate carrying a block upon which one or more cams strike, fixed to a shaft revolving in a carefully adjusted position above. When the cistern is filled with water, each depression causes the water to rise suddenly through the perforated plate or screen, and thus to throw up the mineral substances resting upon it. When the cam leaves the block, the pressure of the water below, increased by the inclination of the top of the cistern, causes the flexible substance to rise slowly until again depressed by a cam. The mineral substance thus has time to fall slowly through the water, the heavier particles falling first upon the screen and forming the lower layer and the lighter particles forming the upper layer. This upper part is removed by rakes or scrapers carried upon a frame running on wheels and driven by a crank upon the driving shaft.—Patent completed.

1444 J. HARPER. *Improvements in single cylinder printing machines.* Dated May 16, 1867.

These improvements apply, principally, to the inking apparatus of single-cylinder printing machines. Instead of driving the "doctor" roller (which furnishes the composition roller with ink) by means of bevil gearing and shaft placed outside the framing of the machine in connection with the spur-wheel shaft, as usual, the inventor drives the said roller by means of gearing placed entirely within the said framing, and actuated directly from the main driving shaft, so that the machine occupies less space, and the danger of outside gearing is avoided. Part of this gearing consists of a wheel having spur teeth round its circumference, and also three concentric circles or segments of teeth on its face, so that by sliding a pinion into gear with one or other of these circles or segments of teeth, the doctor roller can be driven at a greater or less speed, as may be required, and the cone pulleys usually employed for that purpose are dispensed with. When it is desired to stop the supply of ink without stopping the revolution of the machine, all that is requisite is to slide the pinion into a position between two of the circles or segments of teeth, and the revolution of the doctor roller is stopped immediately. Another improvement consists in having a rod constantly revolving in the ink so as to keep it in motion, and hence at an equable temperature in cold weather, thereby avoiding the necessity for the frequent application of heat thereto.—Patent abandoned.

1445 P. A. DE BERENGER. *Improvements in kilns for burning limestone.* Dated May 16, 1867

This invention consists in constructing the said kilns in the form of vertical chambers provided with gratings or bottoms, and arranged transversely in sets one above another in such manner as to admit of the lower ones being brought immediately over the furnace, by which the heat is caused to ascend through the lime placed within the said kilns for the purpose of being burnt, the said transverse sets being alternately supplied, discharged, and brought successively next in turn over the fire. An opening is left within the said column for the admission of air for regulating the draught, and in peeting materials under operation, as may be necessary.—Patent abandoned.

1446 C. ROBERT. *Improvements in breech-loading firearms.* Dated May 16, 1867.

The barrel of this firearm is at its breech fixed into the front end of a body of a trough-like form open at the top to allow room for the introduction of the cartridge in loading and for pushing it forward into the barrel. The trough-like space in the barrel is closed after the cartridge has been introduced by a block jointed at its fore end to the top of the body. The block has a central hole formed through it from end to end, and contains a needle or striker for exploding the cartridge by a blow on the centre of its base. The block also has on its under side a strong hook or projection through which descends, through a slot cut in the bottom of the trough, from part of the body, and it is locked by a sliding bolt working in guides on the under side of the body. This bolt receives its motion from a lever which, when the block is locked in position, fits close underneath the trigger guard; the lever works on a horizontal axis at its forward end, and has teeth upon it around the axis, and when the hinder end of the lever is thrust downwards and forwards, as in unlocking the block, or when the contrary movement is made, in locking the block, the teeth gear with rack teeth formed on the bolt. To lock the block the bolt enters into the hook upon it, and in unlocking the bolt is withdrawn, whilst at the same time another part in connection with the bolt comes against the back of the hook, and by pressing against it partly raises the block so that the hand may readily get hold of it to turn it back. On the joint of the block there is a spring catch like the spring of a pocket knife, and tending to bring the block to one or other of its extereme positions. The blow to fire the cartridge is struck by an internal hammer mounted on a spring arm which, when released, throws the hammer head forward, so as to cause it to impinge upon the instrument or striker within the block, and this striking the base of the cartridge fires it. The striker passes through a cavity containing grease, and is so kept lubricated. The spring arm of the hammer is forced back to prepare it to strike the blow by the action of the lever which locks and unlocks the breech block; when the lever is moved so as to unlock the breech block, a projection upon it comes against the spring arm of the hammer, and forces it back until it is caught and retained by a detent at the end of a short lever, and when the trigger is drawn back to fire the charge, it moves the short lever on its centre, and so sets the hammer free, and the tension of its spring arm causes it to fly forward and strike the blow which fires the charge. In order to prevent the arm from being discharged accidentally, the inventor employs a bolt or rod, by turning which the trigger can be prevented from releasing the catch or detent that holds back the striker.—Patent abandoned.

PROVISIONAL PROTECTIONS.

Dated September 11, 1867.

2573 W. Baird, Glasgow. An improved apparatus to be used for registering the number of passengers entering vehicles.

Dated September 25, 1867.

2698 J. Musgrave, Belfast. Improvements in stable, cow-house, and harness-room fittings, parts of which are also applicable for other purposes.

Dated November 2, 1867.

3087 H. W. Grylls, Dalston, civil engineer, H. Neville, Mile End, builder, and J. Holt, Hackney-road. Improved apparatus for obtaining and applying motive power.

Dated November 13, 1867.

3213 T. Taylor, Wellington-row, Bethnal-green. New or improved implements or apparatus for playing games of skill and chance.

Dated November 23, 1867.

3324 J. H. Johnson, Lincoln's Inn-fields. Improvements in breech-loading firearms, and in cartridges for the same. (A communication.)

Dated November 28, 1867.

3384 J. Rayls, Kinburn-cottage, Durdham Down, Bristol. An improved chemical preparation or compound to be used in preparing mixed textile fabrics for dyeing or colouring.

Dated November 29, 1867.

3386 T. B. Jordan, South Lambeth, mechanical engineer, and J. Darlington, Moorgate-street-chambers, City, mining engineer. Improvements in machinery for boring rocks, and in apparatus for driving, rock-boring, tunnelling, coal-cutting, and other machinery employed in mines, collieries, and quarries.

3394 A. Turner, Leicester, elastic fabric manufacturer, and W. E. Newton, Chancery-lane, civil engineer. Improvements in the manufacture of carpets and in warping and preparing warps for the same, and in the machinery or apparatus to be employed therefor.

Dated November 30, 1867.

3409 R. Clay, jun., Muswell-hill. Improvements in breech-loading firearms.

Dated December 2, 1867.

3414 G. Hetron, Leadenhall-street, City. An improved method of constructing a castor for containing pepper, salt, or other condiments for domestic use.

Dated December 3, 1867.

3436 W. Pidding, Beresford-street, Walworth. Improvements in placing, arranging, or fixing needles and threads and other like fibrous materials on to reels or receivers so as to render them more convenient for use, also in the manufacture and forms of such reels or receivers, and in the materials thereof.

Dated December 4, 1867.

3448 J. Newton, Globe Foundry, Leeds. Improvements in the means of and apparatus for lubricating certain parts of doffing-knife apparatus.

3453 E. Walker, Westmoreland-street, Pimlico. Improvements in the construction of breech-loading ordnance.

3455 J. T. Webster, Mansfield, Nottinghamshire, and W. Oxley, Manchester, mill furnisher. Improvements in machinery for spinning and doubling fibrous materials.

3457 W. A. Herring, Chertsey, engineer and ironfounder. Improvements in apparatus for warming buildings in which high-pressure steam-engines are employed.

Dated December 5, 1867.

3459 D. Smith, Bury, Lancashire. Improvements in steam boiler furnaces, and in apparatus connected therewith.

3461 J. Green, Lockwood, near Huddersfield, grocer. Improvements in machinery or apparatus for cutting or breaking sugar.

3462 J. Mahon, Newcastle-upon-Tyne. Improvements in bags for coffee and other such like cots.

3463 S. Perkins, engineer, and W. Smellie, forge manager, Gorton, near Manchester. Improvements in the manufacture of malleable metal of a steely quality, partly from Bessemer "scrap" or other Bessemer metal.

3464 J. G. Scott, Edinburgh. An improved means to be employed for effecting the safe transmission of money or money orders; also improvements in the formation of documents that have to be separated.

3467 M. Tildesley, manufacturer, and J. Bird, manager,

Digitized by Google

Willenhall, Staffordshire. Improvements in annealing furnaces, and in apparatus to be employed therein, parts of which improvements may be applied to certain other descriptions of furnaces and fires.

3469 P. G. L. G. Designolle, Rue de la Seine, and J. Casthelaz, Rue St. Croix de la Bretonnerie, chemists. Improvements in the manufacture of explosive and fulminating powders.

Dated December 6, 1867.

3473 J. Durrans, Thurlstone, near Penistone, Yorkshire. An improved material or composition to be employed for covering or coating the interior surfaces of moulds, crucibles, or ducts, previous to their receiving molten metal in the process of casting, and for other purposes.

3475 W. N. Nicholson, Trent Ironworks, Newark, Nottinghamshire, agricultural engineer. Improvements in machinery for spreading grasses, part of which improvements are also applicable to machines for cutting and collecting grasses or corn.

3477 F. Roper, Monson-street, Lincolnshire, machine maker. Improvements in apparatus for driving straw elevators.

3479 R. Jones and J. Abrahall, Birmingham, jewellers. Improvements in the manufacture of hollow metallic seamless spheres and ornaments.

Dated December 7, 1867.

3481 C. Brazil, Chorley, Lancashire, manufacturer. Improvements in machinery for sizing cotton and other yarns.

3483 R. B. Jones, Nelson-terrace, City-road, telegraphic engineer, and W. Powell, Circus-place, Finsbury, telegraph engineer and contractor. Improvements for the prevention of incrustation in steam boilers.

3485 O. Barrett and H. Leggott, Bradford. An improved knife cleaner.

3487 J. Partington, Astley, Lancashire. Certain improvements in the method of heating buildings, and in the apparatus connected therewith.

3489 W. Clissold, Dudbridge Works, near Stroud, Gloucestershire, engineer. Improved machinery for preparing fibrous substances for spinning.

3491 C. M. Barker, Kennington-park-road, engineer. Improvements in socket and flange spigot pipes.

3493 A. M. Clark, Chancery-lane. Improvements in orthopœdic apparatus for the prevention and treatment of spinal diseases. (A communication.)

Dated December 9, 1867.

3497 W. Clapperton, manager, Walkenshaw Foundry, Johnstone, Renfrewshire. Improvements in machinery for shaping cask headings and similar articles.

3499 L. Rose, Leith, lime and lemon juice merchant. An improved mode of preserving vegetable juices.

3501 H. Bessemer, Queen-street-place, Cannon-street, City. Improvements in the manufacture of fire-bricks, tiles, and solid or hollow fire-lumps, and in the manufacture of retorts, pipes, crucibles, or other hollow vessels or moulds required to resist a high degree of heat, and also in the manufacture of ornamental bricks, tiles, quarries, trusses, bosses, vases, busts, figures, columns, capitals, bases, cornices, copings, tablets, finials, and other articles of an ornamental character employed in building and in architectural decorations.

Dated December 10, 1867.

3503 C. Kerby, St. Dunstan's-hill, City. Improved apparatus for filtering liquids.

3504 R. G. Lowndes, bleacher and finisher, Auldhousefield and Crofthead, Renfrewshire. Improvements in finishing textile and other fabrics, and in the machinery or apparatus employed therefor.

3505 C. Connor, Old Ford, shoemaker. Improvements in umbrellas and parasols.

3506 W. H. Barlow, Old Palace Yard, Westminster. Improvements in apparatus for measuring approximately the quantities of earthwork in continuous cuttings or banks, such as are used in the formation of railways.

3507 W. Palliser, Major unattached, Army and Navy Club, Pall Mall. Improvements in ordnance and in projectiles used therewith, as also in the processes employed in their manufacture.

3508 W. B. Leachman, Leeds, engineer. An improved rotary water or steam motive power engine.

3509 J. Grout, ironmonger, and E. Mathews, agent, Hereford. Improvements in apparatus for training or growing hops and other plants, which improvements may also be applied to line posts and other posts or supports for various purposes.

3510 J. W. Burton, Leeds. Improvements in the treatment of fibrous materials, and in apparatus used therein.

Dated December 11, 1867.

3511 J. Woolfield, St. Peter's, St. Alban's, Hertfordshire. An improvement in machinery for corrugating sheets of metal.

3512 G. Holcroft and W. N. Dack, Manchester, engineers. Certain improvements in steam engines.

3513 H. Giles, New North-road. Improvements in the manufacture of hats and bonnets, and in the apparatus employed therein.

3514 W. J. Fraser, Commercial-road East, engineer. Improvements in tubular steam boilers.

3515 A. Camme, Boulevart de Strasbourg, civil engineer, and F. Delpech, Grande Rue Batignolles, Paris, engineer. Improvements in manufacturing iron and steel chains without welding.

3516 A. M. Clark, Chancery-lane. Improvements in presses for stamping or endorsing. (A communication.)

3517 A. M. Clark, Chancery-lane. An improved process for the reduction of tin, so as to render it applicable for coating metals and for other purposes. (A communication.)

3518 A. T. Carr, Winkleigh, Devonshire. An improved manure.

3519 J. M. Napier, York-road, Lambeth. Improvements in apparatus or appliances for serving mustard and other condiments.

3521 G. H. Nick, Passage Saulnier, Paris. An improved sheave or pulley for ships' blocks or other purposes.

3522 T. A. Weston, Birmingham, engineer. Improvements in saws. (A communication.)

Dated December 12, 1867.

3523 G. A. Young, Eagle-street, Red Lion-square, surveyor. An improved curtain or screen for separating the stage from the audience part in theatres and music halls, in order to prevent the spreading of fire, also applicable to other buildings where it is desired to prevent the spreading of fire from one part of the building to another part.

3524 J. Goodman, Loughborough, Leicestershire, coach builder. Improvements in the manufacture or production wheels used for carriages or other vehicles.

O. Butler, Kirkstall Forge Company, Leeds. Improvements in securing the tyres of railway engine and carriage wheels.

3526 J. R. Baillie, Rochefort-villas, Hoe-street, Walthamstow, Essex, naval architect. Improvements in caissons.

3527 J. Ward, Port Glasgow, Renfrewshire. Improvements in lamps to be used under water.

3528 R. Roberts and P. Williams, Pontypridd, Glamorganshire, engineers. An improved equilibrium slide valve for steam engines.

3529 R. W. Brownhill, Walsall, Staffordshire, manufacturer. Improvements in water tuyeres for blast furnaces, smiths' fires, and for other like purposes.

3531 E. Death, Leicester, engineer. Improvements in steam pumps.

3532 W. G. Hanning and G. B. Knott, Newcastle-upon-Tyne, and L. C. F. Clerc, St. Mary Axe, City. Improvements in lamps. (Partly a communication.)

3533 J. Collingham, worsted spinner, and T. E. Smith, machine maker, Keighley, Yorkshire. Improvements in spinning and twisting frames, known under the denomination of "cap frames" and "flyer frames."

3534 P. Bawden, Norland-square, Notting-hill, brick manufacturer. Improvements in machinery for the manufacture of bricks and tiles.

3535 E. R. Sintzenich, Duke-street, St. James's. Improvements in the treatment of paper and certain woven fabrics for rendering them ornamental and durable as articles of dress, and for decorative and ornental purposes.

3536 H. Field, Tulse-hill. Improvements in the manufacture of candles, and in the moulds or apparatus employed therein.

3538 R. Boby, Bury St. Edmunds, agricultural implement maker. Improvements in hay-making machines, horse hoes, horse rakes, and other analogous agricultural implements or machines.

3539 W. Richards, Birmingham. Improvements in firearms and cartridges.

3540 J. Robinson, Dalton, near Huddersfield. Improvements in the manufacture of mohair and similar fabrics.

3541 J. H. Pepper, Boundary-road, St. John's Wood, professor of chemistry, and T. W. Tobin, Old Jewry, City, architect. Improvements in apparatus used in producing scenic illusions.

Dated December 13, 1867.

3544 J. H. Johnson, Lincoln's Inn-fields. Improvements in the manufacture of artificial fuel. (A communication.)

3546 J. Williams, Great Saughall, Cheshire, schoolmaster. An abacus or apparatus for imparting instruction in arithmetic, and which apparatus may be advantageously employed in teaching reading.

3550 J. G. Settle, Horncastle, Lincolnshire. Improvements in door bolts and indicators.

3552 W. E. Newton, Chancery-lane, civil engineer. Improvements in bench planes and moulding tools. (A communication.)

Dated December 14, 1867.

3554 H. Atkinson, Wharf-road, City-road. Improvements in gas retort ovens and furnaces. (A communication.)

3558 W. and F. Bates, Sowerby-bridge, near Halifax, machine makers and millwrights. Improvements in washing machines known as "dollys," which improvements render such machines also applicable for crushing and fulling fabrics.

3560 R. Tinkler, Penrith, churn manufacturer. Improvements in churns.

3562 G. Clark, Arundel-street, Strand. Improvements in guns, projectiles, and cartridges, and in the construction of the same.

3564 T. C. Parson, jun., Bristol, surgeon dentist. Improvements in skates.

3566 A. M. Clark, Chancery-lane. Improvements in the extraction of ammonia from fermented and other liquids, and in the regeneration of the agents used in such extraction. (A communication.)

3568 E. Rimmel, Strand, perfumer. An improved construction of portable fountain.

3570 W. Conisbee, Herbert's-buildings, Waterloo-road. Improvements in cylindrical chromo-lithographic and typographic printing machines.

Dated December 16, 1867.

3574 J. Dawson, Greenock, engineer and sugar refiner. Improvements in treating sugar syrups.

3576 G. D. Kittoe, Clerkenwell, engineer. Improvements in engines actuated by air, steam, or other fluids.

Dated December 17, 1867.

3582 N. Haley and J. Hodgson, Bradford, machine makers. Improvements in machinery for twisting or doubling wool, silk, cotton, or other fibrous substances, part of which is also applicable to machinery for spinning such substances.

3384 A. Shrimpton, Redditch, Worcestershire, fishhook manufacturer. Improvements in papering needles or making up packets of needles for sale.

3586 W. Ross, Grove-street, and A. Long, Aylesbury-terrace, Walworth. Improvements in means for preventing and removing incrustation in steam boilers.

3588 S. Marsters, Lynn, Norfolk. A new or improved machine for rubbing, washing, and sizing ropes, cords, or twines.

3590 W. A. Gilbee, South-street, Finsbury. Improvements in the method of and apparatus for raising water. (A communication.)

Dated December 18, 1867.

3592 H. Green, Preston, gas engineer. Improvements in furnaces for steam boilers and other purposes.

3594 R. D. Dwyer, Liverpool. Improvements applicable to metallic bedsteads and mattresses.

3596 J. Murray, Whitehall-place. Improvements in the construction of roads or streets.

3604 H. H. Murdoch, Staple Inn. Improvements in means or apparatus for propelling canal boats and other vessels, parts of which improvements are applicable to other purposes. (A communication.)

Dated December 19, 1867.

3606 G. H. Ellis, Outram-road, Addiscombe, Surrey, engineer. Improvements in apparatus for cleaning boots and shoes.

3610 J. Atkins, Birmingham, merchant and manufacturer. Improvements in metallic bedsteads, cots, and couches.

3612 A. Cochran, Kirtonfield, Renfrewshire, bleacher and dyer. Improvements in machinery for finishing woven fabrics.

3614 W. H Richardson, Glasgow. An improved apparatus to be employed in the manufacture of iron and steel.

3616 J. Kerr, King William-street, City, gun maker. Improvements in breech-loading firearms

3618 W. B. Pullar, Bread-street, City. Improvements in the manufacture of fabrics to be made into skirts.

3620 B. Monson, Colchester. Improved apparatus for sliding the sash frames of windows, and for sliding shutters.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated December 18, 1867.

3602 M. H. Collins, Mass., U.S. An improved lamp.

Dated December 20, 1867.

3624 L. L. Tower, Mass., U.S. Having reference to faucets and vessels for measuring liquids. (A communication.)

Dated December 21, 1867.

3626 J. T. Kershaw, surveyor, St. Paul's-road, Islington. An improved ventilator.

Dated December 23, 1867.

3645 W. Walker, Liverpool, consulting engineer. Improvements in cotton ties. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," December 24, 1867.

2063 T. Berney. Bending bars.
2297 C. Hohgrefe. Chimney tops.
2307 F. H. Holmes. Electric light.
2308 C. D. Abel. Removing sulphur. (A communication.)
2314 A. M'Dougall. Separation of sulphur from sulphuretted hydrogen.
2322 J. J. Bright. Actuating propellers.
2323 G. and J. Pilling and F. Jennings. Covering the edges of fabrics.
2327 A. Swan. Recovering lees.
2331 J. Fawcett. Extracting oils.
2332 T. Walker. Cutting grooves.
2334 W. B. Leachman and J. Holroyd. Pumping fluids.
2335 A. M. Clark. Securing bayonets. (A communication.)
2339 W. Betts. Metallic capsules.
2340 W. Betts. Metallic capsules.
2341 G. Buxton and S. Bann. Axles.
2344 J. T. Way. Treating phosphate of lime.
2354 G. Clarke. Fire-escapes.
2355 J. Day and W. Dorber. Carriages.
2360 J. W. Dudley. Cutting corks.
2362 A. Leveson. Coverings for perambulators.
2371 C. E. Brooman. Ornamenting fabrics. (A communication.)
2388 A. Cohen. Watches. (A communication.)
2389 J. Murgatroyd. Steam boilers.
2391 C. E. Hall. Hoeing turnips.
2394 G. Luvekx. Waterproof tubes.
2405 R. King, J. Lowden, W. Gartside. Carding engines.
2412 T. W. Lawson. Ships.
2422 J. Varley. Measuring water to steam boilers.
2433 F. J. Cleaver. Screw presses.
2436 E. Sonstadt. Treatment of sea-weed.
2455 W. B. Smith. Lever watch movements.
2460 A. Stewart. Textile fabrics.
2477 W. J. Matthews. Breech-loading firearms.
2507 J. Howard and E. T. Bousfield. Cutting grass.
2508 G. A. Buchholz. Hulling wheat.
2594 R. Lowe and J. Taylor. Jewellery.
2604 J. Jeyes. Substitute for oiled silk bladders.
2626 J. Soames. Candle fixer.
2691 P. H. Colomb and F. J. Bolton. Production of light.
3031 W. E. de Bourran. Concentrating saccharine fluids.
3093 J. Orr. Plaiting woven fabrics.
3110 H. Allman and F. N. Gisborne. Lamps.
3248 I. Swindells. Separating minerals.
3277 W. Anderson. Evaporating apparatus.
3319 W. Boulton. Transmitting motive power.
3361 J. S. Smith. Ventilating buildings.
3410 J. Fitter. Expanding tables.
3437 J. Thorpe. Waterproof paper.
3440 J. Gjers. Cast steel.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

3119 F. A. Chevallier
3150 J. Butchart, S. A. Morrison, and H. Stroud
3171 J. Ramsbottom and T. Blackburn
3174 W. Reid
3175 J. H. Johnson
3176 J. Hargreaves
3191 J. Paterson
3195 R. A. Brooman
3236 T. R. Harding
3250 T. Bouch

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 10, 1868.

TORPEDO EXPERIMENTS.

WE have from time to time said enough upon this question to render it unnecessary now to remark how very important an arm we consider it to be for naval warfare. In view of this importance, we are glad to see that our authorities are not losing sight of the question, although they are not proceeding so vigorously to develope a perfect torpedo as we could wish to see them. There would be no difficulty whatever about this if they would only accept the suggestion made by us some time since that they should try Captain Harvey's torpedoes. From an examination of these agents of destruction, we assert that they are the most judiciously constructed and effective ever planned,* and ought to have the serious attention of Government. Recent experiments have, however, taken place in this direction, both in England and on the Continent. Those at home were made at the close of the past year at Portsmouth, the object being to prove the effects that would be produced on a steam launch by firing a submerged torpedo containing a charge of 100lb. of gunpowder, when suspended from the end of a spar projecting over the bows of the launch, and supposed to be in contact with the bottom of an enemy's vessel or a marine obstruction of any kind. The torpedo was fired by one of the "Excellent's" boat batteries, the construction and manipulation of which is now taught to all seamen gunners passing through the ship as part of their ordinary drill. The spar, with the torpedo attached to its outer end, was slung and fitted with a running rope fall in the same manner as was applied, or nearly so, in the first experiment of the kind when the captain's gig of the "Excellent" was converted into a temporary torpedo boat. The torpedo was exploded at the desired moment, throwing up an immense mushroom-shaped column of water, while the only effects felt by the steam launch from the explosion was the taking in of a quantity of water over the bows. This was of no moment, however, as endangering the floating power of the boat; but even its entrance could have been prevented, by simply covering in the boat forward with canvas, as is done with gigs and other small boats in all experiments of the kind made with them. So far, then, the experiment proved successful, but it is not a new idea, and moreover is not exactly the kind of experiment we would wish to see carried out. Instead of a torpedo with a charge of 100lb. of gunpowder, let us have a fair trial of one charged with a mere modicum of Horsley's powder, as Captain Harvey proposes, and then let us see where the vessel opposed to its action will be.

But they are carrying out the investigations into the torpedo question in a better manner in France, and they seem to be nearer a solution of the problem than we are. We hear that at Brest some extraordinary effects were lately produced by a new kind of torpedo tried in the River Landerneau, which flows into the bay. The vessel selected for destruction was an old ship, the "Wagram," of 100 guns, the first tier of which had been cut down. The new torpedo appears to be far superior to either the English or American and Russian one. The former is only efficacious when the vessel is passing over it; the latter are so contrived as to stick to the vessel and cause a shock. But the new French torpedo produced its effect at a distance of 12 metres from the hull and six metres below water. There were four torpedoes thus placed around the vessel, and connected by wires with an electric battery on shore. On the signals being given, three immense sheaves of water were seen rising to the height of a sixth storey; the wire of the fourth torpedo being broken, it did not go off. Nevertheless, the ribs and planks of the vessel were shivered, and there was barely time to run the vessel on shore. The effects approach those which would result from the use of Horsley's powder, but the absence of any details prevents us discussing the matter further. It is clear, however, that such torpedoes as Captain Harvey's and the above will, with judicious arrangement, prove invaluable for the protection of ports in time of war.

Having referred to Captain Harvey's torpedo, it may be well to state that that officer is still endeavouring to convince our Government, through the Obstruction Committee (rightly so named), of the efficiency of his torpedo. We hope he may succeed, but fear it will require a little of Horsley's powder to force home to their convictions the fact that in this torpedo we have the best known practicable means of destroying vessels at sea without coming into collision. Although Horsley's powder, the explosive used by Captain Harvey, is exceedingly powerful and rapid in its action, it is perfectly under control. This is evidenced by some experiments which were recently made in a cutting for a tunnel at Milford between nitro-glycerine and the explosive powder which is manufactured, without danger of decomposition or spontaneous explosion, by Mr. Horsley. The preference was given to the powder, not only for its power when exploded in a particular kind of cylinder, but also for its economy, and its greater safety in use and storage. With this desirable agent at command we urge upon the Admiralty the importance of testing the merits of Captain Harvey's torpedo. If it be a failure a very few pounds will prove it such. If it be the success we believe it to be, then thousands will be saved to the country in useless experiments in other directions.

* For particulars of Captain Harvey's torpedo see MECHANICS' MAGAZINE for March 29, 1867, page 189.

ELECTRICITY AND TELEGRAPHY—ITS PAST AND FUTURE.

IN reviewing the progress made during the past year in electricity and telegraphy, we pause at the outset to dwell for a short time on the great loss the scientific, but more particularly the electric, world has sustained. One of the greatest ornaments to science has passed away from amongst us. Michael Faraday is dead. We published soon after that melancholy event a short memoir of him, but in reviewing the electrical facts of the year we cannot but allude to him who for so long a period has been so intimately associated with the science. Who that has listened to him, as he lectured at the Royal Institution to crowded and delighted audiences for so long a time, can ever forget the man, possessed as he was with that rare power of conveying thoroughly, and in so easy a manner, the facts and theories he himself was so conversant with. To him more than to any one, and to his many and important discoveries, the present advancement of electric science, and consequently, we may add, telegraphy, is mainly due, and though the man may have passed away, yet the name will live so long as electricity is studied and the world lasts. His numerous discoveries and researches were reprinted some years ago from the "Philosophical Magazine," where they were originally published, as from time to time the experiments were made. This edition is now very rare, and is much sought after. We trust before long to see a reprint of the labour of a life devoted to the elucidation of electricity. During the late years of his life he was unable to bring his faculties to bear upon science, and he died honoured by his Queen and his country.

Passing on to the progress made in the various branches of this science, we will first allude to the machine of Mr. Wilde, of Manchester, which created so much excitement at the Royal Society's soirée. The invention itself is one of the facts of the preceding year, and, as such, was alluded to by us in our annual summary; but as no description of it had appeared, and its début before the public did not take place until early last year, we mention it prominently here. As a description with drawings and full details appeared lately in our columns, we will only briefly allude to it. The induced current obtained from a small magneto-electric machine is used to excite a large electro-magnetic machine, and the current induced from the latter is applied for the purpose of experiment. The armatures in both machines are those known as Siemens', their peculiarity being that the wire is wound longitudinally round the armature. These armatures are driven at a high velocity by a small steam-engine, or by manual labour. The electricity induced from the larger machine is of a power far exceeding anything hitherto obtained; and the results shown in fusing large wire, and the incandescence of charcoal, are astounding. But it must be remarked that these results were obtained at the expense of great mechanical force. At a subsequent soirée of the Royal Society, Professor Wheatstone and Mr. Siemens exhibited machines similar in construction to that of Mr. Wilde, but differing materially in the manner of excitation. Those gentlemen pursued their investigations independently of each other, and, strange to say, almost simultaneously arrived at similar conclusions. Instead of using an independent machine to excite the larger, they found that the machine once excited, the residuary magnetism by its action was sufficient to induce a weak current in the armature, this current, owing to the wires of the armature being in connection with those of the electro-magnet, excited it further, which, of course, acted again upon the armature, producing a more powerful current. This action and reaction continued until a maximum current of enormous power was induced. The time required to arrive at this maximum was but small. It was found only necessary to excite the electro-magnet in the first place with a single cell, after that there would be always sufficient residuary magnetism to set the machine in action. More powerful results were obtained by Professor Wheatstone, by the insertion of a shunt in the circuit between the armature and the electro-magnet. Mr. Ladd subsequently made an alteration in Wilde's machine; instead of the horse-shoe form of electro-magnet, he made his with two bar magnets, with a Siemens armature at each end, the one being used to re-act on the electro-magnet, and the other for applying the induced electricity to experimental purposes. The electricity obtained from these machines is of enormous power, and will be of great advantage for lectures, where a large amount can always be obtained readily. The only practical purposes to which this invention has at present been applied are those by Mr. Siemens, who uses his large machine for magnetizing large bars, &c., and a small machine, similar in principle, for blasting purposes. This latter is a very pretty instrument, to which we hope shortly to call the attention of our readers.

Magnesium has been tried as a positive element and has given very satisfactory results; in some experiments made, it was proved that this metal used with water was equal to a similar amount of zinc in acidulated water. We are waiting further experiments with this metal before we can fairly judge of its practical advantages.

Some highly interesting experiments were made by showing the mechanical action in voltaic circuits. Results were obtained by currents from a Ruhmkorff coil, as well as

Digitized by Google

rom an ordinary battery. A similar result is also mentioned by De la Rive, in a paper that appeared during the year on "Stratified Discharge in Vacuo." This paper contained many interesting experiments, and adds many facts to the elucidation of Grove and Gassiot, on discharges in vacuo. Some experiments have since been made which prove that no discharge takes place in a perfect vacuum. A valuable machine was exhibited at the Royal Society for the production of ozone, by induced currents, obtained from a powerful Ruhmkorff coil, passed over a series of condensers.

We mentioned in our last summary that the Government had the question of telegraphs before them with the view of obtaining the control of the various telegraph lines throughout the country, and placing them under one system in the hands of the Post Office administration. Since then the matter has been constantly before them, and it is now decided that such shall be carried out, and sufficient inquiries have been made, and the matter has been so far advanced that the Government has given a notice of their intention to bring in next session a most comprehensive bill, with the view of obtaining the sole control of our entire system.

A bill was brought into Parliament by Mr. H. B. Sheridan, passed the Commons, and withdrawn after Committee in the Lords, for establishing a system of communication between passengers and guards of trains in motion. At the Committee, railway managers and the inventors of the various systems now in use were examined, and it was decided that further experiments be made. Since our last notice, trains fitted with electric passenger communication have been constantly running—on the South-Western on Mr. Preece's plan, on the South-Eastern on Mr. Walker's; and trains have also been fitted with Mr. Martin's plan on the North-Western. These different plans are to be again tested on various lines, and it is most probable that if the reports are in any way satisfactory, further action must be taken in the matter.

Great activity has been shown in the India Telegraph Department during the past year, and steps taken to improve in every way the working of the system out in India. New poles and insulators have been sent out in quantities, and we are happy to find that progress is really the order of the day. Appointments were hitherto made in a somewhat reckless manner, and anyone joining in India, with a superior knowledge to those already engaged, found the groove too deep to get out of, and was simply compelled to follow the old track. Now the appointments are filled up by persons somewhat qualified by previous instruction in electricity and practical telegraphy, who, after satisfactory examination, are sent out to India. In addition to this, some special instructors are being sent out with the view of imparting a knowledge of testing throughout the staff, so that the Indian telegraphist may now know where a fault is to be found; but it is a pity to stop here. Undoubtedly such instruction is very material, but what is most needed is a thorough instruction in constructing lines, in order that the faults might not be produced. Prevention is certainly better than cure; and although we believe that the knowledge of how to locate and cure a fault is most essential, yet we cannot but give the greater importance to that of prevention, by establishing such a thorough system of construction as would render the recurrence of faults but rare. The great energy that has been shown in this department of late has been due to the presence in England of the Director-General Colonel Robinson, R.E., who on lately assuming the reins, has been most active and energetic in introducing as many improvements as possible in order to bring the standard of the Indian system more on a par with that of the mother country.

The Paris Exhibition brought together a large collection of electric and telegraphic apparatus, but there was but little to attract any very especial attention. Since the previous Exhibition a steady improvement might be observed in the manufacture of the instruments; and with regard to speaking instruments, a large increase was noticed in the number of recorders, as compared with ordinary sight and sound instruments. The almost entire absence of submarine cables of our manufacture was greatly to be wondered at, Mr. Henley being about the only one who exhibited. Mr. Hooper exhibited some specimens of his manner of insulating with india-rubber, and obtained a gold medal.

The system of weather signals, as adopted by the late Admiral Fitzroy, and of prognostication and warnings being telegraphed from the central office, has been for some time abandoned, but at the time a great deal of good was derived from it. An agitation has been going on during the past year relative to it, and we shall again see before long the resuscitation of the signals, which, at seaports, will again, as formerly, be a boon to the whole seafaring class.

In Submarine Telegraphy extension is gradually but surely going on. Although many breakages and repairs have taken place, we are happy not to be able to chronicle the decease of any member of this important family. The Atlantic Cable of 1866 has suffered from breakage twice, once close to the shore at Heart's Content, the second time at some little distance at sea, where the cable crossed a shallow patch. In both cases the damage was stated to have been done by icebergs, and the necessary repairs quickly executed. The Malta and Alexandria Cable has been periodically troubled, but the precaution of having a repairing ship on the station has prevented the interruption from being of long duration.

A small length of cable, thirty-five miles, was laid from Ceylon in 1866, but notice did not arrive until after our summary. This cable is remarkable for the excellence of its core, which consists of Hooper's Insulator. The resistance of the insulating medium is stated at 7,000 million ohms per knot, exceeding any core yet produced.

The New Zealand Cable, from Lyall Bay to Disaster Point, a distance of forty-two miles, was laid in 1866, but as the news did not appear in our last summary we mention it now. This was a large cable of one wire, manufactured by Mr. Henley, and weighed over nine tons per mile. It was protected externally by a coating of asphalte compound. Mr. Henley also manufactured and laid a large cable from South Foreland to La Panne, a distance of forty-seven miles. The main cable weighed nearly ten tons; the shore ends of ten miles, nearly twelve tons per knot, contained four conducting wires, and had an exterior protection of asphalte compound.

The Telegraph Construction and Maintenance Company manufactured and laid cables from Placentia Bay (Newfoundland) to St. Pierre, and from St. Pierre to Sidney, a distance of 300 miles. The cable consisted of one conducting wire, protected by external iron wires weighing 2¼ tons. From the excessive coldness of the water where this cable is submerged, the insulation test is very high, being over 4,000 million ohms per knot.

The past year has seen the advent of a new cable manufacturing company, the India-Rubber, Gutta-Percha, and Telegraph Works Company at Silvertown having erected some excellent machinery, manufactured and laid a cable from Cuba to Key West, and from there up the Florida coast. The cable was 245 miles in length, consisted of one conducting wire, protected in the ordinary manner by external wires. The insulation was higher than anything previously manufactured. We are glad to see that they have taken up this branch of manufacture, for it is only at their works that one can have a cable manufactured in its entirety. The conducting wire is covered with the insulator, served, and finally protected with the external wires, all on the same premises.

Of Cable Expeditions, the Cuban has proved as yet the most melancholy that ever left our shores. The ship arrived out there in the height of summer time, the most unhealthy season of the year; before the completion of the work yellow fever appeared on board, sparing but few, and almost disabling the ship; when the fever finally disappeared, fourteen of the staff had fallen victims to this fearful scourge. Amongst the number, we regret to find the names of Mr. W. E. M. Medley and Mr. Phillip Crookes, two most promising young electricians.

A short length of heavy cable, protected by asphalte compound, for insertion in the Portpatrick cable, has been also lately manufactured at the Silvertown works.

Railway Telegraphs appear to be on the increase, the block system of signalling coming more and more into favour. We notice with pleasure its extension on the various lines, but still trust to see its adoption more general. A new repeating signal apparatus, the joint invention of Messrs. Preece and Warwick, exhibited at the soirées of the Royal Society, and of the Institution of Civil Engineers, has been adopted and used largely on the Midland and South-Western Railways. It is intended for signal boxes, where the distant signals are so situated as to be out of sight of the signalman. The apparatus consists of a small indicator surmounted by a miniature semaphore, the state of the distant signal being always indicated by the position of the arm of the semaphore, and the condition of the light, whether in or out, by the tell-tale indicator. It is a very pretty and most useful apparatus, and one well worthy of adoption. We intend shortly to describe it, with illustrations.

The literature of the telegraphic year has not been very prolific. Amongst our books we can only find two—the "Electric Telegraph," by Robert Sabine; and a new edition of the "Handbook of Practical Telegraphy," by R. S. Culley. The latter is an invaluable book, and one that no practical telegraphist should be without. Several brochures have appeared on the question of Government and the telegraphs, and a fair proportion of new and interesting matter has appeared in the scientific periodicals.

In looking forward to the prospects of telegraphy in the year before us we must first admit that the present stagnant state of things has affected telegraphic enterprise, which, for lack of capital, is at a standstill, but we hope that with the coming of spring we shall be able to welcome a return of confidence, and consequently of telegraphic extension. Good and useful schemes are ripe, and only await that return of confidence to be brought forward. The extension to India *viâ* the Red Sea and Bombay will we trust be again brought forward, and enable us shortly to bring our Indian possessions within easy certain telegraphic distance. The extension of the telegraph from Cuba to Jamaica and Panama may be confidently looked forward to as one of the enterprises of the year. The late successful completion of the Florida and Cuba Cable has made this extension a necessity, the carrying out of which again will lead enterprise on to the South American continent, and bring us within easy communication of many important points. The concession lately granted by the French Government for a new American route makes us look forward with anticipation to a Franco-American line, enabling us to communicate with our transatlantic friends on cheap terms.

In the course of the year we shall probably see the transfer take place of the various private systems of telegraph throughout the country to our Government, and

Digitized by Google

placed under the administration of the Post-office, a result that must in the end, under good and skilful management, tend to the advantage of the public by increasing the facility of telegraphing, and by greatly reducing the rates. We look forward to the day when telegraphy will be employed as much as the postal system is at present. In glancing back upon the progress made during the past year we cannot be unmindful that the great work is slowly and steadily advancing. Our knowledge of the hidden mysteries of the science daily become greater, and the practical applications of electricity are becoming more and more general, and we feel with confidence that the year before us will not close without some special developments in this mysterious but beautiful science.

RAILWAY REFORM.

OWING to causes into which it is unnecessary here to enter, our railways have, during the past year, attained a most unenviable notoriety. The financial condition of many of them is at the present moment truly pitiable, whilst the whole system is in a most questionable position. Had it not been for Government intervention during the year just closed some lines would doubtless have yielded to the pressure under which they laboured. How much longer some few others will be able to hold their own it is impossible to say. In fact, the commercial attitude of numerous lines just now is by no means calculated to inspire confidence in this class of securities, nor to encourage the development of the railway system in quarters still open to the improvement it ever carries with t. Of course we shall be told that railway depreciation and derangement is only part and parcel of the universal commercial convulsion which the past two years have witnessed. This is admitted; but it forms no excuse for railway defection which might have been materially lessened, if not altogether avoided, by stricter economy in outlay, and closer attention to the working details of the system. Now, it is by no means our intention to pour out lamentations for the past, nor to hurl invectives at the heads of railway directors or managers. Such a course would neither be of practical value nor lead to any good result. Seeing the present condition of matters, our purpose is rather to point out a remedy than to visit the shortcomings of officials with meaningless condemnation—for meaningless it would be just now. And in touching upon the matter at all we do not pretend to have discovered a perfect remedy for the general disorganized condition of railways. There are many departments in which reform is required that do not fall within our province to discuss. But there is one department—and that a most important one—which does peculiarly belong to us to consider, and which we hope to show may be materially benefited by a thorough reform, and this is the locomotive department. Of course, reform here would have a direct bearing upon the health of the whole system which it would unquestionably benefit in a greater or less degree.

One of the leading causes of railway depreciation is that heavy item of expenditure—maintenance of way and rolling stock. This item stands out with unpleasant prominence in every railway account, and although the means by which it might be reduced are, and have been for long past, really within reach, there is no sign of decrease, but rather the reverse. And it comes about in a very simple way; trains are run at excessive speeds with engines unnecessarily heavy for the work they have to perform. Of course we must have high speeds for some purposes; we need not knock off our express trains, but they can be drawn by engines of lighter build than we are now using, and fifty or sixty miles an hour will be as readily attained. The destruction to rails and rolling stock is as the square of the velocity, and this destruction, the bugbear of all railway accounts, would be greatly reduced by the use of lighter engines, that is of engines in which wheels are not overweighted. If instead of placing from six to seven tons on each wheel, as is at present done, not more than from three to four tons were brought to bear upon them, a great economy would be the result. Speeds should be regulated, and passengers charged according to the speed at which they travelled. With goods trains an uniform speed of fifteen miles per hour might be maintained. This is about half the present rate of speed at which these trains travel, but the compensation appears to us to lie in doubling the power of the engine, and giving them the same work to do in the same time at half the present speed. To prove that this could be done, let us suppose a thousand tons of goods requiring conveyance daily between two given points. Now, if instead of sending these in batches of 250 tons each by four trains, at the rate of thirty miles an hour, we made only two batches of them, and despatched them by two trains at fifteen miles an hour, we should effect an enormous saving. Precisely the same amount of work would be accomplished in the same period, with just half the number of trains. We should thus arrive at a reduction of risk of accident—and we all know what a fruitful source of accident goods trains are—and we should get besides fifty per cent reduction in the cost of haulage per ton of merchandize, to say nothing of doubling the carrying capacity of the railway itself.

We have so far indicated the theory of railway reform in one important department; its practice, it must be admitted, is another matter. But we are quite prepared to prove that the course we have pointed out is not only perfectly practicable but easy of accomplishment. This is by no means the first time we have discussed the question of railway reform; we have before debated the point upon exactly the same grounds over which we are now going. Nearly three years since in an article upon Locomotive Reform* we pointed out the great economy which would result from the use of engines constructed upon the very practical plan designed by Mr. R. F. Fairlie, C.E. Since we wrote, these engines have made substantial practical progress, some being in use on several lines of railway at the present time. Those of our readers who wish to investigate the details of Mr. Fairlie's engines are referred to the number of the Magazine quoted at foot. It will be sufficient here to notice the general principle of the system. The boiler is of greater length than in the ordinary locomotive, and is divided in the centre by the fire-box. Each end of the boiler terminates in a combustion chamber. Thus there are double sets of tubes running in opposite directions from the fire-box. There is also an upper series of tubes running from the tube plate in the combustion chamber to a smoke chamber placed inside the fire-box shell over the fire-box. The heat and products from the fire-box pass through the lower series of tubes to the combustion chamber, returning thence through the upper series to the smoke chamber, and passing out from thence through the chimney, which is over the fire-box shell. There is a division plate each side between the fire-box and shell in the water space, reaching up to 9in. above the ordinary water level, so that on going up steep gradients the tubes are not uncovered at either end.

The advantages arising from this system of construction are numerous and important. We have first a greater generating and maintaining power than can by any possibility be obtained by the ordinary system. In the next place, the whole weight of the engine, including fuel and water, is made available on the rails for traction power. Tenders are entirely dispensed with, and thus an unremunerative and costly incumbrance is got rid of. The boiler being carried on the centres of two distinct frames, each having its engines, wheels, and gearing complete, made on the bogie principle, distributes the weight over the number of wheels, say four or six in each frame. These being driven by their own engines act separately and independently of each other, although forming but one whole. The general arrangement of the engine enables it to pass round any curves, down to a radius of one and a half chains, with the greatest facility, the friction being reduced to a minimum. Turn-tables are not required for these engines, as they will run either end on. Thus upon all points this system presents important advantages, and if railway companies would only avail themselves of them a little more generally they would unquestionably find it greatly to their own interests and to those of the unfortunate shareholders.

Perhaps the most valuable testimony we can adduce upon the merits of the Fairlie system is contained in the report of Captain Tyler, the Government Inspector of Railways. The captain has just returned from an examination of the condition and prospects of the Grand Trunk Railway of Canada, and in his able report we find him stating that the engines which find most favour in Canada, and generally in America, are constructed with a four-wheeled bogie-truck under their leading and four-coupled wheels under their trailing ends. And engines of this description are now being built, to weigh about thirty-two Canadian tons, for future use on the Grand Trunk Railway. The tenders run upon two bogie-trucks. Six-wheeled coupled engines, such as are used in this country, are apt to leave the rails on an uneven or frozen road, and it is not safe to use them in Canada. This disadvantage of the existing pattern of the engine is, that neither the four wheels of the bogie-truck, nor the eight wheels of the tender, are available for adhesion; and that, in order to obtain sufficient adhesion for heavy loads in slippery weather, a considerable weight is required upon the four driving wheels. Referring to the durability of the rails, Captain Tyler observes that it is very important to keep the weights on the wheels as light as possible, especially in cold climates, and in pointing out the means of attaining this object he says:—"The class of engine best suited to the climate, and for the various circumstances of the case, would, I have no doubt, be an engine running on two bogie-trucks, each provided with a pair of cylinders, and four-wheeled or six-wheeled according to the work required—and without a tender. Such an engine would be peculiarly safe to travel over a winter road; would combine a minimum wear and tear to itself and the rails, with a maximum of adhesion, and would be the most effective and the most economical that the company could employ. I had the opportunity some time ago of testing engines of this description on the Neath and Brecon Railway, designed by Mr. Fairlie, and have found the principle to be good, though certain points of detail require improvement. Such engines are also in use for the sharp curves and steep gradients of the Queensland Railway." The points of detail referred to by Captain Tyler have been improved upon, and the principle is now as perfect as the present state of engineering science can render it. Seeing, then, that we possess, ready to hand, the means of effecting important improvements in our locomotive system, which would not only materially reduce the cost of rolling stock, but of maintenance of way, we urge upon railway officials and others interested to lose no time in adopting these means of special economy. The question is attracting much attention at the present time, and in another column we give an exceedingly well-written article upon the subject from a daily

* MECHANICS' MAGAZINE, February 3, 1865.

Digitized by Google

contemporary. By all means let there be unity of action in pointing out the evil, and let each do his best in his special department to aid in solving the important question of Railway Reform.

ELECTROPLASTIC.

UNDER this title the art of depositing metals in moulds is generally known on the continent of Europe, while in England it has been known by the name of electro-typing; but probably the best name for it is electro-casting, in contradistinction to pyro-casting, or casting by heat, as in ordinary foundries. The first idea of this art was suggested to Mr. Daniel on the invention of the galvanic battery which bears his name. M. Jacobi took up the suggestion, and produced some small castings of seals and other small objects; the process being so simple it was extensively practised by amateurs as an amusement. These castings were all on pure copper, as other metals were found too difficult or too expensive for the process; indeed, even yet when the process has been introduced into the fine arts, copper still is the metal that is mainly used.

The only other metals that have been electro-cast are silver and gold, but these to a very limited extent. The process of electro-casting in silver is a very slow process as compared with that of copper, notwithstanding that the equivalent of silver is nearly twice that of copper, and the electro-conductivity of silver is also greater. The difference in the rapidity of deposition in favour of copper is owing no doubt to the difference in electro-conductivity of the solutions in which they are dissolved, sulphuric acid and water, in which copper is usually dissolved, being a much better conductor of electricity than cyanide of potassium and water, in which silver is usually dissolved. This is very evident when the same solution is used for both metals; the deposition of copper then is not half that of silver with the same current of electricity. Gold can be electro-cast more rapidly than silver, cyanide of potassium dissolved in water being used as the solution, which might have been expected, as its equivalent is greater than that of silver. Hitherto, these three—copper, silver, and gold—have been the only metals that have been successfully electro-cast. It has often been attempted to deposit some white alloy which might serve as a base for electro-silvering, but hitherto without success. Ordinary German silver has been deposited, but the process is so slow, and, moreover, a considerable heat has to be maintained, so that for more than a simple coating it has not been successfully used. A white alloy for the above purpose is still a desideratum. From experiments that have been made, there appears no doubt that this desideratum will be supplied before long, but it will not be of the precise composition of ordinary German silver, but tin will take the place of nickel. There seems to be no doubt that pure tin could be electro-cast if we could make those solutions which give a reguline deposit conduct electricity more freely. We have seen some experiments made in this direction also, wherein there is every probability of success. At present, many articles are electro-cast in copper which are intended to be electro-silvered, such as jewel-cases, work-boxes, tea-caddies, ink-trays, &c.; in fact, all such articles as are highly enriched by sculptured ornamentation and electro-silvered, this process being much cheaper than pyro-cast German silver, as all such castings require the use of the chisel and graving tool besides smoothing and polishing, which electro-castings do not. There is no metal that will pay for pyro-casting and finishing but silver or gold, and even these, if done in quantities, are much more cheaply done by the process of electro-casting.

In the process of electro-casting copper there is nothing to be desired. It is very simple, and easily managed; in fact, when once fairly started, it will almost work of itself, and is less expensive than any alloy can possibly be, but the drawback exists in the metal itself in it being so readily oxidized. Not that there is any difficulty in silvering it—that is now easily enough done, but it is after the article is silvered that the defect of this metal appears. Unless the coating of silver is very thick it is soon cleaned off, or if by accident it should receive a blow on any salient part, the silver might be taken off, and the red copper would appear, which would soon turn to green and black by contact with the atmosphere. But ordinary German silver is subject to a similar objection; even common plated spoons and forks of this metal soon become very unsightly, and not only so but even poisonous, if great care be not taken so that a white alloy containing but a small proportion of copper would be a great acquisition for all electro-plate goods, but more especially for electro-casting in the finer branches of the art.

PHOTOGRAPHY.

PERMANENT PHOTOGRAPHS — PROTECTING SILVER PRINTS—IMPROVED METHOD OF PRINTING.

THE falling off in commercial prosperity in England is felt by photographers as severely as by others, but has had the good effect of drawing attention to those defects in ordinary portraiture which tend in some degree to add to the prevailing photographic depression. The photographs which now fill the windows of so many shops in our leading thoroughfares are historically worthless, for there is very strong evidence that they will all fade, though a small minority of them, which have been produced by good manipulations, founded upon the best principles of photographic chemistry, have a greater degree of permanence. Swan's carbon process gives capital pictures, infinitely more permanent than the ordinary silver print, yet commercially this process makes little headway against its silver rival, because the difficulties and expenses incidental to its adoption are barriers. The inventor of the process turns out carbon pictures regularly, but he charges more for carbon printing than his host of competitors do for the silver printing of pictures the same size.

Accordingly, at the late meetings of the London and Provincial Photographic Societies, the discussions relating to the fading of photographs scarcely ever include the suggestion that carbon prints shall be substituted for the present kind of pictures. Much time has been spent, and many experiments have been made, with a view to find some transparent substance with which to coat the present silver pictures, thereby protecting them more effectually from atmospheric influences, and rendering them more durable. Mr. Valentine Blanchard, a good practical photographer, well known for his instantaneous views of the streets of London, has been very actively advocating the coating of the present pictures with a film of collodion laid on by a brush, and he has produced evidence that prints so treated are more stable than others. But the film of pyroxyline thus left upon the paper is itself of an unstable character, and there are other little practical objections to its use, which, however, would be readily encountered if confidence in the utility of the plan were once established. Other experimentalists have recommended the coating of the print with a good lac varnish, and pictures so treated have resisted the action of some destructive gases, which would have injured an uncoated print. Yet the safe exposure of a picture to one particular gas gives but approximate evidence as to the effects which would be produced by the long action of light and air. Another plan is that proposed by Mr. Cooper, who recommends the coating of the picture with paraffine and gum resin, which are applied dissolved in benzole. By his plan one part of dammar, mastic, or copal, and four parts of pure paraffine, are dissolved in benzole, and a little of the solution is rubbed over the picture with a tuft of cotton-wool; this causes slight cloudiness, which disappears when the face of the print is polished with a clean piece of cloth. The silver surface is thus covered with the very durable substance paraffine, and, from a chemical point of view, this is perhaps the best of the methods yet suggested to lengthen the lives of photographs. A photograph, when finished off by either of these plans, is a very complicated production, consisting of the unstable substance albumen, with a thin film of darkened silver which forms the picture upon its surface, the whole being then coated with a fine film of pyroxyline, resin, or paraffine. Sulphur is the deadliest enemy of the silver print, and as albumen contains sulphur, no chemist would like to guarantee the permanence of such pictures, with whatever film they might be coated.

In this dilemma, Mr. J. R. Johnson has just published an improved method of printing, which he says gives better pictures than at present, and of a far more durable character. Everybody who has seen them must have noticed the delicacy of the photographs turned out by Disderi, for they are black and white, like an engraving, and have a very pleasing appearance. They are evidently not printed in the ordinary manner; in fact, they are copied upon collodion, and the film is afterwards transferred from glass to the paper, and then mounted in the ordinary way. Mr. Johnson states that his process produces pictures like those of Disderi. The negative is taken in the ordinary way, but is not intensified so much as usual, and positives or collodion are taken from it, by means of a copying camera. He prepares the plates for the positives by coating them with a thin film of white wax dissolved in sulphuric ether. When the film is dry it is polished with a little dry cotton-wool. It is then coated with a bromo-iodized collodion, slightly tinged by the presence of free iodine, and sensitized in a bath containing a trace of free nitric acid. The plate should then be slightly over-exposed, and under-developed, to get clean shadows full of detail. A developer containing 10 grains of iron and 20 or 30 minims of acetic acid is employed to bring out the picture, which must then be thoroughly washed. He next immerses the picture in a bath, containing 20 grains of bichloride of mercury, 20 grains of chloride of ammonium, and a few drops of hydrochloric acid, to each ounce of water, and the plate is left therein till the picture disappears, or becomes quite white. After this operation, it has again to be thoroughly washed, then it is fixed in hyposulphate of soda, which restores its black colour, after which it is again washed.

The picture thus completed upon glass has to be transferred to paper. Mr. Johnson uses ordinary albumenized or gummed paper, previously coated with a solution of 10grns. of gelatine, 1oz. water, and enough Chinese white from a water-colour tube to render the solution opaque. The paper may be allowed to dry. When the transfer is to be made the paper should be wetted, and laid upon the collodion picture, taking care to place it on in such a way that air-bubbles shall be excluded. A piece of blotting paper should then be laid over it, and pressed, and the plate stood on end to dry in a warm room. The film may then be removed from the glass, for the collodion picture will attach itself to the paper, and a good black and white enamel-looking picture is the result. Mr. Johnson considers that the pictures thus taken contain more sulphide of mercury than metallic silver, and are consequently more permanent than ordinary photographs.

Within the next few months, all these plans of printing on paper will undergo rigid scrutiny by practical men, though none of them

Digitized by Google

at present are admitted to be satisfactory. Those who now want small permanent photographs cannot do better than adhere to small transparencies on glass, with a second sheet of glass cemented over the face of the picture with Canada balsam, in the same way that glasses of achromatic lenses are cemented in optical contact with each other.

STREET TRAMWAYS.

THE promoters of a scheme of tramways, for certain streets and thoroughfares of London, who have unsuccessfully petitioned Parliament in the last two sessions for powers to carry their project into effect, have, for the third time, published the prescribed notices of their intention to apply for a bill in the session of 1868. The plans and sections, descriptive of their scheme, have, in accordance with the standing orders of Parliament, been duly lodged in certain public offices in the localities proposed to be affected, and in the private bill offices of Parliament. It is now many years since tramways were laid in Westminster, Birkenhead, and elsewhere in this country, but those first laid—on Train's plan—were open to the insuperable objection that they broke the level of the street, and were dangerous to ordinary street vehicles. In attempting to cross the lines they were subjected to rude shocks, and were dragged along the lines in a strained course to the damage of the vehicles, and the peril of drivers, passengers, and horses, and to the injury of the tramway itself, by wrenching the fastenings and throwing the rails out of gauge. The system now proposed by Messrs. John Noble and Co. obviates these objections, inasmuch as the tramways they propose to lay down will not break the level of the street, or prevent the passage upon the roadway, in any direction, of ordinary carts and carriages. The crescent rail, which they propose to employ, has already been fully described in the MECHANICS' MAGAZINE, and it is unnecessary to do more now than recall the statement that the rail will be on a level with the street both on its outer sides and between the rails. The only break on the surface will be a groove at the inner side of the rail for the flanges on the wheels of the tramway cars; such groove being too narrow to take in the tire of any ordinary street vehicle. A tramway upon this system does not present any objection of a mechanical nature, unless perhaps it be the liability of the groove to get choked up with ground stones and street waste, but a preventive of this result may be easily provided. If the continued public use of the whole width of the road can be preserved, it seems difficult to conceive any objection that can be urged against a trial, at least, of the system in some of the thoroughfares of London.

Wherever street tramways have been laid, the shopkeepers and owners of property have found that their trade has been greatly increased, and the value of their property enhanced, by the adoption of the improved mode of conveyance. This has been notably the case at Birkenhead and Liverpool. In the former town, some of the shopkeepers of Argyle-street objected to the tramway in that street, and it was in consequence diverted. They soon found that they had gained a loss, and petitioned, but too late, to have the tramway restored. In Liverpool some of the traders of Bold-street had opposed the project to lay a tramway in that fine thoroughfare, but they are wise in time, and are now very much in earnest that Bold-street should be embraced in a scheme now proposed for Liverpool. Two of the lines proposed to be laid by the Metropolitan Tramway Company pass through St. Pancras and Marylebone, and considerable activity is being manifested in these districts in relation to the scheme. An opposition is threatened, but by whom instigated or led does not seem quite clear. The promoters should be pleased rather than otherwise by an opportunity of exhibiting the voluminous and conclusive evidence which, we are informed, they have collected in support of their application; to the effect that the tramway carriages are much more comfortable and commodious than the ordinary street omnibuses, that they run much more quickly and smoothly, and with less noise, that they convey a larger number of passengers in a smaller number of vehicles, and can afford to do so at lower fares than the ordinary conveyances. Train's tramway—whatever its shortcomings in other respects—bore ample testimony on these points, to which we can speak from experience. As regards the maintenance of the road, the company takes the entire cost of maintaining part of the width upon itself, and by its operations reduces the tear and wear upon the whole. Whatever the evidence pro. and con. that any trustworthy witnesses have to offer, it is desirable that it should be placed upon record, and that this important subject should be thoroughly ventilated, and a wise conclusion arrived at.

THE FRENCH MONITOR "ONONDOGA."

IN troubled times men often reason wildly, and believe that danger exists where it is not. The French have recently given us an example of this by the purchase, for a fabulous sum, of the Monitor "Onondoga," to prevent her falling into the hands of the Prussians. It must be borne in mind that neither the Minister of Marine nor the Navy are responsible for the purchase of this wretched specimen of a sea-going vessel; to the Minister of Foreign Affairs the honour solely belongs. Some time in the month of August last she sailed from New York for France, but was compelled to return to port, which, after a second refit, she left for Halifax, Nova Scotia, under convoy of H.I.M. frigate "Themis" and sloop "Phlegethon." Her behaviour at sea was deemed so unsatisfactory that it was decided on remaining at Halifax during the winter, and she is now safely moored alongside the Royal Dockyard.

As Englishmen have long been familiar with the external appearance of this sort of ship, I shall not enter into a long description of the "Onondoga," but only touch on a few prominent points of her construction, as one of a class which, according to the version of the citizens of the United States, is to cross the Atlantic, destroy the British Navy, put our towns under contributions, and return to America unscathed. These are pretty "tall words" to be addressed to a first-class naval power, and indicate either a great deal of boasting on their part or a lack of preparation on ours to meet such a novel method of warfare. I have for some time been of opinion that the stem is the best offensive weapon to encounter such vessels, and have before published the same. The "Onondoga" is 226 feet in length, 48 feet in breadth, and 13 feet in depth; draught of water when loaded, 11ft. 6in.; tonnage (inclusive of engine-room and bunkers), 1,000; horse-power, 140 nominally, but her purchasers affirm that she does not work up to 100; pressure on safety valves, 16lb.; consumption of coals about 16 tons per day; bunker room, 300 tons. She is armoured in a peculiar manner. First, there is 4½in. of plating, then 12in. of wood, which is covered with inch plates, and forms the external skin. The waterways are about 24in. wide; the deck is pine, but lined with iron underneath to keep out shell. Amidships is the smoke stack, and some 40ft. abaft and before it stand the turrets, which are worked by steam machinery below the deck. A wooden bridge connects the turrets, running on either side of the smoke stack, and is useful in stormy weather for a promenade. The upper deck is about 1ft. from the water, with a slight iron railing in lieu of a bulwark. This deck is painfully free from fittings, there being neither chocks nor pipes to anchor or moor by the stern. One pair of small bitts forward, a second pair abaft the companion on the quarter deck, and a few badly forged and worse fitted ring-bolts, comprise the whole, if we except the dead lights which are flush with it. The hawse holes lead through the bows into the lower deck, where the anchor is purchased by the aid of a small windlass. The accommodation for the officers and crew is cramped and uncomfortable; under steam in hot weather it would be impossible to live below, and no one but a salamander could cook in such a galley. With the engine fires out, and the thermometer on deck at 10deg. of Farenheit, the perspiration was streaming down the faces of the cooks.

The framing and general finish of the engines is rough in the extreme; even the save-alls and similar articles must have been fashioned by the rudest hands. Indeed, it is long since I have seen such inferior work in a Government ship. In the officers' mess-place, and also before the engine-room, are rotatory steam pumps. One happened to be disconnected as I passed, and I remarked that the faces of the valves were not only rough but the deep scratches left in casting had not been removed. These pumps can be driven either with steam from the main or an auxiliary boiler which stands in the engine-room. The main boilers are fitted with Martin's vertical tubes. I had no opportunity of examining how they were stayed, but the workmanship about the furnaces looked very inferior. The furnaces were athwartships, and in hot weather the stoke-hole must be almost unbearable.

Her armament, if it is ever placed on board, will be four of Rodman's 450-pounders. I am not going to discuss the merits of these guns for general service in comparison with our own. I would simply remark that for the various services which a ship may be called on to perform I should prefer the English 12½-ton rifled gun. I do not believe, however, that England, or any other nation, need trouble themselves on this subject, for a ship which cannot move without convoy, or steer within any reasonable number of points, is not likely to inflict much damage on her enemies in a naval engagement. Truly, the Prussians must be a dangerous people, when the possibility of such a ship falling into their hands causes uneasiness to a nation of warriors, and sends them across the Atlantic to purchase, at any price, such a bugbear. As a point of honour, they will try next year to navigate her to France; after that is accomplished, I am of opinion that her services will be adapted for harbour only. X.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

EFFECT OF SUNLIGHT ON GLASS—PAINT—DRYING OILS, AND THE BEST PROTECTING COAT FOR IRON—NEW VOLTAIC PILES—TEST TO DISTINGUISH BETWEEN CARBOLIC ACID AND CREOSOTE—A HARMLESS FORM OF PHARAOH'S SERPENTS—THE INDUSTRY OF BARIUM.

SOME months ago, we noticed the experiments and observations of Mr. Gatfield and M. Pelouze on the changes of colour in glass effected by exposure to sunlight. In the last number of the "American Journal of Science," the first-named gentleman concludes his observations, from which we gather some interesting practical information. It will be readily seen that the choice of glass for a photographer's room is a matter of great importance to him. Photographers have remarked that they could take better pictures in a newly-glazed room than in one long exposed to sunlight. The explanation of this is clear. A glass containing iron becomes yellowish on exposure, and thus the transmission of the actinic rays is seriously interfered with. The best glass for photographers, Mr. Gatfield says, is a pure glass of light green or bluish-white colour. These

Digitized by Google

are the most free from the oxides of iron and manganese, the latter of which the author believes to be the cause of nearly all the changes he has noticed. There are many, we dare say, who will be inclined to doubt the reality of the changes of colour described. To convince such, Mr. Gaffield suggests a simple experiment. Let them take a piece of glass, and cover a part with a strip of black paint. Let it then be exposed for some months, and after this time let the paint be cleaned off. The difference in colour between the exposed and protected part will be at once evident to every observer. The author also points out that when an old pane of glass is removed from a window the colour of the glass under the putty is very different from that exposed to light. To glass makers the practical result of the author's experiments is to suggest great care in the selection of their materials. Iron and manganese are to be specially avoided in the manufacture of the better kinds of plate and sheet glass. The author speaks well of English crown, but states that the most permanently enduring kind of plate glass he has met is a superior kind of white plate made by the French and Belgian plate glass companies, and a German crystal plate made in Hanover.

The celebrated chemist Mulder has recently published a very valuable work on paint. The starting point of his investigations was an enquiry as to the best material to protect iron from rust. The result has been his rejection of all oil paints as unlikely to answer the purpose, and his conclusion that coal tar contains the best materials for a protecting coat. The author very completely investigated the nature of paint, and the chemical changes involved in the drying of oils. As regards linseed oil, we are told that the essential constituent is "linolein," a compound of glycerine and linoleic acid. The latter body the author could not obtain quite pure, but he decides that its formula is HO, $C_{32}H_{27}O_3$. When exposed to air linoleic acid rapidly oxidizes, first to "linoxic acid," a sticky body resembling turpentine. On longer exposure, "linoxyn" is produced. This is a tough leathery substance, sharing, we may say, many of the properties of caoutchouc. It is soluble in the same menstrua, and can be vulcanized like india-rubber. It is manufactured in considerable quantities in this country, and is the binding material used to consolidate emery wheels. It forms also the surface of linoleum cloth. According to Mulder, there are two linoxyns, the white and red; the white modifications become red on exposure to 80deg. Centigrade, and the red again turns white on exposure to sunlight. The browning of white paint in dark places, the author ascribes to the gradual change of white linoxyn into red. Oxidation does not end with the production of linoxyn. It still proceeds to the complete decay of the material, as is seen in very old paint.

One useful result of Mulder's labour is a simple process for preparing a good colourless drying oil. For this purpose it is only necessary to boil linseed oil for two hours with 3 per cent. of red lead, filter it, and then expose it to sunlight in large shallow vessels, frequently renewing the air above. Another result is a denial of the existence of albuminous and gummy matter in linseed oil, to which are ascribed the slowness of drying of unboiled oils. For these matters, Mulder searched in vain, and, at last, came to the conclusion that they had no existence. Oxides and acetates of lead, he tells us, act as driers not by precipitating albuminous matters, but by forming a little linoleate of lead, which rapidly oxidizes and communicates its activity to the oil. We shall return to this subject with fuller information on the chemistry of paint when we have Mulder's book before us.

Bottger has recently described some cheap and simple modes of constructing galvanic batteries when constant currents of long duration are required, as for electric clocks and bells. He takes a glass or earthenware jar and places in it a hollow cylinder of zinc, within which, placed so as the two do not touch, is set a cylinder of retort coke. The space between the coke and the zinc is filled up with a mixture of equal parts of common salt and sulphate of magnesia, heaped up a little, and wetted with a strong solution of the two salts. As many of these cells as may be necessary may be connected in the usual way.

Not quite so easy of construction is another battery described, in which no porous cell is required, and no evolution of gas in the action. A hollow cylinder of gas coke is first made, 8in. high, ½in. thick, and 3in. in diameter. This is varnished on the outside, and within it is set a solid cylinder of amalgamated zinc, which is kept in its place by means of cork. The vessel is then filled with a mixture of equal weights of water and persulphate of iron. The action of this battery goes on until all the ferric is converted into ferrous salt.

Two modes of distinguishing between carbolic acid and the true creosote from beech wood tar are given by H. Rust. Collodion and carbolic acid when mixed form a gelatinous mass, of which some use is made in surgery. True creosote and collodion, on the contrary, form together a clear solution. Another test is a solution of perchloride of iron to which sufficient ammonia has been added to form a little permanent precipitate. Carbolic acid added to this mixture gives a blue or violet colouration; creosote gives a green colour which turns to brown.

Pharaoh's serpents had but a short day, one reason for which no doubt was the poisonous nature of the sulphocyanide of mercury, of which they were made. If any one should care to introduce a harmless variety of the toy, Vorbringer tells him how to make it. He takes the black acid residual liquor of the purification of coal oils with sulphuric acid, and treats it with fuming nitric acid. A dark-coloured resinous matter swims on the surface of the mixture, which the author collects, presses, and dries, when it forms a yellowish-brown mass having about the consistence of sulphur which has been melted and poured into water. The mass, we may say, is evidently an impure picric acid. However, it is easily ignited, and on combustion undergoes a vast increase of bulk. The author states that a cylinder one inch long will give a snake about four feet long.

The great importance of the industry of baryta induces us to quote another mode of treating the impure native sulphate, first, to extract the sulphur, and next to make a pure sulphate, or permanent white, as it is called, which is well known to possess many advantages over the ground native sulphate, if ever so white. This industry has been carried on with partial success by Kuhlmann, of Lille, but the process is defective, and Dr. Wagner has improved it as follows:—The sulphate is first reduced to sulphide by calcining four parts ground to a fine powder with one part of coal in powder and from 5 to 8 per cent. of coal tar. This calcination is effected in iron crucibles, and continued for several hours. The mixture is then removed from the crucibles and recalcined on the floor of a closed furnace, so as to prevent any oxidation. When cold the sulphide so formed is treated with hydrochloric acid, leaving, however, the liquid alkaline to keep metals out of the solution. The solution of chloride of barium so obtained is precipitated with sulphuric acid to form permanent white, or is sold to remove incrustations from steam boilers, for which it is largely employed. When hydrochloric acid is added to the sulphide of barium, sulphuretted hydrogen is of course evolved, the sulphur of which is separated by bringing the gas into contact with sulphurous acid gas. When these two gases react, water is formed, and sulphur is separated according to the following equation:—

$$2\,H\,S \quad S\,O_2 = 3\,S + 2\,H\,O$$

The profit of this operation would depend upon the cost at which the sulphurous acid is obtained; and Dr. Wagner suggests that it might be made a means of utilizing the gas evolved when metallic sulphides are roasted in free air. It might perhaps be possible to make the process available at Swansea or St. Helen's.

THE THAMES EMBANKMENT WORKS.

MR. BAZALGETTE, the Chief Engineer of the Metropolitan Board of Works, has reported the following progress of the Thames Embankment Works:—As regards that portion between Westminster and Waterloo bridges, the whole of the dams had been completed, and considerable portions thereof had subsequently been removed from the face of the work. A length of 3,700ft. of the low level sewer, 3,400ft. of the subway, 3,019ft. of the smaller sewer for intercepting the several drains discharging in the foreshore, and 284ft. of the flushing culvert, is complete. The Westminster steamboat pier and the Charing-cross steamboat pier were in progress, and other necessary works were considerably advanced. Filling in behind the embankment walls and in the works generally had been carried out to the extent of about 500,000 cubic yards. For the purposes of the Waterloo and Whitehall Railway, the outlet portions of the Victoria-street and Regent-street sewers, from Scotland-yard to the Thames, had been diverted, and the sewers constructed in the new channel, and part of the railway tube has also been formed. With respect to the contract between Waterloo-bridge and the Temple-gardens, a length of 1,290ft. of the parapet was complete, and there remained but 210ft. to be formed to complete the entire length of the river-wall comprised in the contract. The Temple steamboat pier was also in a forward state, not more than 2,000 cubic feet of stone, the whole of which was upon the ground, being required to complete this portion of the work. The approximate cost of the whole of the works executed, including £350 for the materials upon the ground, was £224,600, of which the sum of £1,069 was due to the progress made in the past month. The whole of the roofing of the engine-house of the Abbey-mills Pumping-station was complete, with the exception of the portion to be occupied by the cupola, which was also in a forward state. The bedding of the stonework on the top of the brick shafts was in active progress, and the paving of the boiler-house was entirely completed. The reservoir for the water supply to the banks was fast progressing; the culvert and pipes from the Abbey-mills River were laid, and the foundations for the external walls were being got in. The total estimated cost of the completed works was £161,080. As regards the south side of the river, of the 2,370 feet of dam and staging constructed between Westminster and Lambeth bridges, 1,100 feet had been removed from the face of the works. Within the completed dams a length of 1,900 feet of the river wall had been constructed to a height of 7¼ feet above Trinity high-water mark, and other parts of the work had been greatly advanced. The approximate value of the whole of the completed works, including £23,800 for the materials upon the ground, is £147,000, of which the sum of £1,000 was due to the progress made in the past month.

LOSS OF THE UNITED STATES STEAMSHIP "MONONGAHELA."

THE following is a copy of Commodore Bissell's report to his government upon the loss of the American steamship "Monongahela." It is dated November 21, 1867:—I have to state, with deep regret, that the United States steamship "Monongahela," under my command, is now lying on the beach in view of the town of Fredericksted, St. Croix, where she was thrown by the most fatal earthquake ever known here. The shock occurred at three o'clock p.m. of the 18th inst. Up to that moment the weather was serene, and no indication of a change showed by the barometer, which stood at 30deg. 15min. The first indication we had of the earthquake was a violent trembling of the ship, resembling the blowing off of steam. This lasted some thirty seconds, and immediately afterward the water was observed to be receding rapidly from the south. In a moment the current was changed and bore the ship toward

Digitized by Google

the beach, carrying out the entire cable and drawing the bolts from the kelson, without the slightest effect in checking her terrific speed toward the beach. Another anchor was ordered to be let go, but in a few seconds she was in too shoal water for this to avail. When within a few yards of the beach the reflux of the water checked her speed for a moment, and a light breeze from the land gave me a momentary hope that the jib and foretopmast staysail might pay her head off shore, so that in the reflux of the wave she might reach waters sufficiently deep to float her, and then be brought up by the other anchor. These sails were immediately set, and she paid off so as to bring her broadside to the beach. When the sea returned, in the form of a wall of water twenty-five or thirty feet high, it carried us over the warehouses into the first street of the town. This wave in receding took her back towards the beach, and left her nearly perpendicular on the edge of a coral reef, where she has now keeled over to an angle of 15deg.

All this was the work of a few moments only, and soon after the waters of the bay subsided into their naturally tranquil state, leaving us high and dry upon the beach. During her progress toward the beach she struck heavily two or three times; the first lurch carried the rifle gun on the forecastle overboard. Had the ship been carried ten or fifteen feet further out, she must inevitably have been forced over on her beam ends, resulting, I fear, in her total destruction, and in the loss of many lives. Providentially, only four men were lost; these were in the boats at the time the shock commenced. The boats that were down were all swamped except my gig, which was crushed under the keel, killing my coxswain, a most valuable man. During this terrific scene the officers and men behaved with coolness and subordination. It affords me great pleasure to state that after careful examination of the position and condition of the ship I am enabled to report that she has sustained no irreparable damage to her hull. The sternpost is bent, and some twenty feet of her keel partially gone; propeller and shaft uninjured. The lower spintle of the rudder is gone, but no other damage is sustained by it. No damage is done to her hull more serious than the loss of several sheets of copper, torn from her starboard bilge and from her keel She now lies on the edge of a coral reef, which forms a solid foundation, on which ways may be laid. She can thus be launched in ten feet of water at one hundred feet from the beach. Gentlemen looking at the ship from shore declare that the bottom of the bay was visible where there was before, and is now, forty fathoms of water.

To extricate the ship from her present position, I respectfully suggest that Mr. J. Hanscom be sent down with suitable material for ways, ready for laying down, and india-rubber camels to buoy her up. I think there is no insuperable obstacle to her being put afloat, provided a gang of ten or twelve good ship carpenters be sent down with the naval constructor, as her boilers and engines appear to have sustained no injury. A valuable ship may thus be saved to the navy, with all her stores and equipments.

THE MECHANICAL VENTILATION OF MINES.

THIS important subject has been discussed several times by the members of the South Wales Institute of Engineers. At the annual general meeting of the Institute recently held it again formed the subject of some interesting remarks. Mr. Bates, after stating his ideas upon the subject generally, observed:—Mr. Pearce, in his paper on Mechanical Ventilation, has given some valuable information, also the results of some useful experiments at Pelton and Elswick Collieries, with Guibal's fan, as well as some very useful statistics gathered from various sources. At Pelton, in the fifth experiment, with 64 revolutions, the shutter half open, and horse-power of engine 58·18, they got 106,802 cubic feet of air per minute, with a water gauge pressure of 2·8 inches, which gives 80·99 per cent. of power utilized, excluding back pressure, an extraordinary percentage indeed; and in the ninth experiment, at Elswick, they have, with $57\frac{1}{4}$ revolutions, the shutter half open, and 19·73 horse-power or engine, 60,441 cubic feet of air per minute, with a water-gauge of 1·4in. which gives 67·56 useful percentage of the power transmitted to the fan, which is also very good. We have also commenced a fan on Guibal's principle at the Gethin Collieries, belonging to the Cyfarthfa Ironworks. The diameter of the fan is 29ft. 6in.; breadth, 9ft. 8in.; diameter of engine cylinder, 2ft.; length of stroke, 2ft. 6in. over vanes. The results are as follows:—

No. of experiments.	Position of shutter open.	Revolutions per minute.	Pressure on piston, not including exhaust.	Pressure on piston, including exhaust.	Horse-power, not including exhaust.	Horse-power, including exhaust.	Cubic feet of air per minute near the fan.	Water-gauge at the fan.	Cubic feet of air per minute in the mine.	Water-gauge in the mine.	Horse-power in air.	Percentage utilized, exhaust not included.	Percentage utilized, exhaust included.

We have also obtained the workings or the general results of a Struvé ventilator working at Risca Colliery, with two tanks 18ft. in diameter each, 6ft. stroke, and eight strokes per minute, driven by a single engine, 18in. in diameter of cylinder, 3ft. stroke, and 35lb. steam pressure; this gives the horse-power of engine 41·51, allowing one-fifth for friction. Under these conditions 43,866 cubic feet of air per minute was got, with a water-gauge pressure of 2·31in. This gives the power utilized, or duty done, to be 38·37 per cent. The capacity of these tanks at the above dimensions and rate of going is nearly 49,000; and at this place a furnace was put into operation to supplant the ventilator; and the average of twenty-four experiments or working days, commencing July 19, 1863, and ending August 28, of the same year, show that mechanical power, as a means of ventilating coal mines, is above that of the furnace, except under the circumstances of extraordinary deep pits, with an average barometer when the furnace was at work of 30·8in., and a water-gauge pressure of 1·41in., they got 34,088 cubic feet of air per minute. The furnace was stopped and the ventilator set to work again, with an average barometer of 30·4in., which is near to the case of the furnace, and a water-gauge pressure of 2·31in., we got 40,866 cubic feet of air per minute, showing in favour of the ventilator 9·778, and nearly 1in. of water pressure. We will now analyze these results of the ventilator and the furnace, then we will be able to see the relative merits under these conditions. Experiments of this description are very useful, and, as I have said before, the particulars and details ought to be carefully registered. But in this case it is to be regretted that the temperature of the downcast and upcast pits are not given, which makes the calculations a little more tedious to arrive at the two systems. Notwithstanding this, as the time of year is given, and the knowledge we have of temperatures in furnace pits, we may suppose very near what it would be; therefore, we will assume the average temperatures of the two pits to be 50deg. and 170deg. respectively; and by using one of the usual formulas to find the weight of a cubic foot of air under any temperature or pressure, we may test our suppositions in order to see if they will confirm this state of things. We shall thus find ·08019lb. the weight of a cubic foot of air in the downcast pit, and ·06489lb. the weight of a cubic foot of air in the upcast pit. Then ·08019 — ·06489 = ·0153lb. the difference per cubic foot between the two pits, this into the depth of the pit. Whence .0153 — 480 = 7·344lb. pressure per square foot area, this divided by 5·2lb., the pressure per square foot area for 1in. of water-gauge. We have 7·344 — 5·2 = 1·412, the water-gauge got by the furnace; therefore, this proves our hypothesis to be near the truth. I will now apply an ordinary process of reasoning to arrive at what depth the pit ought to have been to equal the power of the ventilator at these temperatures, and find it to be 785·27ft. the depth of the pit, and consequently 2·31in. water-gauge, the same as that which the ventilator produced when at work. Again, if they took the temperatures instead of the depth, we will see what temperatures it would have taken in the upcast pit of 480ft. in depth to equal the power of the ventilator. Whence, as 278deg. nearly is the temperature required to raise the water-gauge 2·31in. under the same conditions, and by using the formula as before, we have ·055lb. the weight of a cubic foot in the upcast pit, and ·0801lb. the weight of a cubic foot at 50deg.; therefore, 2·32in. is the water-gauge that these temperatures would give under the same circumstances, which equals nearly the water indication got by the ventilator; or, if we take the given quantity of air, together with the water-gauge in these cases, in order to see if the quantities correspond, we ultimately get 34,271 cubic feet, which is very near to the quantity measured when the furnace was at work—34,088 cubic feet; therefore, it is plain it would have taken a pit 785ft. deep, instead of 480ft., or an average temperature of 278 deg., which is almost impossible to be got, to equal the power produced by the ventilator.

Mr. Wilkinson gave the following results of experiments upon Guibal's fan ventilation at work at the Middle Duffryn Colliery, taken with a view of ascertaining the best position of shutter, the engine being driven at a uniform rate of fifty revolutions per minute:—

No. of experiment.	No. of strokes by engine.	Pressure of steam.	Extent of shutter open.	Area of shutter open.	Number of revolutions of anemometer.	Area of space under fan where experiments were taken.	Total quantity of air going through workings.	Area of space between the fan and upcast shaft, where the experiments were taken.	Revolutions of anemometer.	Total quantity of air ascending the upcast shaft.	Water-gauge at 30 yards from pit bottom.	Water-gauge on surface.
1	50	34	7 in.	5·83	4·00	83·19	33,276	80·61	4·50	36,274	·25	·30
2	50	34	1 ft.	10·00	4·50	83·19	37,435	80·61	5·13	41,352	·50	·55
3	50	34	2 ft.	20·00	5·00	83·19	41,595	80·61	5·75	46,350	·62	·70
4	50	34	3 ft.	30·00	5·50	83·19	45,754	80·61	6·62	53,363	·68	·80
5	50	34	4 ft.	40·00	5·00	83·19	41,595	80·61	7·00	56,427	·62	·80

Barometer on surface, 28·60; thermometer on surface, 53. Barometer underground, 29.15; thermometer underground, 54. Air going through fan at second experiment:—8 revolutions of anemometer × 70 area of space = 56,000. Third experiment:—8·25 revolutions × 70 area of space = 57,750.

Mr. Thomas attributed the loss of Mr. Wilkinson to a leakage in his valves, and contended that he ought to have got 65,000 cubic feet of air through his upcast instead of only 40,000. At his pit they were able to get from 56,000 to 67,000 cubic feet at a very reasonable velocity.

Mr. Wilkinson said the difference spoken of by Mr. Thomas was easily accounted for, through the fact that his upcast was from 50 to 60 yards higher than his downcast shaft, whereas his (Mr. Wilkinson's) upcast and downcast shafts were upon the same level.

Mr. George Elliot said that he had been working Struvé's fan at one of his collieries for ten years. It had been of great service, because although in its effects not equal to the furnace, it was a substitute for the furnace when the application of the latter would have been attended with difficulty and danger. With regard to the fan ventilators, of which they had heard so much, two or three were in existence in that part of the country; and others were in operation in the county of Durham. It was his opinion that the day was not far distant when furnace ventilation would be entirely superseded by the use of mechanical ventilation. He believed, moreover, by such appliances they would very much add to the safety of mining operations. The question of higher water-gauge was merely a question of force of friction, whether the machine was Struvé's or Guibal's; and, therefore, if they made the engine large enough, and the air course small enough, they would get plenty of water-gauge.

MAGNETO-ELECTRIC SIGNALLING APPARATUS.

BY M. AUGUSTE BERLIOZ.

FIG. 1.

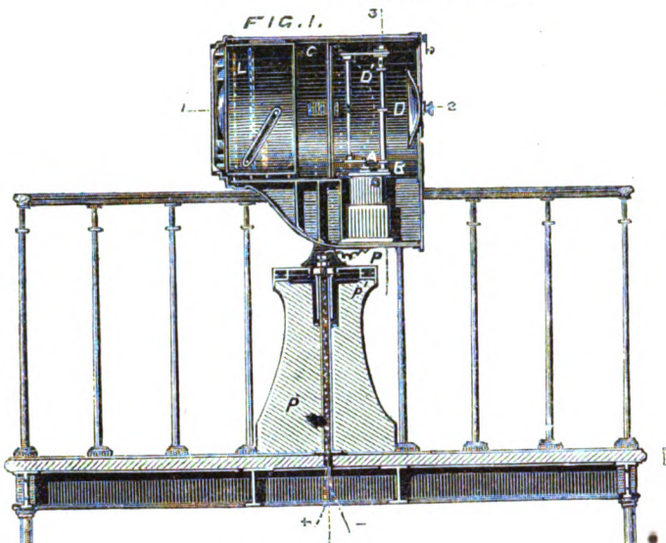

FIG. 3.

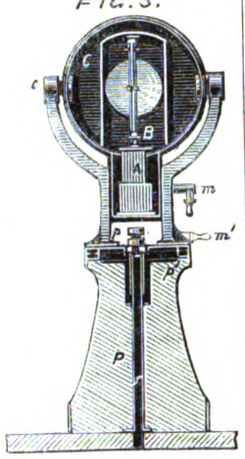

FIG. 2.

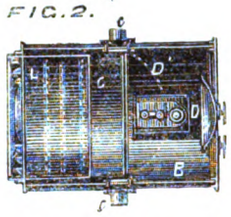

FIG. 4.

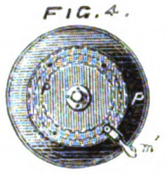


They need not, therefore, waste time in discussing that point. But it seemed anomalous that with the same power (Struvé's ventilators in both cases), Mr. Thomas should be able to get 10,000ft. more than Mr. Wilkinson, he having 2½in., and Mr. Wilkinson ½in. water-gauge. There must be some inaccuracy in the statements. It would, from what was being done in that district and other parts of the country, become apparent that to get any necessary quantity of air underground all that would be requisite would be to have sufficient power with the fan, or whatever other appliance might be employed, and to have the air courses sufficiently large.

BERLIOZ'S MAGNETO-ELECTRIC SIGNAL LIGHTS.

AT the present time, when "the rule of the road at sea" is one of the topics of discussion, it will not be inappropriate to introduce to the notice of our readers an invention bearing very closely upon the question. This is a system of magneto-electric signal lights, the invention of M. Auguste Berlioz, an electric machine maker, of Paris. This invention has reference particularly to the application of a peculiar arrangement of magneto-electric signal light apparatus to ships for the purpose of showing their course, and for the purpose of illuminating a portion of a coast, and for showing the works of an enemy by night. Fig. 1, in the accompanying engraving, is a longitudinal section of the apparatus mounted; fig. 2, a horizontal section taken on the line 1, 2; fig. 3, a vertical section taken on the line 3, 4; and fig. 4, a plan of the part which admits of the motion of the apparatus in a horizontal plane.

The apparatus is composed of a copper cylinder C mounted on trunnions c in supports fixed to a plate p which rests on a fixed metallic base plate p^1, forming the top of a pillar P somewhat similar to a capstan; this pillar is secured to a platform provided with hand rails, and is erected on the deck of the ship. The back part of the cylinder communicates with a chamber B in which the electric lighting apparatus A, consisting of a Duclos or other lamp, is placed. This lamp is connected by wires to one or two magneto-electric machines erected in the interior of the vessel, the wires passing through a hole x made in the centre of the pillar. The front part of the cylinder C is provided with a plano-convex stepped lens L, and, at the end of the part B, that is, behind the electric lamp, there is a spherical reflector D, the light, of course, occupying the focus. A parabolic reflector, shown by the dotted lines D, figs. 1 and 2, may also be used behind the light; either of these reflectors may be employed to project the light. The lens is used to indicate the route, and the reflector to observe objects at short distances of, say, within one and a-half miles. The parabolic reflector is employed alone without the lens. The cylinder C after being inclined is turned round on its trunnions c to adjust it to the required angle with the horizon, in which position it is fixed by the bolt m, fig. 3. The cylinder is also capable of motion in a horizontal plane by turning the plate p on the surface plate p^1 of the pillar P. These plates are connected together by screws, the heads of which are inclosed in the recess in the plate p^1, and when the apparatus is adjusted to the required angle the two plates are held fast together by the bolt m^1 (figs. 3 and 4). The pedestal admits of the lamp being moved on each side of the longitudinal axis of the ship to about 135 degs. from the bow; this lamp is inclined, in order to indicate the course of the bow of the vessel.

M. Berlioz exemplifies three cases in which ships may avoid a collision when fitted with this apparatus:—First, two vessels running the one into the other proceed both "starboard" to avoid running foul. Second, with two ships following parallel routes there can be no collision, for they both proceed to "starboard." Third, the course of two ships being oblique, the rays of light meet together; these vessels each proceed to the opposite side of the meeting point of the half angle of convergence of the two routes. The ship at larboard allows that which is at starboard to pass, and indicates that it is diminishing its speed by ringing the bell.

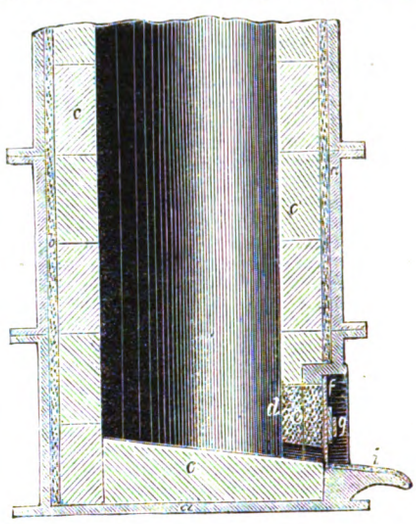
This apparatus may also be used to give night signals, whether in squadron navigation or for a ship aground. These night signals constitute a species of electric telegraphy; the apparatus with an ordinary lens, produces the numbers 1 to 3; the numbers 4 to 6 are found by employing a screen with a red glass before the lens; and the numbers 7 to 9, with a screen and a green glass before the lens. The interruption of the light indicates the number formed, for which purpose a black screen may be employed, or obscurations may be also made with a screen.

IMPROVED METHOD OF MANUFACTURING STEEL AND SOFT IRON.

MR. JAMES HARGREAVES and Mr. Thomas Robinson, the former an analytical chemist, and the latter an ironfounder, of Widnes, have conjointly patented an improved method of manufacturing steel and soft iron. Their invention consists in the use of any of the salts which yield oxygen on the application of heat, such as the nitrates, chlorates, chromates, manganates, and stannates, in combination with any of the oxides of iron or manganese, as agents to act on fused or molten cast iron to burn out therefrom at any desired speed the excess of carbon in, and at the same time to remove other impurities from the cast iron, and thereby convert it at one operation into steel or soft iron. The oxidizing salts are placed in contact with the fused or molten cast iron. The proportion of the salts to the oxide determines the rate at which oxygen will be eliminated, and the proportion of the converting agents mixed with the cast iron will determine whether the product is steel or soft iron; either can be produced. The object in employing these converting agents is to regulate the otherwise rapid action of the oxydizing salts. The oxydizing salt at present most suitable is nitrate of soda, in consequence of its lower cost and the high proportion of oxygen which it yields, as well as from the fact that the soda contained in it acts effectually in removing silicium, sulphur, and phosphorus.

The proportions of oxygen capable of being liberated or evolved from the oxydizing salts and oxides of iron and manganese are well known to chemists. The quantity of oxygen capable of being liberated from any given quantity of these substances mixed with clays, ochres, or other substances can therefore be ascertained with ease. The removal of carbon from molten cast iron by means of this invention is effected by converting the carbon into carbonic oxide or carbonic acid. When carbonic oxide is formed every eight parts of oxygen remove six parts of carbon, and when carbonic acid is formed every eight parts of oxygen remove three parts of carbon. Now, nitrate of soda in contact with molten cast iron will yield 47 per cent., sesquioxide of iron, 30 per cent., and binoxide of manganese about 36·25 per cent. by weight of oxygen. With the foregoing information the proportions of the materials required to form the converting agents, and the quantity of the said converting agents necessary to remove any desired amount of carbon to produce any desired quality of steel or iron can easily be ascertained. In all cases the soda contained in the nitrate is in excess of the quantity required to combine with or extract the silicium, sulphur, and phosphorus contained in cast iron if the cast iron is of ordinary quality.

When a separate converting vessel is used, it is formed as shown in the accompanying engraving,



which is a vertical section of the converter. a are semicircular pieces of metal bolted together; b, fire-clay backing, and c fire-brick lining; d is the discharging way closed by fire-clay e, door f, bar and wedges g in the same manner as a foundry cupola; h, the tap hole, and i the runner. The bottom slopes downwards towards the door, so that the whole of the charge run or poured in at the top may flow out. In practice, to make steel suitable for cutting tools for every hundredweight of white cast iron the following mixture is used:—Nine pounds of nitrate of soda and five pounds of binoxide of manganese are mixed intimately, and whilst in a moist condition are placed in the converting vessel, and tamped down tightly into the bottom. The nitrate of soda of commerce is generally sufficiently moist for the purpose without any addition of water. If the converting vessel has just been used, the heat will usually be sufficient to dry the mixture into a solid mass. If the heat is not sufficient a small fire-grate containing fire is placed over the converting agents. If the converting vessel has not been used immediately before filling in the converting agents it is heated by a fire, placed inside. The fused iron is then run into the converting vessel over the dried mass of the converting agents, when decomposition takes place, the oxygen and other products rising through the mass of molten metal and removing the excess of carbon as well as the silicium, sulphur, and phosphorus. The excess of carbon is removed by combining with oxygen and forming carbonic oxide, and carbonic acid, and the other impurities, together with the soda contained in the nitrate, when nitrate of soda is used, rise to the surface of the mass in the form of a slag.

When the converting agents have been decomposed, and no further gas is evolved, the vessel is tapped and the steel run out into moulds. At other times the inventors make steel suitable for cutting tools by using the same proportions of converting agents to those above mentioned, first making the converting agents into bricks or blocks and packing them tightly into the bottom of the converting vessel. When a separate converting vessel is used, it is

Digitized by Google

found in practice that the greater the depth of metal through which the products of the decomposition of the converting agents have to ascend the better are the results, inasmuch as the products have more time to burn out the carbon and absorb the impurities which it is desirable to remove from the iron. It is, therefore, preferable that the converting vessel should be narrow or small in proportion to its depth.

To make soft or malleable iron the inventors take for every hundredweight of white cast iron the following mixture:—Twelve pounds of nitrate of soda and eighteen pounds of sesquioxide of iron, mixing and tamping them into the bottom of the converting vessel, and in other respects proceeding as in making steel for cutting tools.

In the ordinary puddling furnace in the course of the ordinary process of producing malleable iron, the hematite ore is ground and mixed into a plastic condition, and to every three parts of the hematite is added one part of nitrate of soda, the mixture being made into balls or blocks. While the blocks are soft they are fixed on the ends of rough puddled billets, and then thoroughly dried. As soon as the cast iron is melted in the puddling furnace the balls or blocks are pressed down to the bottom of the metal, when the gases and other products evolved cause violent agitation and effect the removal of the excess of carbon and other impurities, thereby reducing the time required to bring the iron to nature, producing a better quality and a larger quantity as the converting agents supply iron. To the charge of an ordinary puddling furnace containing about 480lb. are added 32lb. of the mixture of hematite and nitrate of soda.

COLOUR OF THE CLOUDS AND SKY.

A SHORT time ago "Poggendorff's Annalen" contained a paper by M. Lommel on "The Evening Glow and Similar Phenomena"; but before the apearance of that paper, Mr. Sorby had discussed the same subject in a more popular form, extending it to the colours of the clouds and sky, which he explains on the principle that the clear transparent vapour of water absorbs more of the red rays of light than of any others, whilst the lower strata of the atmosphere within no great distance from the surface of the earth, offer more resistance to the passage of the blue rays. This is especially the case at sunrise and sunset, and very perceptible in the case of dark-coloured fogs, through which the sun appears red. This is often due to only a few hundred yards' thickness of such a fog, and it is highly probable that the same effect will be produced by a thickness of as many miles of pure air containing watery particles very thinly disseminated. It is thus Mr. Sorby explains nearly all the phenomena connected with the question. The blue colour of the sky is due to the absorption of a considerable amount of red light by aqueous vapour, far from the earth's surface; but if minute particles of liquid water form a thin mist, the blue of the sky will be diminished, as is the case in winter, and in cold countries. If the air be much charged with transparent vapour, the blue colour will be deeper, and will thus become an indicator of rain. At sunrise and sunset the light of the sun has to pass through about 200 miles of atmosphere within a mile of the surface of the earth, in order to illuminate a cloud a mile from the ground. In passing through this great thickness the blue rays are absorbed to a far greater extent than the red, and much of the yellow is also removed. Hence, clouds thus illuminated are red; but when the sun rises higher, the yellow light passes more readily, and the clouds become orange, then yellow, and finally white. Clouds in different parts of the sky, or at different elevations, might show these various colours at the same time, as indeed is often the case.

A YEAR'S SHIPBUILDING ON THE CLYDE.

THE year 1867, though by no means characterized by excessive briskness in the shipbuilding trade of the Clyde, and unable to stand a favourable comparison with the last five or six years, has yet produced a very large amount of tonnage in the various yards between Greenock and the Broomielaw—a greater amount, perhaps, than could have been expected. The number of vessels of all classes launched during the year, as we gather from exhaustive tables published in the "Glasgow Morning Journal," is 241, being only six less than 1866 and 26 less than in 1865, while, as compared with 1864, it is larger by 21. In respect of tonnage, however, the comparison is more unfavourable to 1867. During the past year the tonnage launched on the Clyde amounted to 114,598 tons, while in 1866, a year during which there was a long period of suspended operations, owing to the lock-out, the amount was 129,989; in 1865, 158,300; and in 1864, 134,000. The year 1864 may almost be regarded as an exceptional year, owing to the impetus given to the steam shipbuilding trade by the American war, many of the blockade-runners having been destroyed or used up, and their places supplied by the firms on the Clyde. A noticeable feature of the work of the past year is the large number of iron barges (exclusive of hopper barges) built on the river, no fewer than 56 of that class of craft having been launched, as compared with 32 in 1866, 25 in 1865, none at all in 1864, and 13 in 1863; 58 barges were launched in all, all being iron save two. Of paddle steamers there were 26 launched, as compared with 35 in 1866; of screw steamers (iron and composite), including hopper barges and dredges, 84, as compared with 121 in 1866; and of sailing vessels 75, as compared with 57 in 1866. With regard to the prospects for 1868, they are, so far as can be judged by the orders on hand, of a very favourable character. At present, the orders are for 130 vessels, including 5 gunboats, 5 screw armour-clads, 11 paddle steamers, 57 screws, 3 steam dredgers, 49 sailing vessels, and 2 iron barges, with a total tonnage of 115,124 tons. In 1866, at the same period, the orders on hand were 106 vessels, and 78,000 tons; and in 1865, 180 vessels, and 130,000 tons.

THE TRADE OF THE PAST YEAR.

TRADE matters, as a whole, possess but a limited interest for our readers. Some of its branches, however, are of importance to them, and we have, therefore, selected the following extracts from a series of reports which lately appeared in the "Times." They will be found to convey an idea of the leading features of each branch of our trade noticed during 1867. With few exceptions the markets have been characterized by a continuous fall in prices, and hence, although the extent of the business has been good, a feeling of uncertainty and dissatisfaction has been prevalent throughout. Grain importers and shipowners have been almost alone prosperous, the latter having been benefited not only by the wheat importations, but by the Abyssinian war.

AGRICULTURAL IMPLEMENTS.

We are happy to report a great increase in the demand for agricultural implements, particularly for reaping and mowing-machines. This is attributable mainly to the necessity for machinery which the increasing deficiency of agricultural labourers creates, especially in all that relates to the securing of crops, and also to the improvements recently made in constructing these machines. As the season advances the demand for such machinery will, doubtless, be largely increased.

METALS.

To review the metal trade for the past twelve months is by no means a pleasant task. All metals, with the exception of tin, have been signalized by a continuous fall in prices since the year commenced, and all through its progress there has been but one long cry of complaint on all sides. Hopes of a better tone in the markets have been raised from time to time by a slight demand springing up for a particular article, which led, however, only to disappointment and to a further reduction from even the low prices before ruling, till we have arrived at the commencement of another year with prices of most metals at lower rates than have ever been known before. To predict what the year now opening may produce to the metal trade is impossible, but with such low prices, trade depressed for the last two years, and money at a mere nominal rate, it is but reasonable to suppose that we have seen the worst, and that we may fairly calculate upon an increased demand and better prices.

PETROLEUM.

The features of the market throughout the year have been heavy stocks and declining prices. In the early autumn, on the rapid advance in America, refined Pennsylvanian S.W. petroleum rose to 1s. 7d. per gallon—indeed, in one case 1s. 7½d. was paid. This was the highest price of the year for spot. The lowest was in June, when 1s. was accepted for a parcel of 1,000 barrels, slightly inferior in quality. Cargoes ranged in value from 1s. 0½d. to 1s. 7½d. The fluctuations of the year have been both important and frequent, and as a consequence we have had considerable speculation. It was confidently asserted that the low quotations ruling everywhere for oil would tell materially on its production in the United States; at the same time it was foreseen that home-manufactured coal oil must cease to compete. The anticipated extinction of the coal oil trade has almost occurred, but the falling-off in supplies from the United States, so generally looked for, was not realized by the event. According to last advices, shipments from America were slightly in excess of those of 1866, although freights have ruled very high for some months past. The increase in the consumption here has been very great, but it is the general opinion that the deliveries would have been much larger but for the dulness of trade and distress among the poorer classes, the chief consumers of petroleum.

TIMBER.

In 1865 and 1866 we were overtrading in wood. The supply for seven years preceding 1860 had given an annual average of about 2½ millions of loads; for the three following years it became 3,000,000; in 1863 and 1864 the average rose to 3½ millions, and this expansion sufficing for our increasing consumption, the greater imports of 3 millions in 1865 and 1866 left a large unconsumed surplus. The importation of little more than 3,000,000 loads in 1867 takes us back five or six years for a parallel quantity; yet it has been enough for the demand of the building trade, and leaves ample stocks at the principal ports for consumption, while importation is suspended. The wood of the north of Europe has never before this time been laid down so cheaply at the principal ports of the kingdom, especially on the east coast; but we fail to see the wonted elasticity of our trade, which, after previous times of difficulty, had recovered from the troubles of one year before the end of the next. While merchants lack confidence, the public have profited by the depression of prices. To meet the increased difficulty of dealing with our skilled labour, foreign enterprise now provides the greater part of the timber sawn into deals, battens and boards very nearly in the form and shape required for use, instead of continuing to send so much timber in the log for conversion here by our own workmen. By the introduction of our machines large quantities of flooring boards have been prepared in Russia, Norway, and Sweden, so well made that they have become a regular importation in all parts of the country. So eager is this competition that an experimental trade has been commenced by the shipment of mouldings, and from Sweden of manufactured doors, well finished, and of the same patterns used by our builders. The colonial supplies, now contracted to one-third of our imports, have been chiefly and judiciously limited for several years to those descriptions of timber and other woods which are the peculiar growth of Canada and New Brunswick. The requirements of the northern provinces of the United States abstract a great portion of Canadian pine of the best sorts, and also draw from the upper lakes much wood which used to be carried to the Quebec market.

INDIGO.

Few articles of colonial produce have been so remunerative to the importer during the past year as indigo. The position of the dye at the commencement of 1867 was one full of promise; the general statistics of stocks, deliveries, and imports, combined with the low rate of money, with peace at home and abroad, seemed to justify the sanguine expectation of those whose commercial anticipations had been blighted in the previous year by a Continental war, monetary panic, and general commercial distrust. At the end of November, owing to telegrams from Calcutta announcing the high prices paid there at the opening of the auctions, a speculative inquiry set in, which raised the price here 3d. to 6d. per lb., or about on a par with the rates ruling in Calcutta, which are 25 to 35 rupees per maund above those of last year. The future prospects of the manufacture of indigo are exceedingly gloomy; the dislike shown by the natives to the enforced cultivation of the plants seem to increase; the growth of rice and other products used as articles of food are more profitable to them, and require less care and supervision. This, and the effects of the cyclone on the October plant, will render more than an average crop next season highly improbable. That indigo during the ensuring year will command relatively high rates, seem pretty certain; the low prices of cotton, flax, hemp, and jute, together with the abundance of money, all appear to point to this result; to these must be added the small stocks held by consumers and dealers both here and on the Continent.

HEMP.

The total shipments from St. Petersburg, which were reported in August would be 8,000 tons short, turn out to be only 3,738 tons below that of the previous year (1866). From Riga it is believed there are 3,000 to 4,000 tons short; but as the exact destination of the shipments from this port cannot be depended upon, it is impossible to say how much is the deficiency to the United Kingdom. The prospects of the coming season are, as usual, contradictory, and hardly any reliance can be placed upon reports; but, as the value for forward delivery is only £34 against £38 10s. on the spot, it is to be presumed that a large crop may be anticipated. Sisal hemp is a new fibre from Mexico, and has been used largely in substitution for Manilla hemp; in colour it rivals that fibre, but is deficient in strength. It has been introduced during the past year for the first time, and has sold at public sale as high as £54 per ton. About 1,200 tons have been imported, and it is said it can be produced in large quantities; should the high prices for hemps, which for so long have ruled, be maintained, it doubtless will form a staple article in the fibre market.

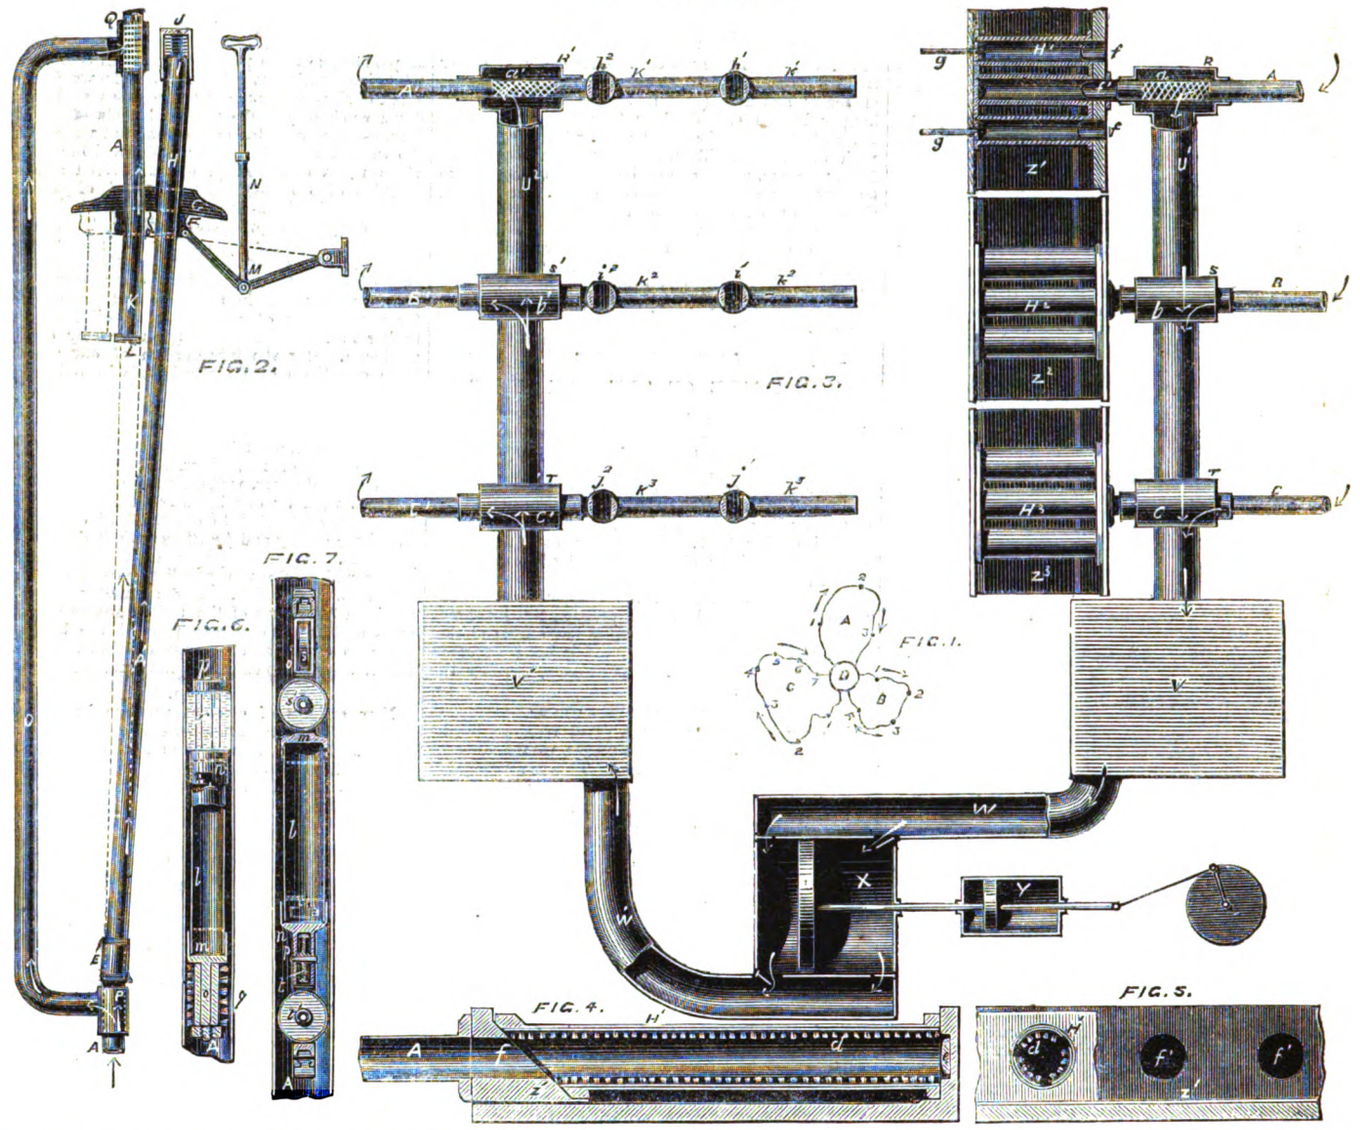
IMPROVED SYSTEM OF PNEUMATIC DESPATCH.

IN the ordinary arrangement for conveying letters or parcels through pneumatic tubes from one station to another, one end of the tube communicates with one station and the other end with the other station, the letters or parcels being conveyed through the tube inside piston carriages, which travel along the tube either by exhausting the air

Digitized by Google

IMPROVED SYSTEM OF PNEUMATIC DESPATCH.

BY MR. C. W. SIEMENS, C.E.



from, or by forcing it into the tube. The tubes are made of comparatively large diameter in order to provide sufficient room in the carriages for their contents, thus entailing both a great outlay in establishing the system of tubes, as also the erection of large pumping engines for producing the required pressure for propelling the carriages. In addition to this a loss of the propelling power is occasioned both by the leakage of the air past the carriages when they do not fit the tube completely, and from the fact that when a carriage arrives at the end station the air constituting the propelling medium of necessity escapes into the atmosphere.

It is now, however, proposed by Mr. C. W. Siemens, of Great George-street, Westminster, to obviate all these defects by an improved system of pneumatic tubes which he has recently patented. He proposes to use tubes of comparatively small diameter, and consequently of an inexpensive nature, so arranged that while the carriages or pistons travelling in the same are of correspondingly small dimensions, and consequently require no great power to propel them, the smallness of the capacity of the carriages is compensated for by the rapidity with which they may be dispatched in quick succession from one station to another, while practically no loss of propelling power from the before-mentioned causes can take place. For this purpose the system of pneumatic tubes is so arranged as to have no terminal points, but to form one or more closed pneumatic circuits, constructed of light wrought-iron tubes of small diameter fixed together by flanged joints, and communicating at one point (a central station) with an air pump. The air will thus travel round and round in the circuit continually in the same direction, so that on introducing a carriage containing the dispatches into the tube at the pumping station it would if not intercepted at an intermediate point travel right round the circuit and thus eventually arrive at the pumping station again. At intermediate points in the pneumatic circuit thus established are situated the stations to or from which dispatches are to be conveyed from or to the central or pumping station.

Fig. 1 of our engraving is a diagram of three closed circuits A B C, all communicating with the central pumping station D, the pump at which causes the air to travel continually round in each circuit in the direction of the arrows. Upon the circuit A are established three intermediate stations 1, 2, 3, on the circuit B are four stations, and on the circuit C are seven stations. The carriages containing the light objects to be forwarded are introduced into the circuits at the central station D, and are carried forward in the direction of the arrows by the circulating air. If the carriage introduced at D into circuit C is destined for the station 1, it is there intercepted in its course and removed from the circuit; if, on the other hand, it is intended for station 7, it is allowed to pass all the intermediate stations and is only intercepted at that point. If, on the other hand, a carriage is to be conveyed from the station 1 to the central station D, it is also caused on being introduced into the circuit at that point to travel all round the circuit in the direction of the arrows, passing all the intermediate stations 2 to 7 until it arrives at D.

Carriages containing the dispatches and other articles may conveniently be forwarded at certain fixed intervals of time from each of the intermediate stations upon one circuit to the central station, where they are sorted and dispatched to the local stations upon the same or other circuits for which they are intended; thus a dispatch letter dropped into the receiving box of station 2, circuit A, and intended for station 4 on circuit C, would proceed in the first place to the central station, where it would be placed with other letters or small parcels into the carriage intended for station 4 on circuit C. Upon its arrival at this station the contents of the carriage would be handed to carriers to be conveyed to their destination; also, if required, carriages may be forwarded from one intermediate station to another on the same circuit by being introduced into the circuit at the one station and intercepted at the other. For receiving dispatches or parcels from the circuit into the stations, a portion of the tube forming the circuit is arranged similarly to a switch on railways. At one point it is capable of being moved away from the circuit and made to communicate with a closed chamber, into which the carriage destined for the particular station is passed from the circuit. Its momentum is gradually absorbed in this chamber by a series of brushes or projecting pieces of india-rubber or leather, arranged longitudinally so as to produce a powerful drag upon the piston, the closed end of the chamber being provided with a buffer for the carriage to strike against.

At fig. 2 of the engraving is shown Mr. Siemens' arrangement for receiving and dispatching the carriages at the intermediate stations, together with the by-pass for keeping up the circulation of the air in the circuit. A A are portions of the tube forming the pneumatic circuit, and A^1 is the movable part or switch. This is connected to the tube A at one end by a flexible air-tight joint E, while the other end is carried in a slide F, fitting air-tight against the curved surface of the block G in which the other part of the tube A is fixed. In this block is also fixed the open end of the receiving chamber H, the other end of which is closed and is provided with buffer springs I, while a small hole J is formed in the end to allow of the escape of the air as the carriage passes in. The slide F carries the open end of the dispatching branch K, the other end of which is closed by a sliding cover at L. The slide is connected to the toggle joint lever M, which is actuated by the handle N so as to move the switch A^1 and dispatching branch K simultaneously either into the position shown in full lines or into that shown in dotted lines.

When in the latter position the switch tube A^1 is in a line with the circuit tube A, in which position it will allow any carriage or piston approaching the station in the direction of the arrows to pass it on its way to another station. When, on the other hand, the carriage is to be received into the station, the switch is moved into the position shown in full lines in front of the receiving chamber H, and the carriage passes from the former into the latter. At the same time the dispatching tube K is moved in front of the open end of the tube A, and any carriage that has previously been placed in it for conveyance to the central or other station consequently passes into

Digitized by Google

the tube A and is conveyed along the circuit, the current of air in which is maintained while the switch tube is thus diverted from it by means of the by-pass O. This is a tube communicating with the circuit at P and Q, so that the current of air passes uninterruptedly through from the part of the tube A just behind the switch to the other part beyond the switch, as indicated by the arrows. The communication between the by-pass O and the tube A is established by forming a portion of the tube A with perforations, enclosing which in an air-tight manner is the casing P and Q, thus forming an annular space round the tube with which the by-pass O communicates.

Fig. 3 shows the arrangement Mr. Siemens prefers to employ for dispatching the carriages from the central station to the intermediate stations of three different circuits in connection with it as indicated at fig. 1, and for receiving the carriages from the stations on those circuits into the central station. It also shows the mode in which the circulation of the air may be effected in the three circuits simultaneously by one and the same pumping engine. A A^1 B B^1 C C^1 are the three circuit tubes communicating on the one side with the dispatching chambers K^1 K^2 K^3, and on the other side with the receiving chambers H^1 H_2 H^3. Each of the tubes A B C is formed with perforations at points a a^1 b b^1 c c^1 just in front of the receiving and dispatching chambers. These perforated portions are enclosed in air-tight casings R R^1 S S^1 T T^1 communicating with the pipes U U^1. Each of these pipes opens into an air chamber V V^1 of sufficient capacity to equalize the flow of the air through the tubes, and which are put in communication by means of the pipes W W^1, with an air pump X, worked by a steam engine Y. The pump is surrounded by a casing, through which cold water circulates, to prevent the accumulation of heat by the compression of the air.

By the action of this pump the air is continually and simultaneously drawn from the parts A B C of the circuits through the perforations a b c, pipe U, air chamber V, and pipe W into the pump, as indicated by the arrows, and is forced through the pipe W^1, chamber V^1, pipe U^1, and perforations a^1 b^1 c^1 into the parts A^1 B^1 C^1 of the circuits, thus maintaining a continuous circulation of the air in each of the circuits. The ends A B C of the circuit tubes are fixed in an air-tight manner against the faces of three tables or troughs Z^1 Z^2 Z^3, in which are the movable receiving chambers H^1 H^2 H^3, of which there are three connected together to each circuit, in order to provide means for receiving the carriages arriving at short intervals without impeding the dispatch of business.

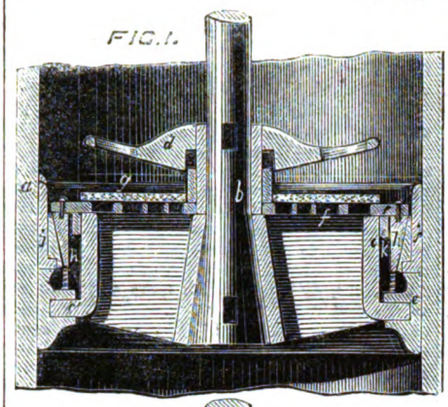
The construction of these tables and receiving chambers is shown to an enlarged scale at figs. 4 and 5. Fig. 4 shows a transverse section through one of the tables, and a longitudinal section through a receiving chamber, and fig. 5 shows a part longitudinal section through the table and a transverse section through one of the chambers. The chamber H^1 are made to fit air-tight, with smooth sloping surfaces at one end against the adjustable smooth sloping sides of the table Z_1 to which the tube A is fixed, while the other ends of the chambers may either be closed, as shown at fig. 3, or they may be open, as shown at fig. 4, and fit air-tight against the other side of the table Z^1, the weight of the chamber pressing against the sloping surface of the table tends to keep the surfaces in air-tight contact. An opening f is formed in the side of the table in continuation of the bore of the tube A, through which the carriages pass from this tube into the chambers H^1. These chambers are formed of thin sheet metal for the sake of lightness, and are provided internally with brush surfaces d for absorbing the momentum of the carriage as it enters, and a buffer spring e is fixed either on the end of the chamber, when this is closed, or in the side of the table Z, as shown at fig. 4, for finally stopping the carriage. As a carriage enters one of the chambers H the set is slid to the one side or the other of the circuit tubes so as to bring another empty one in front of the tube for receiving the next carriage, while the chamber containing the carriage just received is brought in front of one of the apertures f_1 in the sloping side of the table, through which the carriage is pushed out of the chamber by means of a rod g worked by a lever and introduced through a hole in the other side of the table, as indicated at fig. 3.

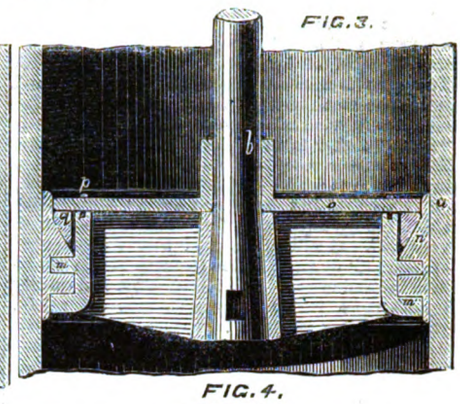
For dispatching the carriages from the central station, each circuit is provided with double dispatching chambers k^1 k^1 k^2 k^2 k^3 k^3 separated from each other and from their respective circuits by valves h^1 h^2 i^1 i^2 j_1 j_2, so that when a carriage is introduced, say, into k^1, the valve h^1 is opened so as to allow it to pass into k^1, after which the valve h^1 is closed and opened so as to allow the carriage to enter the circuit tube, and to be propelled along the same by the current of air entering through the perforations a^1. The opening of the one valve and the closing of the other may be effected simultaneously by an arrangement of levers. The carriages employed for transmitting the dispatches or parcels are made cylindrical in form, and are so arranged that they can be opened for the introduction of dispatches, letters, or parcels, and they are provided in front and behind either with a pair of wheels at right angles to each other, each wheel being nearly of the internal diameter of the tube itself, or they are provided with cylindrical brushes fitting the tube. The body of the piston or cylinder need not touch the internal surface of the tube, because the friction produced by the wheels or brushes is so slight as to render a close fit unnecessary.

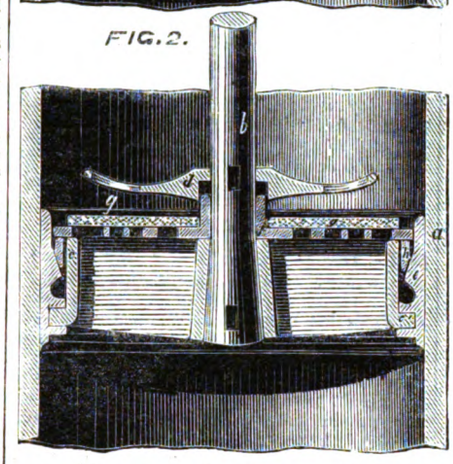
At figs. 6 and 7 of the engraving is shown the construction of the carriages. At fig. 6 the carriage is composed of a light metallic cylinder l fixed at one end into a socket m, and provided at the other end with are movable cover n secured by a bayonet joint and spring catch. The socket m and cover n have projecting rods o p upon which are placed the cylindrical brushes q r fitting the interior of the circuit tube A. The carriage at fig. 7 is of similar construction, but in place of the brushes the socket m and cover n each carry by means of the framing o p two wheels s s^1 t t^1 at right angles to each other and slightly less in diameter than the diameter of the tube A. For introducing or removing the letters or dispatches the cover n is removed.

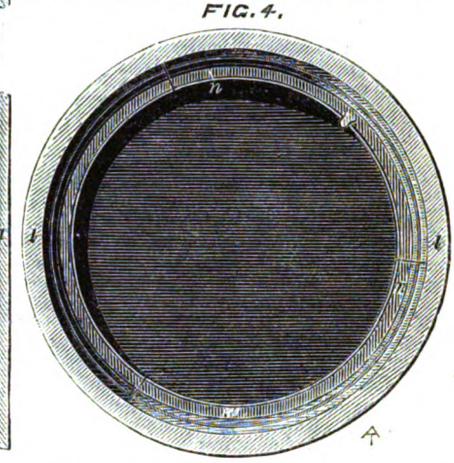
NEW SYSTEM OF PUMP BUCKETS.

BY MR. JACOB BIRD.









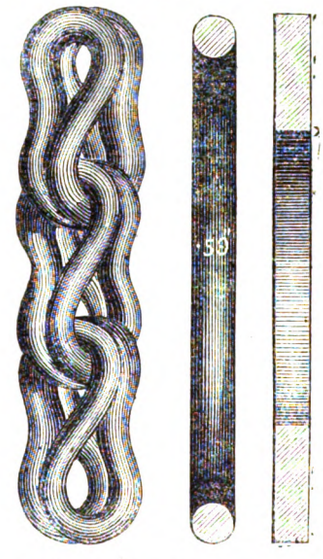
THE main object of the invention which we illustrate in the annexed engraving, is to provide a metallic bucket or piston for single-acting pumps which shall expand and fit tight against the inner surface of the cylinder in the up stroke, and contract in the down stroke so as then to work with a minimum of friction. The invention has been patented by Mr. Jacob Bird. Figs. 1 and 2 of our engraving are vertical sections of buckets and portions of pump barrels; a pump barrel; b bucket or piston rod; c bucket frame or piston formed with radial arms in the usual manner; d valve guard; e bucket ring fitted over the feather c^1; f perforated valve plate or seating; and g the india-rubber or other flexible valve; h expansion split ring secured to e; i spiral springs to assist in lifting f g and h, so as to allow the bucket to collapse during the down or return stroke; in ordinary cases in practice these springs can be dispensed with; j a packing piece or pieces encircling h and part of c.

In both figures the bucket is represented in the up stroke and consequently fitting tightly against a. The space between d and f represents the distance f, and the parts thereto connected are at liberty to travel on the boss of the guard plate or on the rod, so as to allow the bucket to collapse for and during the down stroke, so as to reduce friction. In fig. 1 j are used formed in three segments, although they can be made in one piece, but in fig. 2 c is made deeper so as to provide larger depth of wearing surface than has been used hitherto; k in fig. 1 represents the ring fastened to f, which by its being fitted to slide over c, or it can be made to slide into a groove in c, serves to form a valve should any solid substance prevent g from reaching its seating f In fig. 2 k is not used. The packing here shown can be easily applied to buckets now in use.

In figs. 3 and 4, which are respectively views in vertical section and plan of a lifting or forcing pump, l is the pump barrel; m the bucket frame; n the split bucket ring fitting into the groove m^1 formed in m; o is a cover secured to m by screws p, which when tightened up, forces the expansion ring or piece q against n, and causes it to fit tightly against l. In this arrangement, which is particularly suitable for double-acting pumps, no part of the bucket is free to slide or move up and down on the rod r or on the boss of the bucket.

WELDLESS CHAIN.

AN exceedingly simple method of making chains without welding the links has recently been patented in France, and of which Messrs. Chapman and Boyle, of John-street, Adelphi, are the English concessionaires. The sample from which



our engraving has been taken was manufactured by taking a disc of the diameter of the flat ring, shown in the cut, and punching a hole in it, so as to leave the ring, just as washers are made. It then measures 5·5in. in length, ·51in. in thick-

Digitized by Google

ness, the hole being 3·62in. in diameter, leaving the metal of the ring ·94in. broad. This ring is then rolled by spinning it on outside rolls till it acquires the round bar section—·59in. in diameter—shown in the next figure, by which process also the direction of lamination or fibre is modified. The ring is then drawn out into a long loop, and interlocked with others, as in the engraving. The chain so formed is particularly flexible, though it "kinks" rather more readily than ordinary chains. This, however, may be avoided by a slight change in the form to which the links are set. A length of this chain has been laid down in the Seine steam towage navigation, and answers the purpose very well. It will be observed that the strength of each link depends on the strength of two members instead of one, in which—section and quality equal—there is an advantage in point of safety, just as there is in a wire rope composed of strands over a single bar of a section equal to the aggregate of the strands. The invention is one of promise, especially with regard to steel cables, to the manufacture of which the necessity for a weld has always been an insuperable objection. We believe this method of making chains was patented in England several years since.

THE HOOSAC TUNNEL.

SOME two years since we gave a lengthy description of the works of the Hoosac Mountain Tunnel in America. The object of this enterprise is to reduce the distance between the eastern terminus of the Erie Canal and tide-water at Boston. Since we wrote considerable progress has been made in these important works. In fact, during the past year, and especially during the past five months, much greater progress has been made than ever before upon the work. We take from the report of Mr. A. Beardsley, C.E., the assistant engineer on the works, the following particulars, which will doubtless prove interesting to our readers. We will first take the distances to the various points where the work is being prosecuted:—

Distance from east end to central shaft...	12,837·294	feet.
„ „ central shaft to west shaft... ...	9,747·072	„
„ „ west shaft to now shaft...	265·000	„
„ „ new shaft to well No 4....	659·150	„
„ „ well No. 4 to pier	1,522·825	„
„ „ east end to pier ...	25,031·825	„

The following are the lengths of the headings at the various points of the work, December 2, 1867:—

Length of east end heading	4,608·000	feet.
„ „ west shaft, east heading...	1,262·000	„
„ „ „ „ west heading	611·000	„
„ „ west end heading	617·000	„
Total length of headings	7,098·000	„
Leaving	...17,933·341	„

or 3·396 miles of heading yet to be made, of which 1,218·975ft. are between the west end and the west shaft, and 16,714·366ft. between the west shaft and east end of the tunnel. The central shaft is down 583ft., and well No. 4 is down 150ft. The progress for the month of November, 1867, was as follows:—

East end heading...	126·00	feet.
West shaft, east heading	33·00	„
„ „ west heading	5·00	„
West end	20·00	„
Total for the month of November ...	184·00	„

Thfrty feot of brick arch were completed during the month at the west end, making a total of 516ft. of brick arch completed to date.

The progress for the last six months has been as follows:—

East end	711·00	feet
West shaft, east heading	216·00	„
„ „ west heading	288·00	„
West end	180·00	„
Total, from June 1 to Dec. 2 ...	...1,395·00	„
„ for the previous six months...	632·00	„
„ „ „ year ending Dec. 2, 1867...	...2,027·00	„

The new shaft has been sunk, and at its foot are the pumps which, together with those at the west shaft, are now throwing out between 900 and 1,000 gallons of water per minute. During the last month great quantities of water were struck at both headings of the west shaft (70 gallons per minute at the east heading in one day), and the work was stopped in consequence, which accounts for the small progress at this point. Well No. 4 is an artesian well, which is now being carried down as a shaft to afford two more faces to work from. Its depth will be, when finished, 215ft., its dimensions 8ft. by 8ft.

Mr. Beardsley reports that at the rate of progress for the past year it will require but eight years and ten months to pierce through the mountain, and at the rate for the past six months it will require but six years and five months. But when the central shaft and well No. 4 are sunk to grade the number of faces to work from will be doubled, and the time of completion thereby greatly diminished. At present, drilling machines are employed only at the east end, but in a few weeks they will be used at the west shaft, and also at the central shaft as soon as the buildings and machinery are again in place, and this again will hasten the completion of the work. At the west shaft buildings are already erected for the manufacture of nitro-glycerine, and the use of this powerful explosive will be adopted. Every means that will hasten the work will be employed, and Mr. Beardsley anticipates that within seven years, trains loaded with freights and passengers will pass and repass through the great heart of the Hoosac Mountain as an hourly occurrence.

CONCRETE STONE FOUNTAIN.

THE company which is now carrying out, on a large scale, at East Greenwich, the invention perfected, after so much patient labour, by Mr. Frederick Ransome, have recently sent out to Hong Kong for the public garden there a very handsome fountain made of the patent concrete stone produced by the company. The fountain is about 18ft. in height, and of about the same dimensions in internal diameter. It has ground, middle, and top basins. The ground basin is a quarterfoil, with square projections, it faces enriched by panels with a scroll ornament. The middle basin is also a quarterfoil supported on four columns round a central pier. The shaft is a pointed quarterfoil with tufts of ferns at its base. The cap is formed of a collection of water plants enriched on the under side with models of shells and leaves of water plants. The water from the jet falls into this basin. There are also jets in the middle and lower basins; the four in the lower flash off the water in a smooth uniform sheet without splashing. All the ornaments which are profusely introduced are designed from wild or cultivated water plants—beautifully sharp in their outlines, and true to nature in the curves. The fountain, which is to Government order, was designed by Mr. Thomas Blashill, to whom and the manufacturers much credit is due for this chaste and elaborate work.

DR. LIVINGSTONE.

WE are glad to observe that circumstances continue to strengthen our hopes for the safety of this eminent explorer. Mr. Reuter has just received the following telegram from Alexandria, dated yesterday:—"Zanzibar, Dec. 1.—Intelligence from Keelwa states that Dr. Livingstone, or a person resembling him, was seen travelling towards the west of Lake Tanganyika." In transmitting it to the press Mr. Reuter observes that although the news is similar to that already published by Her Majesty's Government on the 22d of November last, the date of the above message is Zanzibar, December 1. Supposing the latter date is correct, Dr. Livingstone must have again been seen west of Lake Tanganyika, which increases the hopes of his safety. It must be remembered that the Lake Tanganyika is upwards of 300 miles long.

NEW GRAVING DOCK FOR GLASGOW.

AT a meeting of Clyde Trustees held in Glasgow on Tuesday, it was resolved to ask for borrowing powers to the extent of £600,000 in the Bill for the formation of a new graving dock which the trustees intend to bring before Parliament. The new dock is to be 500ft. long, 100ft. wide, and 30ft. deep. The width at the entrance-gate will be 83ft., and the depth 20ft. 6in. at spring, and 19ft. 6in. at neap tides. The cost of the ground is estimated at £86,000. The unexhausted borrowing powers of the trust amount to £236,000, and coupling with this the £600,000 asked for in the Bill, there will be created a capital of £836,000 with which to undertake and complete the erection of the graving dock and other necessary works in the river and harbour. From the annual report of the harbour-master it appears that during last year there were 49 steamers built and engined on the Clyde, having an aggregate tonnage of 20,327, as compared with 64 steamers and an aggregate tonnage of 28,548 in 1866, the decrease in 1867 being 15 vessels and 8,221 tons.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE fifteenth annual meeting of members of this society took place on the 4th inst., at its rooms, Aldermanbury. The auditors presented their report and the balance-sheet for the past year. Both documents were of a highly satisfactory nature. The number of ordinary and honorary members on the books is 163, and the funds invested for all purposes £1,264 10s. After the reception of these papers by the meeting, the president, Mr. Joseph Newton, proceeded to deliver his annual address. He reviewed at much length the progress of mechanical engineering at home and abroad during 1867, and contrasted the educational machinery of the Continent with that of this country. The comparison was not flattering to our national pride, and it went to account for the superiority of foreign workmen in certain branches of manufacturing industry over those of Great Britain. The evil was patent, and the remedy should be speedily applied. Comprehensive systems of technical schools for each branch of science and art must be established forthwith. Defective legislation had impeded national progress, at all events in regard to manufacturing industry, and we had now to cure a disease which ought never to have existed. If it were possible to estimate the value of the waste brains of this kingdom as the average of waste land has been measured, we should be appalled by its magnitude. Waste brain, like waste land, brought forth weeds; and these were seen in the form of idleness and criminality. Had the soil been fertilized, the flowers and fruits of industry would have flourished upon it. After an energetic appeal to the associated foremen to persevere in their own especial studies and pursuits, Mr. Newton concluded his address, and, in accordance with rule, resigned his office. His re-election, however, followed immediately, on the motion of Mr. Keyte. After completing the arrangements for the establishment of a widow and orphans' fund, and appointing the date (15th February) for the anniversary festival of the society, the members separated.

PROGRESS OF THE HARTLEY INSTITUTION.

WE congratulate the Council of the Hartley Institution upon the establishment of classes for engineering students. This important and thoroughly progressive step has resulted from an offer for that purpose, which was made by several gentlemen. The Town Council of Southampton unanimously adopted this offer, and it will be seen from our advertisement columns that arrangements have been made for commencing the classes without delay. The numerous resources of an engineering character which Southampton possesses, as well in her large steam fleet as in the factories connected with it, and in the important engineering works which are being carried on in connection with the borough, cannot fail to show that it offers unusual advantages to the engineering student for acquiring a practical acquaintance with every branch of his profession. Besides these special classes, the Hartley Institute will afford a thorough course of scientific instruction, which will be carried on by gentlemen in every way qualified for the task. We thus anticipate for the future engineering school of Southampton a high reputation; and we are glad to find, amidst so much talk about technical education, that something practical is here being done.

THE First Commissioner of Works has decided on increasing the bathing lake in Victoria Park to nearly double its present size. The works will be commenced immediately, and following the best precedents of the public works carried on in Lancashire during the cotton distress, will be done by task work. In this way, while employment will be given to many in the east of London willing, but at this time unable, to find work, a permanent public improvement will be effected with economy and despatch.

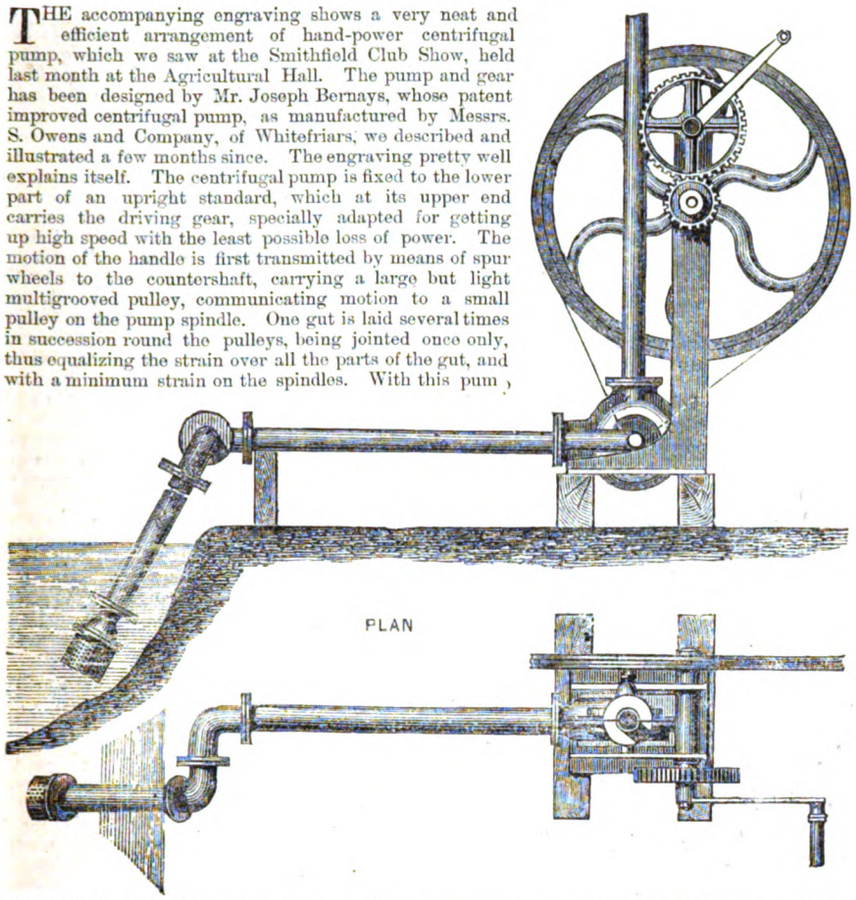
HAND-POWER CENTRIFUGAL PUMP.

BY MR. JOSEPH BERNAYS.

THE accompanying engraving shows a very neat and efficient arrangement of hand-power centrifugal pump, which we saw at the Smithfield Club Show, held last month at the Agricultural Hall. The pump and gear has been designed by Mr. Joseph Bernays, whose patent improved centrifugal pump, as manufactured by Messrs. S. Owens and Company, of Whitefriars, we described and illustrated a few months since. The engraving pretty well explains itself. The centrifugal pump is fixed to the lower part of an upright standard, which at its upper end carries the driving gear, specially adapted for getting up high speed with the least possible loss of power. The motion of the handle is first transmitted by means of spur wheels to the countershaft, carrying a large but light multigrooved pulley, communicating motion to a small pulley on the pump spindle. One gut is laid several times in succession round the pulleys, being jointed once only, thus equalizing the strain over all the parts of the gut, and with a minimum strain on the spindles. With this pump one man is enabled to raise sixteen gallons per minute to a height of 20ft. In some of the arrangements of this pump, the handle is dispensed with, and a pair of strap pulleys are put in its place, which enables the pump to be worked from any existing shafting. In the latter case, and if desired, the dimensions of the pump are altered so as to give either more water, or to raise it to greater height than stated above.



VOLCANIC ERUPTIONS IN CENTRAL AMERICA.

THE citizens of Leon, Nicaragua, have recently been startled by the sudden and almost simultaneous breaking out of a number of volcanic vents on the Western or Pacific slope, near the base of the long extinct twin volcano of Rota, the middle one of the chain of volcanic cones which follow each other in close succession from the northern extremity of the Lake of Managua to the Volcan el Viejo, the most prominent of either, and a landmark for strangers desiring to enter the port of Realejo. The first intimation of the eruption to the inhabitants of Leon, only ten miles distant in a direct line from the scene of the eruption, was a low rumbling sound like distant thunder, shortly followed by quick, sharp, and continuous reports, resembling the roar of a not far distant battery of heavy artillery. On one particular night two large volcanic fires, with several smaller ones scattered about on the plain, shed their lights on the surrounding country, and even lit up with a warm glow the towers of the cathedral in the plaza of Leon. The eruptive matter consists only of large masses of molten lava, scoria, and ashes, unaccompanied by any lava stream. The latest information states that a cone of about 20ft. of elevation had been formed round the principal orifice, but whether caused by upheaval or by the deposition of scoria and ashes was not stated.

MALTA WATER SUPPLY.

THE late prolonged drought at Malta induced the Government to make extensive explorations for water in different parts of the island, especially in the sandstone at the Marsa Valley, and in the marly districts beyond the ancient city of Medina, now called Citta Vecchia. These experiments have been attended with a very considerable amount of success. Numerous shafts have been sunk at the Marsa, which already yields upwards of 400,000 gallons a day, and it is calculated that the whole supply from these sources will be upwards of 900,000 gallons a day, or more than double that given by the two principal aqueducts, upon which the cities before chiefly depended. For the purpose of boring through the rock, and exploring laterally from the sides of the shafts, a boring apparatus, which will cost £240, has been ordered from England. With reference to the important discoveries of water made in the marl on the other side of the Citta Vecchia hill, the exact quantity they will afford has not been yet ascertained, but it is confidently believed they will double the supply at present obtained from the Wignacourt and Fanara aqueducts.

LOCOMOTIVES IN THEIR DAILY WORKINGS.

THE locomotive rushing along at a speed of 20, 40, 60 miles an hour, is practically a huge projectile, and is subject to exactly the same laws as a cannon-shot; the damage it does is by concussion upon the rails, the force of which is divided between the permanent—or in another sense unpermanent—way and itself. This force, like that of the cannon-shot, is estimable as the weight of the body multiplied by the square of its velocity, and the blow which the oscillations of an engine cause to be given to the rails are comparable with the impact of a rifle bolt upon an iron target. In gunnery practice the tests are generally applied direct, in railway battering the blows are indirect. The gun-shot hitting on an incline does not penetrate, but makes a more or less deep scoop, and travels on deflected from its former course. The blow is just as hard whether the thing that gives it has travelled 60 miles, 60 yards, or 1-60th of an inch, the actual force of impact is always given by the actual velocity of the moving body at the instant of collision. Every vertical oscillation, every lateral oscillation of a locomotive then is calculated to make the engine hit the rails with a terrible force equalling, or exceeding the tremendous blows of the largest steam hammers. Every oscillation, then, means destruction—every jolt and jar that the passenger feels means damage done to rail and engine, means so much loss to shareholders. If the blows due to velocity of impact were given direct, the rails might be often smashed outright, but the main weight of the locomotive is borne on springs, and carried on wheels. This, however, only modifies the evil, it does not get rid of it. The momentum is still there, and when the blow is given, although much of the violence is taken off by the springs, yet those springs give off again the force they have absorbed, and thus, although a smash is avoided, the full force of that smashing power is only distributed over such a sufficient amount of area or length of road as shall be capable of enduring it without giving way, but still, not without sustaining a considerable percentage of injury. The oscillation of the boiler is evidently thus one source of destruction, and every vibration of the springs is mischievous. For the normal load of an engine upon its wheels, ten tons upon each axle are what is generally allowed in locomotives as at present constructed, and the deflection of a bare 1-4th inch in a spring being (on the average) equal to a load of one ton, a depression by oscillation of 1in. would be equal to an additional weight of over four tons. This extra weight, then, is, by the vibration of the springs, thrown over from side to side of the engine in travelling, gradually diminishing until the vibrations have died out. But as one set of vibrations have not ceased before another set begin, it follows that these vibrations add the equivalent of a permanent useless load upon the engine, the steam power used up in overcoming which might be usefully employed in hauling in an engine made to run perfectly stable. It is also certain that the grind upon the road must be increased by this useless swaying weight, and that bruising of the rails from end to end of the line must be done by it.

The direct force of impact of such an engine as the Stephenson's express shown at Paris travelling respectively at the rates of 7½, 15, 30, and 60 miles an hour (88 feet a second) would be in the proportions of 3,630, 14,520, 58,080, and 232,320 foot tons, less a definite allowance in each case for gravitation, or, as it would become in this case, friction, according to the actual weight of the travelling engine. In railway accidents we never see these terrific forces exerted; steam is shut off, and suction in the cylinder induced, and brakes are put on; or the blow is indirect; or the buffer-springs yield; or in some way or other the momentum is seriously diminished before actual collision takes place. Now, we do not contend for a moment that every oscillation absorbs the full amount of impact force, but there is in every oscillation a force taken up out of the momentum in the yielding parts of the engine equal to the balance between the work of locomotion done and the full power of the engine, or, in other words, equal to the amount of resistance or impediments offered. Considering the enormous force contained in the total momentum of a locomotive, every small percentage even that is brought to act upon either rail or engine is a quantity whose capacity for evil needs the closest consideration from engineers; and especially as the various actions of momentum are the main source of damage to engine and rail alike, and therefore the main cause of the heavy expenses of working locomotives, and which, it is well known, now costs about 22 per cent. or nearly a quarter of the gross receipts of every line. This question of damage done by neglect of steadiness in the engine—or, in other words, the cost of permitting this waste of momentum, which ought all to be employed in drawing the train, and instead goes into destruction of rails and wear and tear of engine—is one which ought to be thoroughly understood by shareholders. It is the main cause of ruin to them. Another lesson obviously comes out of the same consideration, namely, that light engines and high speeds are suitable for express trains, whilst heavy engines and slow speeds are right for heavy loads, or, in other words, great tractive power is the proper thing for goods traffic and long passenger trains. Hence, too, we see in these rough calculations of the accelerated rates of momentum gained by speeds how it is that express trains are so destructive to the roads; and one can very well understand how the practical effects discovered in railway management should have produced two schools of engineers, one advocating light loads and quickly succeeding dispatches of trains, the other long trains at long intervals carried at slow speeds; the one thinking the fetch-and-carry system best, the other the drag-along system the most economic. A due study of the destructive action of the wasted momentum now transferred into oscillations, concussions, bruises, and friction by practical locomotive engineers will in all probability give the public the advantage of two classes of engines equally able to ply upon the

Digitized by Google

same road, and equally innocuous to the permanent way; but to obtain this, steadiness of the engine must be first looked to.

The question of steadiness leads at once to the consideration of how the frame and boiler are set upon the wheels—the boiler being the main mass of the engine. Set upon a pair of leading and a pair of trailing wheels, with axles rigid, except in a small amount of direct vertical play, and with large driving wheels in the centre of the frame, the highest forward speed compatible with the present fashionable systems of construction may be obtained; but the capability of turning sharp curves is limited in exact proportion to the length of wheel base—a long engine like a long dog cannot run round in a small space, and short engines cannot have effective furnaces, without which effective motive power cannot be got. This difficulty bifurcates in existing locomotives in two distinct directions—long engines and coupled wheels. A long engine must be set upon a short wheel-base, or it will not turn curves; a long engine on a short wheel-base must have a lot of overhang, and must therefore be a jumpy one in the direction of its onward motion. If set upon three sets of wheels, the tendency to longitudinal oscillation must be facilitated, because if the centre one be a trifle too large—and can it ever be a trifle too small?—the body of the engine will swing upon this fulcrum like the scale beam in its hanger. Even if the adjustments be made on perfect planes in the workshop, be as exquisite as the best of Stephenson's best work, there is not a yard of any railway that is absolutely level, and a hummocky rail will form a fulcrum for an engine to sway upon as well as the axle of a wheel. It is even worse, because the fulcrum being on one side, the throw of the engine will be diagonal and not direct. In the like manner, the coupling of driving wheels stiffens either the whole or a large portion of the rolling gear, and the bracing of wheels together not only seriously increases friction in the proportion of the square of the number of parts coupled, but the coupling up of numbers of wheels acts against the separate play of the springs, and by increasing the rigidity of the machine accelerates the destructive action of oscillation in running, in proportion as a sledge hammer blow character is given to the concussions. Our present six-wheel coupled goods engines, with their enormous size and weight, must batter the roads fearfully in direct travelling if the wheel-base be short, and, if long, the lateral oscillations will be as great in their forward effects as the vertical ones with the short base; added to which the grind and friction must be enormous in passing curves. Now, nothing runs so easy as a thing upon four wheels, especially if the thing carried be, like a carriage, borne upon two points. If, then, we must have engines, which, for the sake of tractive power, or for any other reason, must have more than four wheels, the number of wheels employed should be divided into two portions, and the bearings of each portion combined at one point; the boiler, or greatest mass of the engine, should then have free play upon these two points—in fact, should be pivoted on the bearings of the leading and trailing sets of driving wheels.

It is evident that if an engine run upon four wheels the whole number of wheels must always be in contact with the rails, and even if the engine were fixed together perfectly rigid, and the wheels without springs, there could be neither longitudinal nor lateral free lift of the wheels away from the rails. With a properly supported and properly balanced engine, therefore, although the permanent way was up and down, like the waves of the sea, there could be no sledge hammer batter, and all the oscillations of the boiler on the springs of the wheels could only transfer the amounts of arrested momentum into additional weight brought upon the springs, and consequently grind upon the road. But the very pivoting of the greatest mass of the engine upon two points would give steadiness by its influence in preserving the centre of gravity of the boiler or principal mass from being disturbed. Another equally important object would also be thus gained, the utmost facility of passing the sharpest curves without grind against the rails; for the two spindles fitted to each end of the frame which supports the boiler, on which the bogies would pivot, would be, in fact, practically two engines, and the connecting link or boiler frame would act as a rope or rod to pull the wheels of the leading bogie inwards from the outer rail, against which its natural tendency would be to grind; in the same manner the drag of the train itself would exert the like useful influence on the trailing bogie. And the value of this curbing of the centrifrugal force of the locomotive being inherently structural, will be always in exact degree to the requirements of the occasion, and will be always in effect at the right moment of time. In this way there would be the most ready adaptation of the sets of wheels at either end of the curves, and engines so made would be able to pass the sharpest ever put down on any line as yet constructed, at high speed, without danger. It will thus be seen that we distinctly prefer eight-wheeled engines, with the wheels coupled in two sets of four each, to any six-wheeled coupled engines which have been, or it is at all probable, can ever be designed. We have no objection to 12-wheeled engines, if the wheels are coupled in sets of six, each set presenting the smallest practicable wheel-base, and respectively attached to freely-moving leading and trailing bogies, pivoting under each end of the boiler; each set also having its own pair of steam cylinders.

There is another important matter to which shareholders should give attention—tenders. The duty of a locomotive is to pull trains of goods or passengers; and its capability of pulling is exactly estimable by its weight and speed. It is the momentum that does the motive work, and this momentum is the weight of the engine multiplied by its velocity. With great steam power great momentum may be worked up in a light weight by extreme velocity, and excessive speed obtained; but the train-load must be light, because without weight of engine there is not sufficient bite upon the rail to draw, or in other words, the gravitation of the engine is overcome, and the wheels slip. It is to prevent this slip that engineers have introduced coupled driving wheels. They put them on to passenger engines to get grip in going up inclines; they put them on to goods engines to get tractive power for hauling so many more tons of coals, stone, or merchandise. Now the tenders are so many tons weight hauled about to no purpose whatever; in short, the tender is not only a hindrance but a drawback, whilst the fuel and water it has to carry would be doing additional momentum if put upon the engine, doing in other words so much more hauling of goods or passengers along the line at no additional cost whatever. No excessive weight need be put upon the wheels in consequence of the fuel load on the engine; for if to an eight-wheeled one the four wheels of the tender were added, forming a twelve-wheeled engine with two sets of six wheels coupled, the weights upon each axle might be even diminished, while the whole tractive power would be increased directly by the, say, ten tons of coke and water, and indirectly by the getting quit of at least ten tons of load to haul in the abandonment of the useless tender itself. Still, further, another subject comes up in these considerations, which is briefly this. That if, under the adoption of the views we have advocated it be found necessary, as it undoubtedly would be, to lengthen the boiler, this lengthening would not be detrimental to the running of the engine, the wear of the road, nor the passing of curves, whilst the advantages would be greater generation of steam, and less liability of burning the fire-box or tubes in the boiler.

The direct advantages to be looked for in the improved locomotive of the future are:—That it should carry its own fuel and water, increasing thereby its hauling power without any additional expense whatever; that in so doing the weight of the engine would be better distributed over the wheels by the coupling of separate sets connected with separate leading and trailing platforms, upon the centre of which the boiler should rest, longitudinal and lateral oscillation and grind in passing curves being thus reduced to a minimum, and the present excessive wear and tear of engine and permanent way being at the same time as much as possible prevented. The incidental advantages would be:—No tenders to construct and maintain; no turn-tables to build, as such engines could run either way; less necessity in making lines of road, of reducing inclines approaching to levels; less expense in maintaining the permanent way; less interruption and less danger to the traffic in consequence of less frequency of repairs of road; less cost of maintenance of engine; and a general reduction of expenses throughout the whole of the rolling-stock and factory departments.

There was a model and plans of what seems to be such a desirable engine in the Paris Exhibition—Mr. Fairlie's. But nobody noticed them, not even those particular eminent men who have written letters to the "Times," and had letters printed in the government report, giving their own—fortunately not the general—opinion of the advances of foreigners, and the necessity of introducing continental schools into England for the education of English engineers. The eminent foreigners who instructed them on the superior (?) abilities of foreign mechanics would not have been likely to have asked their polite attention to an Englishman's plan: though possibly at some future international exhibition we may see a French Prussian, or Belgian engine in the aspect of continental modifications of it, and we may expect that the Playfairs of that day will then appreciate, after the explanations of their foreign friends, its especial excellences and merits. We should regret very much being obliged to pass over the numerous models and plans shown at Paris if we thought there was anything amongst them at all approaching Mr. Fairlie's in merit. One plan by M. Thouvenot was very like it. We do not know which was first in the field, but that is little matter, as the two plans are essentially different, that shown by M. Thouvenot being impracticable—leaving out of the question the Fell complication—while Mr. Fairlie's is thoroughly practical in all its details, and, what is more, is actually at work, and therefore not problematical. M. Thouvenot's plan is still only on paper. A Fairlie engine was constructed and successfully run, in 1865, upon the Neath and Brecon Line, during the construction of which it passed curves of 2¼ chains radius at the rate of 12 miles an hour, and to this exploit Captain Tyler has given the highest encomium, after personal experience. That gentlemen has again during the present month testified to the value and advantages of the Fairlie system, in his Report upon the Condition and Prospects of the Grand Trunk Railway of Canada. We had taken our notes of the Paris model before we knew what opinion Captain Tyler retained, and indeed, as the date will show, at that time the report we have alluded to was unpublished. It is gratifying, however, to find these views so strongly supported by one so able and so experienced in railway construction and management.

The sum total of all we have to say about the Fairlie engine may be briefly enough put. It is calculated to save wear and tear of line, to haul more load at much less cost, to possess more steadiness and safety in running, to yield by its savings a considerable dividend to shareholders, to double the carrying power of every railway in the kingdom, and to reduce station expenses by doing away with costly turntables and their sites. Finally, whether the Fairlie plan or any other plan in existence, or not yet in being, shall hereafter come into general practice, the point we have had at heart in these elaborate essays will have been fully attained if we can get shareholders themselves to go into the consideration of the savings to be effected by improvements in the designs of locomotives. Raising additional capital in any way must increase existing burdens; and although in some cases to capitalise floating debts may be productive of temporary and even substantial benefit, yet no permanent relief from difficulties can be afforded by any other means than increased earnings upon the lines themselves. All modifications of capital arrangements can be but shuffling the conditions like the shuffling of cards, the pack of real evils remaining constantly the same. To make the engines of every line save in their daily working a dividend upon the outlaid capital is the one requirement to bring existing railways, despite their enormous debts, again into a healthy and prosperous state.

[The foregoing remarks are upon an important subject, and are well worthy the attention of engineers and the public at the present time when railways are taxing the energies of officials to keep them going. The article is one of a series upon Locomotives and Railway Dividends now appearing in the "Standard," and which contain some wholesome truths and sound advice.]

THE "Cronique des Arts" tells a curious story which shows to what perfection the art of manufacturing antiquities has attained in Italy. In 1864 M. de Nolivos, a French art collector, bought at Florence a bust of Girolamo Benivieni. It was exhibited in the following year in Paris, where it was pronounced by connoisseurs to be the work of either Mino da Fiesole or Benedetto da Majano (1490-1510). M. de Nolivos' collection was sold by auction in Paris last year when the bust was secured by Government at a large price for the Louvre. It now appears that the bust was the work of a living artist, Giovanni Freppa, residing at Florence. This statement is supported by certificates from Freppa himself, from a sculptor of Florence who saw him model the bust, and from a workman in a tobacco manufactory, who declares the bust to be an excellent likeness of a comrade who sat to the sculptor as his model.

Obituary.

WE regret to announce the sudden death of Mr. Claudet, the veteran photographer and distinguished artist. Among the earliest and most successful followers of Daguerre, Mr. Claudet was almost the last to abandon the use of metal plates for the more modern and improved processes of photography, and it was in some degree due to his skill and knowledge that daguerreotype at first made such progress in this country, while the inventor's own countrymen were as eagerly bent upon developing the new art in the direction traced by our Fox Talbot. Mr. Claudet's nice discrimination and manipulative dexterity gave to the productions of his camera an extraordinary refinement. He was a Fellow of the Royal Society and other learned bodies.

Correspondence.

ON DEFENSIVE MEASURES AGAINST HURRICANES.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—We ought to bear in mind that the West Indies and Central America are most probably as yet in an embryo state as regards their commercial, political, and military importance. In a few years hence the main current of a vast world traffic will have to pass through those regions, and then the Central American isthmus will have been bridged over by numerous railways, and may possibly, also, be traversed by a ship canal. Increased facilities of transit across that isthmus will, in their turn, tend to stimulate industrial and commercial enterprise on the Pacific coasts; and whether or not the increasing growth of volcanic and coralline reefs* and islands in Oceania may in the course of time cause such a deviation of sea currents as at some future time to render milder the climate of the northernmost parts of the Pacific coasts, there can remain little doubt but that the vast traffic, with the growing communities of the west coast of America, of Oceania, Australia, and the Asiatic coasts, will pass *via* the West Indies. Hence a discussion of defensive measures against the ravages of hurricanes can do no harm, and may result in the devising of further efficient and practical measures for the protection of life and property. With this view I beg to submit to you some diagrams, illustrative of a system of dwelling-houses, stores, arsenals, &c., which I consider especially applicable for hilly countries, exposed to violent hurricanes; and, also, of a framework structure, consisting of iron, which may be, in combination with wooden beams, wire ropes, chains, &c. (just as the constructing engineer may deem best), which framework or "hurricane-frame," if erected across the lower ridges, valleys, plains—in fact, across any parts along which the hurricanes are known to sweep with intensified violence, would act as a fitter and local mollifier or "brake" to the hurricane, and thus afford great protection to the warehouses, wharves, docks, harbour, and ships which lie to the leeward of such a hurricane frame, against the most violent hurricanes. The houses, stores, &c., are to be arranged along, and partly excavated in, the sides of the hills, so as to expose as little surface as possible to the force of the hurricane—the streets passing along the fronts of the houses, and ascending the hill in gentle inclines, other inclines and stairs connecting directly the various terraces at right angles.

The diagrams are all sections, made only to roughly indicate the nature of my propositions. In fig. 1, *a a* are sections of the terrace buildings; *b*, section across the street; *c*, drains for leading off the rainwater;† *d*, balustrade walls lining the streets, built with an unusually broad base, so as to resist better the pressure of the hurricane; *e*, railings on the top of such walls; *f*, the natural rock composing the hill. I am under the impression that if the towns of the West Indies, in any localities not protected by the hurricane frames I am about to describe, were laid out in a manner similar to what I have indicated, they would effectually resist the most violent hurricane. The line *h h* in those sections indicate that the horizontal distance between the respective terraces might be greater, and that between the parts of the slopes *g*—gardens, plantations, &c., may be arranged. In the same manner, in section, fig. 2, the protected terra firma space *b b* may be larger, as that section indicates.

Fig. 3 is the section of a hurricane proof lighthouse of masonry, and it may interest some of your readers to be informed that this shape of a broad-based conical lighthouse suggested itself to my mind in December, 1858, when on board the Royal Mail Steamer "Atrato," then commanded by Captain Woolley, whose tall figure and kindly countenance I fancy I see before me now (he perished during the late hurricane, in the "Rhone," off Peter Island). I need not waste your space with a

FIG. 1.

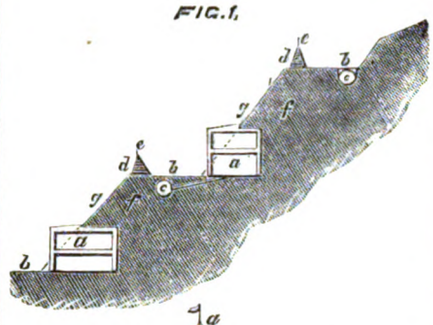

FIG. 2.

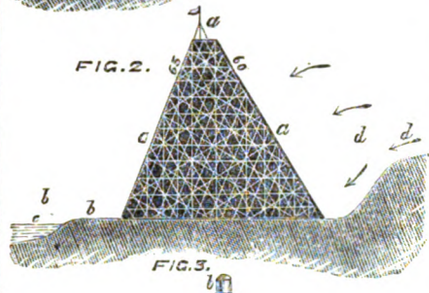

FIG. 3.

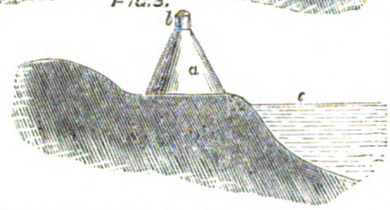


detail description of the hurricane frame, of which a section is shown in fig. 2, because the details of its construction are dependent on local features and resources, and have to be left to the discretion of the constructing engineer, its width, its height, and length, having, of course, to be determined by the area of land and harbour surface it is destined to protect. In fig. 2, *d* indicates the space to the windward of the hurricane frame, the arrows pointing the direction of the hurricane. Let your readers call to mind the Crystal Palace in Sydenham, minus the glass, and with the iron framework much stronger, by means of additional diagonals and girders, and they will then be able to realize the construction of my hurricane brake.—I am, Sir, yours, &c.,

GUSTAV JULIUS GUNTHER.

London, December 31, 1867.

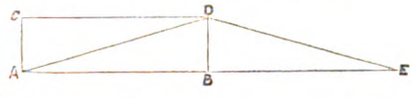
* It is well known that the Torres Straits are being closed up by that growth; and Professor Richter predicts that when the Florida peninsula will have annexed the Bahamas—thus, of course, stopping the Gulf Stream—the northermal line of perennial ice now passing near "Cape Farewell," will probably have to be shifted down to the Lizard or Cape Lao Vicente. Let us hope that that period—when Macaulay's New Zealander will look for walruses at the mouth of the Jajo—be as yet a few thousand years ahead of us.

† Travelling and residing many years in the torrid zone has almost convinced me that a great many diseases, fevers, &c., could be prevented if all non-liquid wastes were at once deodorized by absorption, by means of earth or ashes, &c.; and the invention of the Rev. Mr. ———, of earth-closets, ought to be adopted without delay in all tropical countries. Indeed, in the Old Testament, in the laws of Moses, we find indicated a most profound acquaintance with sanitary science.

SQUARING THE CIRCLE.

LETTER I.

SIR,—Permit me to add a proposition to this interesting discussion. I shall begin by describing a square as two straight parallel lines crossing each other at the shortest distance, and a circle as a line bent parallel to and round a point having an area completely contained, greater in proportion to its circumference than any other figure, and to prove that this area is equal to that contained between two straight parallel lines, the sum of which together is equal to the circumference of the circle, the distance from each other being that of the radius of the circle. Thus, let B D = C D, and together in



length equal the circumference of the circle with D B for its radius. Join C A and B D; the area of fig. A B C D will equal that of the circle; take C D away, and add it to A B, making A B E join A D and E D; the triangle A D E will also equal the area of the circle, and so any intermediate quantity of the line C D taken away and added to A B, and the extremities joined will give a figure, the area of which will be equal to that of the circle.

In my next, I propose to prove the proposition.—I am, Sir, yours, &c.,

JOSEPH A. NICHOLSON.

3, Adelaide-place, London-bridge, E.C.,
January 7.

PETROLEUM AS A FUEL.

SIR,—We have perused with much interest an excellent article in your last issue in which you say, "One concluding suggestion, however, it occurs to us to offer, and that is, that the question of using petroleum as a fuel for generating steam under marine boilers should be practically solved." On this point we may remark that arrangements are now in progress for thoroughly testing, in one of H. M.'s steam launches, the only system by which the perfect combustion of liquid fuel for steam generating purposes has yet been effected. Further on, you say "Field's principle, as applied to Cornish boilers, is perfection, and we believe it would prove equally successful if adapted to marine boilers. And this, notwithstanding the circumstance that the Americans have virtually given its application up as a bad job. The Secretary of the American navy reports that after an elaborate series of experiments, the conclusion arrived at is that the convenience, comfort, health, and safety are against the use of petroleum in steam vessels." Now, in the first place, we beg to observe that the system referred to is known as the Aydon system, patented by Wise, Field, and Aydon. You have, doubtless, been led to infer that it is known as Field's system, from the fact that the first experiments made by the patentees were carried on at the works of Messrs. Field. In the next place, it might be inferred from your observations that this particular system has been tried by the Americans and pronounced a failure. This is not so, because they have never tried it, nor have the patentees as yet been in communication with the American authorities on the subject. We may, however, remark that the Aydon system has been seen in operation and approved of by many of our most eminent scientific gentlemen, and also by gentlemen interested in the American plan, who owned themselves beaten. In conclusion, permit us to state that the fuel used by preference is not petroleum, but merely refuse material, which is perfectly safe, convenient, and cheap (having hitherto been considered a worthless drug in the market), and that by the Aydon system such fuels are perfectly consumed without smoke.—I am, Sir, yours, &c.,

FRANCIS WISE AND CO.

Chandos Chambers, Adelphi, W.C., January 9.

[If Messrs. Wise had read two lines more of our article they could not have drawn the inference they have attempted to draw. We had already spoken favourably of the Field—or rather the Aydon—system, as we were enabled to do from personal observation of its working, and after referring to the American Naval Secretary's report (as quoted above) we especially added, "All we can say is, that they have not gone the right way to work to use it." There is not the shadow of a reason for inferring that the Aydon system has been tried in the American navy and pronounced a failure. We were writing of the use of petroleum as a steam fuel, and not specially of the Aydon method of using it. If our meaning appeared at all ambiguous, it ought to be made clear enough by the Naval Secretary's conclusions, which were "against the use of petroleum in steam vessels," and not against any special system of burning it.—ED. M. M.]

Meetings for the Week.

MON.—Royal Geographical Society.—At 8.30 p.m., papers on "Explorations in the Isthmus of Darien," by M. Lucien de Puyott; and on "The Physical Geography of the Belize River," by T. Cockburn, Esq.

TUES.—The Institution of Civil Engineers.—At 8 p.m., inaugural address of Mr. Charles Hutton Gregory, president, and renewed discussion upon the papers on "The Victoria Bridge," and on New Railways at Battersea, etc.

FRI.—Royal Institution.—At 8 p.m.—Professor Tyndall on "Faraday as a Discoverer."

Royal United Service Institution.—Lecture at 3 p.m., by Captain E. A. Sloane, on "The Utilization of the Soldiers' Unemployed Time, with a Proposed Scheme independent of Government Aid.

ANOTHER remarkable meteor appeared on the morning of New Year's day, at twenty minutes past seven, and was seen in Kent, travelling slowly through the sky from east to west. In diameter it was about eight inches, a globe of fire, followed by a bright light, and leaving a line of white smoke behind it that could be seen for fifteen minutes. The meteor, which was accompanied by a fizzing sound, appeared about 45 deg. above the horizon, traversed more than a third of the heavens, and then burst into three pieces near the earth. This was probably the same meteor as seen at Havre.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10s. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later tqan 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—J. C.—Messrs. E. and Co.—E. W.—Messrs. H. and R.—P. M. P.—S. E.—G. L. W.—R. D.—F. H.—T. E.—P. C.—G. W. H.—J. M.—C. B.—Messrs. C. M. and Co.—J. W.—C. D. A.—G. E. P.—G. J. G.—T. S. T.—W. H. H.—J. B.—F. W.—R. G. S.—S. H.—R. N.—A. M. B.—J. C.—C. F. R.

Naval, Military, and Gunnery Items.

IT is announced that Rear-Admiral Halsted has resigned the secretaryship of Lloyds. It was understood to have been accepted by the committee.

ACCORDING to the report of the Naval Secretary, the American navy has been reduced since last year by 40 vessels, carrying 482 guns, and consists at present of 238 vessels, carrying 1,869 guns o which however, only 103 ships, carrying 898 guns, are in use, the rest being laid up. The *personnel* of the force has not been quite 12,000 men.

SOME iron plates coated with zinc, on Mr. Daft's plan, have been taken out of the water alongside Portsmouth dockyard for examination, after having been submerged for nearly three years. All the nail heads were found to be perfect, and the surface of the zinc, with the exception of a thin deposit of muddy slime, was found to be perfectly clean. They will be partially taken to pieces and further examined and reported upon.

THE Chilian gun now being made at Pittsburgh, U.S., is 22½ feet in length, being two feet longer than the Rodman gun at Fort Hamilton, but of exactly the same bore, twenty inches. Its greatest diameter is 5 feet 4 inches, its least diameter, 2 feet 9 inches. The gun is designed for garrison or naval service.

ON the 31st of December, 1867, 85 ships were building on the Wear. Thirty-three of the number were sold, and 52 unsold. Fifteen of the vessels in course of construction are of iron, five composite, of wood and iron, and the remainder of timber. The largest iron vessel is a steamer of 1,100 tons, and the second in point of tonnage is a composite ship of 1,040 tons. Of the 15 iron vessels in course of construction, nine are screws.

THE entire mercantile navy of Europe, according to the latest statistical returns, consists of 100,000 vessels, representing a total tonnage of 12 millions and employing 600,000 men. This amount of shipping is thus distributed :—Bremen, 294 vessels; Hamburg, 539; Lubeck, 45; Hanover, 906; Mecklenburg Schwerin, 424; Oldenburg, 610; Prussia, 1,443; Austria, 9,491; Belgium, 107; Spain, 4,359; France, 15,259; Greece, 4,452; Holland, 2,227; Italy, 13,223; Portugal, 591; Great Britain, 27,868; Russia, 1,416; Denmark, 2,740; the Elbe Duchies, 2,552; Norway, 5,678; Sweden, 2,236; Turkey, 2,300.

LIEUTENANT-COLONEL Weyde, a Russian officer, has invented an apparatus for throwing light on objects under water. It is not expensive, and experiments made with it by the Russian and Prussian Governments in the sea near Cronstadt, and in the river Spree, are stated to have produced very satisfactory results. A very important use of this invention is, that it enables the officers of a ship of war to discover any submarine mines or torpedoes sunk under it by the enemy. It must, of course, also greatly facilitate the recovery of sunken ships and other objects at the bottom of the sea.

SHIPBUILDING in Scotland, which for the past two years has been much depressed, begins to show renewed vitality; the number of vessels contracted for compares favorably with that of last year. There were built in 1867, 181 iron vessels of 97,500 tons, against 188 of 116,996 tons in 1866, and 229 of 146,700 tons in 1865; and there are now building 113, of 112,360 tons, against 84 of 70,000 tons in 1866, and 152 of 129,700 tons in 1865.

THE American press is devoting some space to the discussion of the "Alabama" claims controversy. Some papers allege that Secretary Seward's unskilfulness has got it into its present unfortunate tangle. Upon the general character of Seward's diplomatic writings, the "Philadelphia Age" prints the following :—"2,102. Such is the ominous number of Mr. Seward's last despatch to Mr. Adams. These 2,100 despatches to one Minister cover the space of about six years, or 350 a year, or one—long ones, too—for every working day. If we suppose Great Britain to be one-fourth of Mr. Seward's diplomatic world, then we have 8,400 despatches in six years, or 4½ for every day. Surely no country ever had so prolific a Secretary. We remember to have heard an eminent man—once Secretary of State himself—say that he believed Seward had written more in quantity than all the previous Secretaries, 25 in number, from 1789 to 1861."

DURING the past year 6,334 vessels arrived in the Tyne from over sea, and 1,294 foreign vessels coastwise, against 5,587 from over sea, and 1,574 foreign vessels from coastwise in 1866; 1,377 vessels arrived with cargoes in 1867 from foreign, and 1,311 foreign vessels arrived with cargoes from foreign and coastwise. In all 2,688 vessels were cleared by the Custom House in 1867, against 2,566 in 1866. There were about 1,000 sail of either vessels less in 1867 than in 1866, showing the rapid progress that steam colliers are making in driving sailing vessels out of the coal trade. The increase in the number of vessels of large tonnage trading from the Tyne is very remarkable. In 1854 no vessels of 1,000 tons sailed from the Tyne. In 1864 43 above 1,000 tons sailed; in 1865, 72; in 1866, 58; and up to the 21st of December, 1867, 106. Nine of the number were of registered tonnage exceeding 1,500.

IMMEDIATELY on the completion of the "Hercules," which is expected to be ready for floating out of the dock in about a couple of months from the present time, it is intended to commence the construction of another new ironclad armour-plated ship of the "Hercules" class; the drawings and plans are now in course of preparation. The name by which the new ship will be designated has not yet been officially announced. In the designs for the new frigate care will be taken to adapt the new ship, by giving her increased tonnage and length, to the latest improvements in artillery by enabling her to mount guns of the heaviest description.

Miscellanea.

DURING the past year there have appeared 4,144 new books and new editions.

ENGLISH pheasants and hares were in the Montreal Christmas market, carried across the Atlantic in the icehouses of ocean steamers.

A TERRIBLE fire has destroyed the workings of the St. John del Rey Mines. Eighteen lives were lost. The fire is supposed to have been the work of an incendiary.

THE obituary of the "Times" of Wednesday records the death of seven ladies who attained the great ages of 95, 90, 86, 85, 84, 82, and 80 years; and of one gentleman aged 96.

THE present winter will form an epoch in the meteorological annals of Florence. Early in October the Apennines were thickly covered with snow, a rare occurrence at that season.

THE Warsaw official "Dziennik" publishes a ukase, in which the kingdom of Poland is no longer accorded the name it has held so long, but designated as the Vistula Province.

FROM lack of economy, in reduction of ores, it is estimated that the aggregate loss on the production of bullion in the United States for the past year will reach the sum of 25,000,000 dollars.

ACCORDING to a table prepared by Messrs. Pixley, Abell, and Langley, the export of silver from Southampton to India, China, and the Straits, which in the previous year amounted to £2,365,626, and for many years back has run up from £3,000,000 to £14,000,000, was in 1867 only £642,912.

AT the South Kensington Museum the visitors during the week ending January 4 were :—On Monday, Tuesday, Wednesday, and Saturday, free from 10 a.m. to 10 p.m., 11,010; on Thursday and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,060—total, 12,070. Average of corresponding week in former years, 8,084. Total from the opening of the Museum, 7,136,824.

CAPTAIN Shaw's annual report respecting the state of the fire brigade shows the number of fires in the course of the last year. In 1865 there were 1,500 fires, of which 1,205 were serious; in 1866 there were 1,300 fires, of which 326 were serious; and in 1867 there were 1,397, of which 245 were serious, the decrease in the number of serious fires showing the effectiveness of the fire brigade.

ON Tuesday evening next the 14th inst., at the Institution of Civil Engineers, Mr. Charles Hutton Gregory will deliver an inaugural address, on assuming the chair for the first time after his election as president. It is understood that Mr. Gregory proposes to refer principally to the assistance rendered by civil engineers in constructions for defence from hostile attack, and to improvements of weapons of war.

A HIGHLY interesting lecture, the main feature of which consisted in tracing to physiological phenomena the principles of the most approved and important mechanical and chemical inventions of modern times, was delivered at the Jews' College, Finsbury-square, a few evenings since by the principal, Dr. Friendlander. The learned lecturer explained how even familiar engineering contrivances were based on ordinary arrangements of natural origin. Various amusing illustrations were given in the course of the remarks.

A METEOR was observed about a week since in the neighbourhood of Havre, at about half-past seven in the morning. The nucleus of a crimson red colour, about the size of a star of the first magnitude, was followed by a luminous train which lasted some seconds, and which was succeeded by a white cloud, which continued for twenty-five minutes before it disappeared. The luminous body in its flight cast off a great number of sparks resembling small stars. Near Pont-Audemer (Eure), the meteor disappeared with a loud report.

MOST of the north country ploughing matches take place during the winter months. Among the most important meetings are the two which have just been held—one at Roxdale, on the last day of 1867, and the other at Brancepeth, on January 2. There was a large attendance at both meetings, and the contests for the All England champion prizes were watched with great interest. These were both won with Ransome's ploughs, and the work was considered extremely good.

IT is stated that the gold mines of Nova Scotia, taking their magnitude into account, are among the most productive in the world. The yield in 1866 was 25,464 ounces, and this year it is expected to reach thirty thousand ounces. The quartz-crushing has been especially successful, and the earnings of individual miners averaged upwards of three hundred pounds per annum. These facts will serve to make Nova Scotia a more attractive field of emigration than it has hitherto been.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1463, 1467, 1494, 1495, 1517
BUILDINGS AND BUILDING MATERIALS—1458
CHEMISTRY AND PHOTOGRAPHY—1465, 1472, 1478, 1487
CULTIVATION OF THE SOIL, including agricultural implements and machines—1452, 1497, 1499
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1455, 1457, 1466, 1468, 1477, 1488, 1501, 1502, 1507, 1510
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1485, 1492, 1493
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1519
GENERAL MACHINERY—1447, 1451, 1453, 1454, 1456, 1460, 1462, 1479, 1480, 1481, 1482, 1483, 1516, 1518
LIGHTING, HEATING, AND VENTILATING—1448
METALS, including apparatus for their manufacture—1461, 1498, 1515, 1520
MISCELLANEOUS—1450, 1459, 1464, 1470, 1474, 1475, 1490, 1491, 1504, 1506, 1508, 1509, 1512, 1513
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1471, 1476, 1500, 1505, 1511
SHIPS AND BOATS, including their fittings—1469, 1473, 1496, 1503
STEAM ENGINES—None
WARFARE—1449, 1484, 1489, 1514

1447 J. M. NAPIER. *Improvements in printing machinery.* Dated May 16, 1867.

The patentee claims the arranging intaglio printing machinery in such manner that printing plates may be carried round in a circuit with the faces of the plates uppermost, such plates passing under pressure apparatus, and being inked and wiped at suitable places in the circuit. The arranging intaglio printing machines so as to cross-ink the printing plate, or in such manner that the printing plate is inked by rollers traversing the plate both longitudinally and transversely. The employing in intaglio printing machines, wiping rollers, and other wiping surfaces having a leather surface based upon india-rubber. In intaglio printing the use of hard rollers or surfaces to receive the ink taken off the plates by wiping rollers or surfaces, and the use of doctors, scrapers, or rubbers to gather the ink from such hard rollers or surfaces, as set forth. The arranging intaglio printing machines in such manner that as the plate passes through the machine it may be wiped by an endless chain of wiping surfaces, in the manner set forth.—Patent completed.

1448 G. T. BOUSFIELD. *A new and useful method of manufacturing illuminating gases.* (A communication.) Dated May 16, 1867.

The patentee claims, first, the combination of the gas-making retort with a supply valve (for the introduction of the gas material), and with a slide (to move the said material forward in the retort), substantially as set forth. Second, the combination of the gas-making retort with a discharge tube terminating in a reservoir of liquid which prevents the entrance of air or the escape of gas, and per

Digitized by Google

mits the residuum of the gas material to be removed without opening the retort, substantially as set forth. Third, the progressive method or process of manufacturing gas substantially as set forth, consisting in moving the gas material forward at intervals in the retort. Fourth, the method or process substantially as set forth of decomposing the gas material in a heated retort in the presence of a current of electricity. Fifth, the combination of the gas-making retort with a battery in such manner that a current of electricity is caused to operate upon the gaseous matter evolved in the retort from the gas material, substantially as set forth.—Patent completed.

1449 J. H. JOHNSON. *Improvements in breech-loading fire-arms.* (A communication.) Dated May 16, 1867.

This invention is not described apart from the drawings. —Patent completed.

1450 G. F. HARRINGTON. *Improvements in the construction of marine baths.* Dated May 16, 1867.

This invention has reference to baths subject to the rise and fall of the tide, and consists in so constructing and arranging the baths that in lieu of the dressing rooms floating with the baths they are fixtures, being constructed upon piles fixed or driven into the bed of the sea, the baths being allowed to rise and fall with the tide, being guided and kept in position by or between the piles on which the dressing rooms are built.—Patent abandoned.

1451 C. E. BROOMAN. *Improvements in sewing machines.* (A communication.) Dated May 16, 1867.

This invention refers to sewing machines for producing what is known as the shuttle or double lock stitch. The improvements consist, first, in the employment of an upright oscillating or vibrating shuttle carrier when operated by an eccentric, or its equivalent, for the purposes explained. Second, in the employment of a spring clamp for holding the shuttle in place while in operation, for the purpose explained; and, third, in the general arrangement or combination of parts of shuttle machines, as described. —Patent completed.

1452 J. G. GRIFFITHS. *A new or improved combined apparatus for sowing seeds, hoeing, raking, and other horticultural purposes.* Dated May 16, 1867.

This invention relates to the construction of a new or combined apparatus or instrument for the purpose of sowing seeds, hoeing, raking, drilling, potting, cutting, and other gardening or horticultural purposes, and consists of a wooden handle and stock, at the end of which a hoe is fixed by means of a metal socket; the top of the hoe blade being formed of a triangular shape with two points serves as a crocking or potting iron; a female screw is cut in the centre of the hoe and potting iron, into which the stem of a rake and drill is screwed, the rake and drill being formed on curved arms diverging from each other at the end of the stem. The seed box is placed on the top of the stock on a bridge, and is secured by a pin passing through metallic flanges of the seed box, and through the stock, the pin being attached to a short length of chain from the handle. The seed box is provided with seed sifters perforated with different sizes of holes, according to the seed used, and the bottom of the box is likewise perforated with apertures for the seed to fall through; these apertures are closed by sliding plates, in such manner that the rows of seed may be regulated to the width required; a small hammer or pricker is fixed by a shoe and screws to the under part of the handle; and under the stock a Turkish saw blade is carried by inserting one end (which is a screw) in a cavity in the stock, and the point of the blade under a leather strap. The knife may take the place of the rake and drill by screwing it into the centre of the hoe and potting iron.—Patent abandoned.

1453 J. SADLER. *An improved nail-cutting machine.* Dated May 16, 1867.

This invention consists in the application of a shaft rotating at one half the speed the main shaft of the machine rotates at, which main shaft gives motion to the cutting blade by means of a crank and lever. Upon the slower rotating shaft the inventor places an eccentric, from which eccentric, by means of a band and rod, he communicates an oscillating motion to a lever fixed upon a vertical shaft, to this lever he connects a guide which moves the nail plate from side to side of the cutting blade, from which plate the blank for the nail is cut. From this lever he also carries a rod to another lever of somewhat similar construction to the last, communicating an oscillating motion to this second lever which carries the plate from which the nail blank is made. This second lever is constructed with means of regulating the angle at which the nail plate is required to be to the face of the cutting blade at the moment the nail blank is cut off, so that the blank may be of the proper size and shape requisite for the nail. And the nature of the invention further consists in the employment of two nippers operating each in combination with one pair of holding dies. He communicates motion to these by tappets upon the slower rotating shaft referred to above, or upon another shaft rotating at one-half the speed of the main shaft used for giving motion to the cutting blade. And the nature of the invention further consists in the combination of a shaft (rotating at half the speed the shaft referred to in this specification as the main shaft) with two tappets upon it, each acting upon separate levers; the oscillating motion thus given to the levers moves forward the heading bolts which head the nails.—Patent abandoned.

1454 J. M. STANLEY. *Improvements in producing and increasing combustion in blast and other furnaces, and also for generating steam and for other similar or analogous purposes.* Dated May 16, 1867.

The patentee claims the use and application of highly superheated or decomposed steam combined with heated air, so as to produce increased and more complete combustion for the several purposes, and by the various means described and illustrated in the drawings accompanying the specification.—Patent completed.

1455 J. DENIS. *Improvements in the treatment and preparation of fibrous substances or vegetable matters as pulp for the manufacture of paper, and in apparatus for the same.* Dated May 17, 1867.

We cannot here give space to the details of this invention.—Patent completed.

1456 F. P. WARREN. *Improvements in tobacco pipes.* Dated May 17, 1867.

The patentee claims the construction and arrangement of tobacco pipes in such manner as that the smoke after passing down through the interior of the bowl or chamber containing the tobacco is caused to come in contact with the outer surface of such bowl or chamber, or to pass through or along a suitable passage or channel, or passages or channels (continued to the top of the bowl and closed by a plug or plugs), in such manner as to be acted upon and dried or deprived of its essential oil and other moisture by the heat emanating from the bowl or chamber in which the tobacco is being burnt.—Patent completed.

1457 H. PEEL. *Improvements in looms for weaving lastings and serge-de-berries, applicable also for weaving other fabrics.* Dated May 17, 1867.

This invention relates to means or apparatus for working or operating the heulds or heddles in the looms above named, and consists in the employment of treading tappets having side grooves and treading levers with friction pulleys to run in the grooves. These levers are connected to ordinary jack-reds to which the top parts of the heulds or heddles are attached by usual connecting rods, and are also connected with the bottom part of the heulds or heddles by other levers, by which means both up and down motion is given to the heulds, thus dispensing with the weights or springs now used —Patent completed.

1458 P. M. PARSONS. *Improvements in the manufacture of artificial granite and other artificial bricks and blocks suitable for buildings, engineering, structures, pavements, and other similar purposes.* (A communication.) Dated May 17, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

1459 A. ANGOT. *An improved spring petticoat termed "The Empress."* Dated May 17, 1867.

This invention is not described apart from the drawings. —Patent completed.

1460 H. HOLLINGSWORTH. *An improved shoe for piles* Dated May 17, 1867.

The objects of this invention are, first, to get a more certain foundation where piles are used for that purpose. Second, a great saving of time, labour, and power in driving. These objects are attained in the following manner, that is to say:—The shoe is made longer than the ordinary shoe, and upon the upper part thereof is a projection or swelling larger than the body of the pile, which projection or swelling clears the way for the pile as it is driven, thereby greatly reducing the friction on the sides of the same, and allowing it to be driven home with greater ease than hitherto, and more certainty of its resting on a solid foundation. The shape and size of the swelling or projection depends to a great extent upon the nature of the ground it may be used upon. It is estimated that the use of piles with these shoes will effect a saving of more than 50 per cent. in time, power, and labour required to drive the ordinary pile. The foot of the pile is fitted into the shoe and secured with one or more bolts or pins passing through the pile and riveted to the shoe.—Patent abandoned.

1461 A. L. DOWIE. *Improvements in treating iron to obtain metallic compounds for various uses.* Dated May 17, 1867.

Iron treated according to the first part of these processes, that is to say, with marine shells, or their equivalent, or according to that and other parts of the processes, but without having other metals alloyed therewith, forms what may be termed varieties of improved cast iron (that is, a compound consisting, principally, of iron and carbon, or of iron and a substance or substances replacing the carbon) which may be used like ordinary cast iron or otherwise. The details of the invention are too voluminous to be produced here.—Patent completed.

1462 J. SMITH. *Improvements in driving sewing machines and in apparatus employed therefor.* Dated May 17, 1867.

This invention consists in the application of the motive power of clockwork to drive the ordinary sewing machine, and in the arrangements for carrying the same into effect. To drive the ordinary sewing machine the inventor applies thereto, in any suitable position, according to the construction of the machine, an arrangement of clockwork consisting of a frame containing an ordinary barrel furnished with a proper clock spring, with arbor, cog-wheel, ratchet, and click complete. This barrel is also furnished with a maintaining spring. The cog-wheel of the barrel drives a pinion, the arbor of which is furnished with a large driving wheel, over which passes an endless band or belt communicating motion to the driving shaft of the sewing machine by means o a pulley fitted thereon. In lieu of a band or belt suitable gearing may be employed. On the arbor of the above-said pinion he fixes a bevil wheel which moves an endless screw furnished with a fan or fly, by which a regular motion is obtained, and which also serves for stopping the machine. The clockwork is wound up for action by means of a key applied on the barrel arbor, or by means of an arrangement of levers. Instead of one barrel two may be employed.—Patent abandoned.

1463 W. R. LAKE. *Improvements in water gauges for steam boilers.* (A communication.) Dated May 17, 1867.

This invention consists, chiefly, in constructing a water gauge with one or more sides or faces formed of transparent mica, which is secured in a metal frame or case provided with suitable means for attachment to a steam boiler.—Patent completed.

1464 W. R. LAKE. *Improvements in the manufacture of white lead.* (A communication.) Dated May 17, 1867.

Sulphate of lead and carbonate of baryta, in the proportion of 100 parts by weight of carbonate of baryta to every 152 parts of sulphate of lead, are placed in a vessel, to which is added water, the mixture being stirred until it is all reduced to a thin paste. After it has been well combined by thorough stirring, the said mixture is heated for three or four hours to a temperature of about 160 deg. Fah., though this temperature may be considerably reduced, or may be raised to nearly the boiling point without materially affecting the result. The stirring is continued during this part of the process. This treatment will cause the following interchange of elements to take place, namely, the sulphuric acid of the sulphate of lead combined with the baryta forming sulphate of baryta, and thus liberating carbonic acid, which unites with the lead, forming carbonate of lead. This is then dried in the ordinary way.—Patent completed,

1465 W. R. LAKE. *An improved mode of producing chloride or oxy-chloride of lead, and treating the same for manufacturing white lead.* (A communication.) Dated May 17, 1867.

This invention consists, first, in the treatment of oxide of lead with the chloride of sodium, or its equivalent, substantially as described, for producing a superior chloride or oxy-chloride of lead. Second, in the production of a chloro-sulphate or white lead from a chloride or oxy-chloride of lead for the purpose, substantially as described. Third, in the production of a carbonate of lead from a chloride or oxy-chloride of lead for the purpose, substantially as described.—Patent completed.

1466 G. BERNHARDT. *Improvements in or applicable to throstle and doubling frames and machines of like character for spinning, twisting, and doubling fibrous materials.* Dated May 17, 1867.

This invention consists, first, in the use in that description of machines mentioned in the title of bobbins with bevilled ends, instead of the square-ended bobbins hitherto used, by which there is less breakage of yarn in unwinding the thread, and the "ends" are more readily found when broken. Second, the invention relates to a modification of the ordinary traverse or copping motion for distributing the thread upon the bobbins, so that the extent of traverse will gradually increase as the bobbins fill with thread to suit the taper or bevilled ends of the bobbins used according to the first part of this invention. —Patent completed.

1467 S. REGAN. *Improvements in marine and land boilers and their furnaces, and also other furnaces used for the manufacture of iron and other purposes.* Dated May 17, 1867.

One part of this invention has reference to an improved arrangement of steam boilers, whether for marine or land purposes, and consists of three vertical cylinders placed concentrically, at suitable distances apart, dependent upon the size of the boiler required. The inner cylinder (which forms part of the water space) is egg-ended, its lower extremity being connected to a "blow-off" pipe which passes through the fire-grate into the ashpit. This inner cylinder is connected by means of tubes placed at suitable intervals around its circumference, and in an angular position with the middle or intermediate cylinder, and is thus connected with the water space between such intermediate and outer cylinder. The lower part of the intermediate cylinder bulges outwards, and thus forms the area for the fire-grates, which are placed within the bottom. The patentee also connects the upper portion of the inner cylinder above the water level by means of tubes with the intermediate cylinder for the escape of steam, which may be discharged into the main or outer steam chamber. The upper ends of both the intermediate and outer cylinders are of egg-end formation, having a chimney passing through them which communicates with the space between the inner and intermediate cylinders. The heat from the fire passes up this space into the chimney, enveloping the tubes on its passage, as well as acting upon the surfaces of the intermediate and inner cylinders, thus rapidly generating steam, the tubes (which are of conical or parallel formation, the ends being flanged for riveting, or they may be caulked or drifted in the usual manner) acting as an efficient stay between the two cylinders. The chimney he builds up from the top of the intermediate cylinder, and passes it through the outer one, securing the same by angle iron in the usual way. Upon the top of the outer cylinder he also places a dome or steam chamber which surrounds the chimney. From the bottom of the inner cylinder depends a blow-off pipe passing through the centre of the furnace. Two or more pipes opposite to each other, and connected to the water space of the bottom of the boiler, also communicate with the blow-off pipe, aiding it in such operation; and when the blow-off cock is turned off, they aid each other in causing free circulation. Ordinary boiler fittings are of course used. The fire-bars may be rotary, and fed from a hopper, or they may be stationary.—Patent completed.

1468 E. WEBB. *Improvements in looms for weaving hair cloth and other analogous fabrics.* Dated May 17, 1867.

This invention is not described apart from the drawings. —Patent completed.

1469 A. V. NEWTON. *Improved apparatus for lowering detaching, and picking up ships' boats.* (A communication.) Dated May 17, 1867.

For the purpose of overcoming the dangers incident to the raising, lowering, and casting off of ships' boats, and to render the access to and from a boat safe, the first part of this invention consists in so constructing the davits, and so applying them to a vessel or ship, that they shall have a swinging motion towards and from the water, and at the same time admit of being turned around like cranes when they are in an upright position, so that a boat can be swung inward over the vessel. The second part of the invention consists in providing for raising and lowering a boat, and swinging the davits by means of ropes applied to drums upon a shaft, which is provided with a friction brake and hand wheel, and otherwise constructed and arranged in such manner that a single person can conveniently and safely effect the swinging of the davits, and the lowering and raising of a boat. The third part of the invention consists in combining springs or weights with vertically swinging davits in such manner that the tendency of the latter shall always be to assume an upright position when unrestrained by the weight of the boat, so that when a boat which is launched, but moored to the davits, rises upon a wave, the davits shall also rise, and thus prevent collision and injury to passengers in the boat. The fourth part of the invention consists in providing for a safe communication for persons between a boat which has been lowered into the water and the vessel by the application of ladders and hand rails to the vertically swinging davits. The fifth part of the invention relates to the employment of certain mechanical devices in conjunction with vertically swinging boats-davits for allowing of the raising and lowering of a boat upon an even or level keel, for preventing fouling of the ropes, for facilitating the attachment of a boat to and its detachment from the davits, or hoisting and lowering ropes, and also for preventing severe and injurious jars and concussions of the apparatus in manipulating it in a storm, or during very rough seas.—Patent completed.

1470 C. E. FROEMAN. *Improvements in reckoning, counting, or calculating apparatus.* (A communication.) Dated May 17, 1867.

This invention cannot be described apart from the drawings.—Patent abandoned.

1471 J. L. CLARK. *Improvements in apparatus for communicating between the passengers, guards, and engine drivers of a railway train.* Dated May 17, 1867.

This invention consists in the application of a pneumatic tube running the whole length of the train, with suitable means for making connection between the carriages and break vans when coupled together, so as to form a train. A pump or bellows is fixed on the engine, and upon or beneath every guard's van, which is kept in constant action by the motion of the train, and continually exhausts the air from this pipe, all the bellows acting on the pipes simultaneously under ordinary circumstances; the pipe being closed, no air can be ejected by the bellows, and no effect will be produced in the guard's van, or engine; but if an opening be intentionally made into any part of the pipe by the passengers or guards, or by the accidental

Digitized by Google

separation of the train into two parts, the air will be freely admitted into the pipe, and all the bellows will come into action, and will begin to eject air violently. Thus, air is ejected through a powerful whistle, or other sounding apparatus, and by the noise it occasions, it immediately attracts the attention of all the guards in the train, and also that of the engine driver. Flexible tubes of vulcanized india-rubber, with spigot and faucet joints, are employed for making the connections between the carriages.—Patent completed.

1472 T. RICHARDSON. *Improvements in the extraction of oils from vegetable substances.* Dated May 18, 1867.

This invention relates to the extraction or separation of oils contained in vegetable substances, such for example as cotton seed, linseed, rape seed, and the cakes made from these or other oil-producing seeds, and consists in impregnating or mixing such seeds, either in their natural state, or when crushed, with a solvent of such oils as may be therein contained, and which solvent shall have a lower boiling point, and be more volatile than the oil to be extracted.—Patent abandoned.

1473 J. SLOAN. *Improvements in the construction of ships' water-closets.* Dated May 18, 1867.

The object of this invention is to provide a ship's water-closet of simple construction, which shall not be liable to get out of working order, shall allow the soil to flow freely away, and shall entirely prevent that back passage and splashing of water which takes place in closets as at present arranged, and is the cause of much discomfort, especially in ships of "light draught" of water. For these purposes the inventor employs the part hereinafter mentioned arranged as follows:—He takes an ordinary pan, and leads the soil pipe connected thereto in a curved or bent manner into a vessel of cylindrical or other shape placed alongside the pan. To the bottom of the said vessel which opens to the sea he fits a flap, or hinged, or other valve. The said valve is connected by a rod and links, or a chain to a weighted lever, coupled to a hand-pull or lift, placed adjacent to the seat. The weighted lever holds the valve up to its seating. To flush the closet the weighted lever is raised or moved by force applied to the hand-pull or lift, and when this is done, the weight of the soil on the valve causes it to open outwards. Should the ship roll or pitch at this time, or should she be struck by a sea, the valve being free, will close against its seating, and prevent back passage and splashing.—Patent abandoned.

1474 J. T. BLAND and E. J. BLAND. *More effectually regulating the supply of water or other fluids to cisterns or other receptacles, and for economizing the trouble and expense connected therewith by means of an apparatus to be called "Bland's improved ball-cock.* Dated May 18, 1867.

This invention cannot be described apart from the drawings.—Patent completed.

1475 C. P. BUTTON. *Improvements in hernia trusses, abdominal supporters, and surgical bands.* (A communication.) Dated May 18, 1867.

This invention has for its object improvements in hernia trusses, abdominal supporters, and surgical bands, by which an upward and inward pressure may be given to the pad, and the tension of the body spring, and the position of the pressure pad, may be regulated and adjusted at pleasure. These improvements consist, first, in the combination of a shoulder and adjustable bearing with a jointed body spring. Second, a rotating slide or arm to which the pressure pad is attached, fitted to a tubular socket, and secured in its place when adjusted by a set screw. Third, in the construction of a separate pad spring, and its combination with the pressure pad and body spring. Fourth, a cut or slit at the end of the rotating arm or slide, in which the end of the pad spring is placed, and may be turned, and is secured or clamped when adjusted by a set screw.—Patent abandoned.

1476 B. SHEIL. *Improved paving for roads and ways.* Dated May 18, 1867.

This invention consists in cementing together small stones into slabs, iron or wooden frames or moulds being employed for the purpose.—Patent abandoned.

1477 A. H. BRANDON. *Improvements in machinery for washing wool, the said improvements being also applicable to other purposes.* (A communication.) Dated May 18, 1867.

This invention relates to the endless apron or feeding mechanism which the patentee constructs of a series of horizontal and parallel rollers, revolving in the same direction in such a manner that the wool or other material charged upon the same is conducted towards the compressing rollers, the speed of these feeding rollers being alike as regards their revolutions in a given time, but, in order that the wool or other material should not accumulate unduly at different parts, he gives to them a gradually increasing circumferential speed by making each successive roller of a larger diameter as they approach the compressing cylinders.—Patent completed.

1478 H. A. DUFRENE. *An apparatus for transferring heat from one current of gas to another.* (A communication.) Dated May 18, 1867.

The objects of this invention are to collect the caloric contained in a current of hot gases for the purpose of heating a current of cold gases (and, in practice also, for heating cold gases or cooling hot gases), and to obtain this double action in a continuous manner; and the invention consists in the construction of apparatus by which these objects may be effected. This object may be obtained by means of a receiver containing metallic gauze or plates forming large absorbent and repelling surfaces, and through each part of which the two currents successively pass in opposite directions. When the hot current passes through, the metal surfaces are heated by contact with the gases, which are thereby gradually cooled, and which at their outlet are relatively cold. The cold current acting inversely will cool such metal surfaces, the caloric of which will heat the cold gases, which at their egress will be relatively hot, so that the caloric abstracted from the hot will be transferred to the cold gases. The apparatus may be constructed in various ways.—Patent abandoned.

1479 C. W. DIXON. *Improvements in slide-valves.* Dated May 18, 1867.

Consists of a rotating slide valve. The exhaust port may or may not be cast in one piece with the cylinder, as is usual in ordinary engines. The exhaust port is brought to the surface of a circular plane or convex face along with the steam ports, but is placed in the centre, and made of a circular form. The two steam ports are placed on opposite sides of it, leaving space for a rib of metal between them. The two steam ports are made of the following shape, but their size is to be regulated by the ordinary rules for finding the areas of steam and exhaust ports, and also having their outer and inner sides arcs of two concentric circles, and their ends parts of radius lines from the same centre. The valve is to have a circular face of the same size, and to cover the face on which the steam and exhaust ports are placed, and is to have two openings in it bounded by the same arcs as the steam ports are, but the other dimensions are to be regulated by the engineer, so as to give whatever cut-off of steam or exhaust he thinks proper. One of these two orifices opens direct into the steam chest through the back of the valve, but the other opening is connected by a covered passage on the back of the valve with the exhaust port in the centre, so that when the steam is entering at one port, it is exhausting at the other. The back of the valve is made cylindrical, and brought through a stuffing box at the back of the steam chest, and made of the same diameter as the exhaust port: or if liked smaller, or if expansion is used in the cylinder, it would be an advantage to be made larger. The valve may be worked by eccentrics from the crank shaft, or direct from the piston rod by a small connecting rod turned backwards, or in any other way at the option of the engineer.—Patent abandoned.

1480 J. SMITH and J. L. IRBOTSON. *Improvements in raising and lowering revolving shutters.* Dated May 18, 1867.

This invention consists in the use of a crank handle, whereby motion is given to toothed wheels, causing a drum or pulley to revolve. Round the said drum or pulley, and over a similar one at the top of the window, is drawn tightly a steel belt or band. The top pulley or drum is attached to a roller on which the shutter is coiled when wound up. A pawl works in the teeth of the toothed wheels, by which means the shutter can be stopped at any point. The said pawl is fitted with a handle, by pulling which the toothed wheels are released, and the weight of the shutters causes them to descend. To ease the dead drag on the rollers, and to cause the shutters to coil up more smoothly, a small friction roller is so fitted behind the shutter that it will pass over it on to the main roller. Instead of a friction roller, two loose pulleys may be employed, one at each end, which will serve the same purpose.—Patent abandoned.

1481 J. WHITE. *An improved binder for sewing machines.* Dated May 18, 1867.

This improved binder (which can be used for all kinds of sewing machines) consists of a curved plate of brass or other metal, having its edges turned over, and is tapered to a narrow part which curves near to the needle. The binding slips through between the slit formed by the curved edges, and the cloth or fabric passes between the curved parts. It rests flat on the plate of the sewing machine, and has an extended portion furnished with a slot, whereby it may be clamped by means of a screw or other means in any required position on the plate of the machine.—Patent abandoned.

1482 E. O. HALLETT and W. T. HALLETT. *An improved book-rest.* Dated May 18, 1867.

This book-rest consists of a small piece of wood or metal so curved or shaped as to fit across the knee comfortably. To this is attached a small tubular pedestal, which contains a spiral spring at its lower end, and receives a rod capable of being raised or lowered upon the spring. The top of the rod carries a small shelf, on which a book or paper can rest. The height of the shelf is regulated by raising or lowering the rod in the tube, and securing it by a set screw, while the spiral spring compensates for the oscillation when used in a railway carriage, or under other circumstances. The whole article is composed of several pieces, so as to render it portable, which may be screwed together when required.—Patent abandoned.

1483 G. HAYNES. *An improved apparatus for cleaning or brushing boots and shoes.* Dated May 18, 1867.

This apparatus consists of a frame of wood carrying a small crank shaft worked by a treadle, and communicating by cords and pulleys a revolving motion to a spindle on which are placed circular brushes, secured in blocks so that they may be removed if required, and also permit the operator to apply any part of a boot or shoe to the brush. Three brushes, forming a set, or more if required, may be placed on the same spindle at a small distance apart, so that the whole operation may be completed without removing the brushes, or causing any inconvenience.—Patent abandoned.

1484 W. E. GEDGE. *A novel system of cartridge for le fauchoux and other guns.* (A communication.) Dated May 18, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

1485 J. L. NORTON. *Improvements in drying malt, and also tanners and distillers' grains and spent hops.* Dated May 18, 1867.

In performing this invention, the patentee passes the materials into a casing, by preference of a cylindrical form, and placed horizontally; a current of heated air is caused, usually by means of a fan or steam jet, to pass through the casing from end to end, and the casing is caused to revolve. The material is fed in at one end of the casing, and is discharged at the other, the material traversing the casing in the opposite direction to the current of heated air. The continuous motion of the material through the casing is produced by a number of shelves in the interior of the casing, which, as the casing revolves, raise the material from the bottom of the casing, and, when it gets nearly to the top, allows it to fall back, and, in falling, it comes against inclined directing plates mounted on an axis passing through the casing. The inclination of the directing plates is made adjustable to allow of the due regulation of the time during which the material is subjected to the drying operation.—Patent completed.

1486 J. L. NORTON. *Improvement in machinery for washing and drying wool and other materials.* Dated May 18, 1867.

The first part of these improvements relates to machines in which the wool is agitated and moved forward in the washing liquid by revolving inclined blades or screw propellers. Instead of making the blades of these propellers all inclined in one and the same direction, and making them all revolve in one direction, the patentee makes them as follows:—He uses a number of separate propellers placed on one common axis, and he makes the blade of every alternate propeller inclined in the reverse direction to the others, so that the blade of the first, third, and fifth propellers will be set in one direction, and the blades of the second, fourth, and sixth in the other direction, and all those the blades of which are inclined in one direction are made to revolve in such direction as to cause a tendency of a forward motion of the water in the trough. The other propellers are caused to revolve in the reverse direction to these, but as they also have their blades inclined in the reverse direction, they also cause a tendency to a forward movement in the water. The propellers may be revolved in various manners. The next part of the invention also relates to the agitating and moving forward of the material in the washing trough, and consists in arranging a number of forks or rakes to work in the trough, and suitably connecting these forks with mechanism so arranged that they shall have a swinging or rocking motion, and at the same time be moved forward in the trough until they shall have arrived at the end of the forward stroke, when they are lifted up partially or entirely out of the water during the return stroke, and as they arrive at the end of the backward stroke, they are again let down into the water, and the swinging action imparted to them as they again move forward. For lifting the wool out of the water after it has been washed, the patentee uses a fork, to which motion is imparted by a crank to which the fork is jointed; the fork is also connected to levers or instruments which govern its inclination, so that the fork shall be gradually inclined more and more towards a horizontal line as it moves forward, and, in going back, it is lifted by the crank out of the water. The invention comprises various other arrangements which we cannot produce here.—Patent completed.

1487 T. METCALF. *Improvements in burning all hydro-carbon oils, such as creosote, petroleum, paraffin oil, shale oil, gas tar, and other similar products capable of being used as fuel.* Dated May 20, 1867.

This invention consists in improved arrangements and apparatus for converting hydrocarbon oils and similar matters into gas before they are consumed, which arrangements and apparatus are applicable to stationary, marine, and locomotive boilers, retorts, stills, warming pans, and all purposes where heat is required. The patentee constructs a gas box of metal, or other material, of any suitable length, and transverse shape or section, according to the demand for heat, or the purpose to which the heat is to be applied. To the top of the gas box, near its front end, he attaches a feed pipe communicating with the reservoir containing the hydrocarbon, the pipe being provided with a tap for regulating the supply, or shutting the supply off. He also attaches to the top of the gas box a safety pipe with a tap or valve for preventing the danger of explosion, and at the opposite or back end of the box he drills small holes. The gas box is fitted into the front of the flue of the boiler, or other vessels, and the front end of the gas box is heated by ignited fuel in a small stove or grate, and when the tap of the feed pipe is opened, the hydrocarbon, after entering the gas box, is immediately converted into a large volume of gas, which rushes through the small holes into the flue, and then being ignited, gives out an immense body of flame with an intense heat, their being neither smoke nor smell when the supply is properly regulated. He prefers to employ a separate cover at the front of the gas box fixed by bolts or screws, and to have in the cover as many stuffing boxes as there are small holes at the back of the gas box, for holding rods in the pointed ends for cleaning the small holes, and closing them when required. There are modifications included.—Patent completed.

1488 J. BOTTOMLEY. *Improvements in looms for weaving.* Dated May 20, 1867.

The patentee claims, firstly, the use of horizontal weft forks or prongs in conjunction with revolving grates, in either single or double box looms, essentially in the manner shown and described. Secondly, the mode of keeping separate the various threads in box looms by having tables or traps open temporarily between the boxes and the shuttle board, whilst the boxes are being revolved or turned, as shown and described.—Patent completed.

1489 T. MCCOMAS. *Improvements in raising sunken vessels.* (A communication.) Dated May 20, 1867.

This invention has reference to facilitating the raising of sunken ships and vessels in deep or shallow waters by employing for the above purpose the generation and expansion of hydrogen or aeriform gases within any suitable apparatus, by the agency of which the said ships or vessels are raised.—Patent completed.

1490 H. A. DUFRENE. *Improvements in beer and other like engines.* (A communication.) Dated May 20, 1867.

This apparatus consists of three receivers, one for containing air compressed by any suitable means, the two others being wood or metal cylinders containing the beer or other liquid, one emptying while the other fills; each of these cylinders has a piston without a rod floating on the surface of the beer. Two pipes furnished with taps are adapted to the bottoms of the cylinders, and extend to the part at which the beer is to be delivered. The tops of the cylinders are put in communication with the receiver of compressed air by two other pipes also provided with taps. Thus, when a cylinder is full of beer, communication is opened between the receiver of compressed air, and the delivery pipe, the air being compressed causes the beer to rise in the delivery pipe, and the piston lowering with the liquid, keeps it from contact with the air. The apparatus being empty, fills alone. A barrel full of beer is placed at the top of the apparatus, the two communications above named are closed, and the barrel and the lower part of the cylinder put in communication; the beer then passes into the cylinders and raises the piston. The air escapes through a valve placed at the upper part, and which the piston closes, when, the cylinder being full, it comes near to the cover. The valve in closing prevents the air from escaping, and the flow ceases of itself.—Patent completed.

1491 A. M. CLARK. *An improved instrument for sharpening cutlery.* (A communication.) Dated May 20, 1867.

This invention is not described apart from the drawings.—Patent completed.

1492 C. D. ABEL. *A new or improved machine or apparatus for filling sacks with grain, flour, bran, sugar, and other granular or pulverous substances.* (A communication.) Dated May 20, 1867.

This invention has for its object to fill sacks easily and quickly with grain, flour, and other granular or pulverized substances, and more particularly bran, by the aid of one attendant only. For this purpose a hopper for containing the grain, or other substances, is mounted upon a framing, over the mouth of which hopper is fixed the sack to be filled, it being held firmly in that position by means of a strap. Inside the mouth of the hopper is a piston or ram, the upper end of which is connected by means of a rod to a lever, the fulcrum of which is carried by an arm fixed to the framing, while the free end thereof is provided with a handle, whereby the attendant imparts to it, and consequently, also to the piston or ram an up and down motion. To facilitate such motion the lever has a tail piece provided with a balance weight, and the free

Digitized by Google

end thereof works between guides fixed to the framing. The piston or ram, the diameter of which is somewhat less than that of the sack, is caused by its weight and the reciprocating motion imparted to it to press the grain or other substance firmly into the sack.—Patent abandoned

1493 E. H. C. MONCKTON. *Improvements in preserving meat, fruit, and vegetables.* Dated May 20, 1867.

This invention consists in placing the articles to be preserved in cases hermetically sealed, into which either is poured, the orifice on the expulsion of the air by its vapour being immediately sealed up.—Patent abandoned.

1494 H. CHAMBERLAIN. *Improvements in steam boiler and other furnaces.* Dated May 20, 1867.

This invention relates to an improved mode of applying and economizing the heat of steam boiler and other furnaces, and consists in storing a large proportion of the heat which has hitherto been lost or wasted by being carried by the draught up the chimney before it has had time to become absorbed by the boiler-plates or other surface to be heated. According to this invention, as applied to marine and Cornish boilers, for example, the patentee proposes to pack or fill in the flue behind the furnace or fire-bridge with open brick-work of fire brick, fire tiles, or fire clay lumps, made either solid or hollow, the interstices being so displaced as to sift the current of hot air without stopping the draught. By this means the heat which is not immediately taken up by the boiler plates is stored in, or collected by the fire bricks, whence it radiates off to the boiler. These fire bricks soon attain a very elevated temperature throughout the entire portion or length of the flue on which they are placed, and impart a more uniform degree of heat throughout the length of such flue. An additional supply of air may, with this arrangement, be admitted to the fuel above the grate, and hence a more perfect combustion is obtained, and the prevention of smoke effected, with a corresponding economy of fuel.—Patent completed.

1495 J. G. TONGUE. *Improvements in the arrangement and construction of furnaces for steam boilers and various other useful purposes.* (A communication.) Dated May 20, 1867.

This invention is not described apart from the drawings. —Patent completed.

1496 E. BOND. *Improvements in the building or construction of ships' sail yards.* Dated May 20, 1867.

In performing this invention the inventor takes one or more flat longitudinal plates of steel of any given depth, and suspends the breadth thereof in a vertical position in order to take the strain of the sail and leech ropes thereof; to this longitudinal plate or plates erected in its edge, he secures in a suitable manner four or other suitable number of angular troughs or other sectional shaped plates of steel in a horizontal position, in order to take the strain of the yard braces and "clues" of the upper sail, and to give greater support to the vertical plates. By way of rendering the structure more firm and rigid, he bolts iron braces thereto, in order to secure the one horizontal plate or plates to another vertical plate or plates. To the horizontal plate of steel which stands out before the yard, he secures the jack stay of the yard by strong iron bolts, and the yard is suspended to the mast much in the ordinary manner of sail yards. By these means he secures facilities in sail furling, as instead of the sail being furled upon the yard, it is laid upon and made fast to the sides or centre thereof, thus being more secure from the force of the wind, and requiring a smaller amount of canvas when set.—Patent abandoned.

1497 V. BARFORD. *Improvements in boilers for boiling or steaming roots, and for heating water for other purposes.* Dated May 20, 1867.

The boiler for containing the water to be heated the patentees make of an upright cylinder closed at the bottom, and supported on suitable legs or wheels. The top of the cylinder is either closed over with a movable lid, or a "steamer" with a perforated bottom may be placed above it, when it is desired to employ the boiler for steaming roots. Projecting out from one side of the upright cylinder, and forming one vessel with it, is a cylinder or tube of other form, which is of smaller diameter than the first-named cylinder which is to contain the greater portion of the water to be heated. Passing up vertically through the centre of the smaller tube is again a still smaller tube forming a fire-box, so that an annular space is left around this tubular fire-box, and into this annular space water flows from the interior of the larger cylinder, so that the tube forming the fire-box is surrounded with water.—Patent completed.

1498 E. YOUNG. *Improvements in treating iron ores to remove phosphorus therefrom.* Dated May 20, 1867.

For this purpose the patentee roasts the iron ore in a gas furnace, by preference that known as Siemens' regenerative gas furnace. He employs in the gas producer or producers a fuel rich in sulphur, or he mixes sulphur, or substances containing sulphur with the fuel. The gas from the producer or producers is led into a chamber or furnace containing the wet, damp, or moist ore to be treated, and is there burnt in contact with the ore, by the admission of a quantity of ore insufficient to produce complete combustion, so that the ore may be submitted to the action of bisulphide of carbon, or other sulphur compounds. Under these circumstances, sulphur is found to replace the phosphorus in the ore. In order afterwards to separate the sulphur from the ore, the ore is submitted to a further roasting process in the presence of an excess of air, either in the same or other furnace or chamber. —Patent completed.

1499 W. M. CRANSTON. *Improvements in reaping and mowing machines.* (A communication.) Dated May 20, 1867.

This invention has for its object to improve the cutting apparatus of reaping and mowing machines, to enable them to cut closer to the ground, and also to cut the crop below the horizontal bar which carries the fingers and knife of the cutting apparatus, in order that at the top of the uncut stubble shall not come in contact with the underside of the bar, or not to such an extent as heretofore, and thus friction is avoided. For this purpose the fingers are bolted at intervals to the underside of the horizontal bar, whilst on the upper side of this bar is carried the bar to which the knives are attached, as is usual; but in place of the knives being parallel with the finger bar, as heretofore, the patentee causes them to incline downwards at an angle, so that their points shall become below and cut the crop on the underside of this bar; the slots in the points of the fingers, through which the knife works, are similarly shaped downwards.—Patent completed.

1500 D. THOMSON. *Improvements in steam rollers for rolling roads, and in pitch chains for working the same, and for other purposes.* Dated May 20, 1867.

In constructing rollers for rolling roads to be propelled by steam power, the patentee forms the roller in two halves lengthwise, the two halves being on the same axle, but driven separately by the steam power, in such a way that either half can be detached and move loosely on that axle, while the other is driven by the engine, and thus the turning of the machine on the road is made easier. He steers, turns, or guides the machine by two wheels, which work in separate frames, turning on perpendicular axes, but which are so connected by levers or screw wheels that the two wheels always revolve in parallel planes, and the steerage of the machine is effected by causing the said frames to turn to any required degree on their perpendicular axes. He forms the framing of wad rollers propelled by steam power of a box formed of wrought-iron plates and angle irons, completely enclosing the roller except on the underside, where it rests on the ground, so as to attain the greatest stiffness and rigidity in the framing, and the box is prolonged at each side to embrace the boiler, steam machinery, and the steering apparatus in the same rigid framework. He forms the rollers of wrought-iron plates and angle irons riveted together so as to make a complete and rigid roller, and he then adds plates of iron to the external circumference, and secures them by bolts, so as to be easily renewable when worn by contact with the road. In making the pitch chains that have been generally used for working road rollers and traction engines, he forms the said chains of cast iron, malleable cast iron, or other cast metal, by having each alternate link cast with an opening in the side to admit the next link which is cast whole or close all round, and he closes the said opening by a piece of metal inserted therein, and secured by one or more bolts or rivets. Pitch chains made in this way are equally applicable to chain pumps, grain hoists, or other machines which are worked with pitch chains passing over toothed wheels.—Patent completed.

1501 J. OWENS. *Improvements in the manufacture of pile and other fabrics.* Dated May 21, 1867.

This invention is applicable to those pile fabrics in which the pile is produced by floating the weft threads over the warp threads, and then cutting the weft threads, and it consists in an improved mode of weaving by which the whole of the pile weft appears on the face, and the back is a plain fabric.—Patent abandoned.

1502 J. DAVIES. *Improvements in machinery for folding sheets of paper or other fabric or material.* Dated May 21, 1867.

This invention is not described apart from the drawings. —Patent completed.

1503 E. H. C. MONCKTON. *Improvements in the construction of a steam vessel suitable for ferrying laden trains across the ocean complete, together with its landing places, breakwaters, and modes of protection from marine insects and fouling, which improvements are also generally applicable to other vessels, and to the protection of iron and wood exposed to the action of the sea water.* Dated May 21, 1867.

The specification of this invention is too voluminous (it consists of forty pages) to be quoted here at sufficient length for an intelligible abstract.—Patent abandoned.

1504 J. GOUGH. *Improvements in arming presses for producing devices on the covers of books and other articles.* Dated May 21, 1867.

This invention consists, first, in improvements in the gauges employed for the correct adjustment of the book cover or other article to be impressed underneath the die plate. To these gauges the patentee attaches springs, which rise above the level of their upper surface, and serve to prevent the edge of the book cover or other article from being pushed over the gauge, but which are flattened down on the gauge by the die plate when the impression is being given. The second improvement relates to the mechanism employed to force down the die plate on the substance to be impressed, the table which supports the said substance being a fixture above the heater box (to the underside of which the die plate is attached), and underneath the head frame of the machine a shaft is mounted in suitable bearings free to revolve therein; to this shaft a continuous rotary motion is imparted by suitable gearing. He forms an eccentric on this shaft, and supports the shaft immediately on each side of it by extra bearings formed in the head frame of the machine. This eccentric is made to bear against the circumference of a friction roller mounted in suitable bearings on the upper side of the said heater box; as the shaft revolves, the eccentric depresses the box together with the die plate. Balance weights are employed to raise the box again. When it is thought desirable to give two impressions for one revolution of the said shaft, he substitutes a double-acting cam for the eccentric, which cam, as the shaft revolves, serves to depress the said box and die plate once for each half turn of the shaft. When it is thought desirable to make the said heater box together with the die plate a fixture, and to force up the table against the die plate, he places the above described shaft, and the mechanism connected with it, underneath the table, which is then made free to rise and fall.—Patent completed.

1505 M. RUNKEL. *A new indicator for carriages.* Dated May 21, 1867.

The inventor claims, first, the application of the two instruments described—viz., the instrument (No. 1), which measures and marks the time by turning a dial, and the application of the moving hand provided with a pen or tracing needle, or any other equivalent, to mark on the dial; and the instrument (No. 2) which measures the distance by receiving its motion by the eccentric near the centre of the drawing wheel, and which transfers the mark of the distance to the dial of the time keeper, for the purpose and in the manner described. Second, the two instruments co-operating in connection with the outside signal and with the lever to be operated by the driver as described.—Patent completed.

1506 G. HURDMAN. *Improvements in charcoal box-irons.* Dated May 21, 1867.

This invention consists in making the lids or covers slide upon the bodies of the irons for the purpose of gaining access to the interior of the irons, or for closing the open tops thereof.—Patent completed.

1507 W. NICHOLS, J. BURNLEY, T. WILSON, and G. JACKSON. *Improvements in machinery for breaking or cutting flax, hemp, jute, and other fibrous materials.* Dated May 21, 1867.

The patentee claims the arrangements of machinery described for breaking or cutting flax, hemp, jute, or other fibrous materials in which the feeding and delivery of the material to and from the breaking wheels is rendered self-acting, thus increasing their production, reducing the amount of labour required, and rendering them safer to the persons employed in attending the same.—Patent completed.

1508 S. HOLT and G. HOLT. *Improvements in pickers and in the method of manufacture and apparatus employed therein.* Dated May 21, 1867.

This invention consists in using wire staples instead of the cramp wires now used in the manufacture of pickers, and which the inventors insert at the front and clench at the back part of the picker; and instead of boring the holes they stamp or press them. By this method there are no wire clenching at the front of the picker, as heretofore, which have been objectionable on account of the shuttle coming in contact therewith when the picker has become worn by the action of the shuttle tip.—Patent abandoned.

1509 C. H. SHURNHAM. *Improvements in the construction and application of certain mechanical arrangements to be adapted as a self-acting and ink supplying writing apparatus or fountain pen.* Dated May 21, 1867.

This invention consists of a combination of certain mechanical arrangements or parts to be adapted to the exterior of a hollow tube of a cylindrical, hexagonal, or other form, and which parts are capable of being taken to pieces and cleaned by any intelligent person, forming when put together again a self-acting and ink-supplying writing apparatus or fountain pen, furnishing a supply of ink greater or less according to the size of the tube. The invention is entirely free from any internal or external incumbrances, such as springs, plugs, pistons, syringes, valves, and other such obstructions to the free flowing of the writing fluid.—Patent completed.

1510 S. H. FOSTER and T. BUNNEY. *Improvements in means or apparatus for the manufacture of looped fabrics.* Dated May 21, 1867.

The object of this invention is to facilitate narrowing or widening of parts of looped fabrics during manufacture. For this purpose the hooks or needles employed are held together by screw or other pressures, and are capable of being independently removed or introduced at the parts desired, so that where narrowing is required the loops last formed in the needles or hooks to be removed may be lifted on to the adjoining hooks or needles, and when the holding pressure is relieved from the hooks or needles, those hooks or needles from which the loop or loops has or have been removed are withdrawn. The needles or hooks for the time withdrawn are placed at the end of the series of them, and then by screw or other pressure the whole are forced close together. To effect widening, the needles in use are at the part where the widening is to be effected, separated to the extent desired, and a hook or needle, or hooks or needles, are introduced, and so, until the desired widening is effected.—Patent completed.

1511 W. F. HENSON. *An improvement in rails for railways.* Dated May 21, 1867.

According to one arrangement the patentee forms double-headed rails for railways in a piece, with lateral or longitudinal webs or flanges, which may be plane, double bevilled, or corrugated. To secure rails made in this manner to the sleepers, he lays them in sleepers with longitudinal grooves, and passes bolts through the flanges into the sleepers; the rails can be turned by removing the bolts. According to another arrangement he forms flanges or webs to the rails by riveting on each side of the web of the rail pieces of [-iron, and then securing them in the sleepers as before described.—Patent completed.

1512 J. STENHOUSE and J. DUNCAN. *Improvements in the treatment of animal charcoal and in the apparatus employed therein.* Dated May 21, 1867.

This invention has for its object the cleansing of animal charcoal which has been used to decolorize syrups, &c., with the view to its re-use. The patentees take a quantity of this used charcoal, and wash it well with boiling water, and then introduce it into a suitable tank or cistern containing hot water slightly acidulated with nitric acid. When the charcoal and acid solution have been digested from half an hour to one hour, which is best effected by blowing steam into the mixture, the saline solution, consisting chiefly of nitrate of lime, is removed, and the charcoal repeatedly washed with either hot or cold water until all soluble impurities are removed. When dry it is ready to be re-burned and is again fit for use.—Patent completed.

1513 A. BARCLAY. *Improvements in apparatus for injecting and ejecting liquids and fluids.* Dated May 21, 1867.

This invention more especially consists in the construction of metallic packing applicable to the above-named apparatus, which may be employed to render steam-tight the moving or sliding joints in instruments of that class. Under one modification the packing consists of a metallic ring which is soldered or otherwise fixed to the tubular part; this ring is of a conical form, and several long narrow slits or openings are cut into it by a saw or otherwise. A second ring of corresponding shape is also soldered or otherwise fixed to the tubular part close to the first ring, the inner surface of the second ring being made to exactly correspond to the outer surface of the cut ring. This second ring is made by preference of thin brass, and its outer diameter is made slightly larger than the interior chamber of the outer part of the instrument, so that on being placed therein the rings are slightly compressed, and the outer ring is thus held against the inner side of the cylinder casing of the instrument to an extent sufficient to render the joint very effective and steam-tight, the inner ring acting as a spring forcing against the outer one. —Patent completed.

1514 A. V. NEWTON. *An improved central fire metallic cartridge, and apparatus for manufacturing the same.* (A communication.) Dated May 21, 1867.

This invention relates to a new and improved method of forming the shells or cases of metallic cartridges, and the invention consists in forming a chamber in the centre of the inner side of the cartridge head, in which the fulminate is securely fastened, and in the manner in which the fulminate is secured, and also in the tools or dies and punches by which the cartridge head is thus formed, and the fulminate secured. The invention is not described apart from the drawings.—Patent completed.

1515 O. WASSERMANN and J. H. HERBST. *A new method of refining the pig-lead scraped by means of rendline zinc, which is founded by the application for chemical apparatus.* Dated May 21, 1867.

This invention relates to the refining of lead which has been desilvered by means of zinc, in order to extract the zinc, and also the iron, antimony, or other metal which is

Digitized by Google

contained in the lead, and consists in submitting the red hot desilvered lead containing zinc, iron, and antimony to the action and effects of chloride of lead, which combines with the zinc and iron, whilst the lead of the chloride of lead is combined with the lead to be refined.—Patent abandoned.

1516 J. MABSON. *Improvements in sewing machines.* Dated May 21, 1867.

This invention is not described in detail apart from the drawings.—Patent completed.

1517 D. ADAMSON. *Improvements in furnaces for heating the air stoves of blast furnaces, and for other purposes, and in utilizing the products of combustion from such stoves.* Dated May 22, 1867.

This invention consists in certain improved furnaces for heating the air stoves of blast furnaces for steam boilers, and for other purposes. These furnaces consist of diagonal grate bars placed in a fire brick or other chamber, or partly in the chamber, or partly in the stove or boiler to be heated, or entirely on the stove or boiler, and of a hopper to supply the fuel, and a swing frame or falling grid to discharge the clinkers. The invention also consists in utilizing the products of combustion from the air stoves of blast furnaces by drawing or forcing them through a series of flues or drying stoves, kilns, or ovens to evaporate moi sture from ironstone and other minerals, and for heating and drying purposes.—Patent completed.

1518 J. COLLINS and J. SMETHURST. *Improvements in machinery for dressing hides.* Dated May 22, 1867.

This invention relates to the dressing of hides of leather and is designed, principally, to facilitate the operations of "staking," "shaving," and "buffing," and is as follows:—At or about the centre of the machine an upright frame is fitted to slide in standards, or in the framing of the machine, and to the upper part of the said frame a suitably formed knife is attached over which the hide is to be drawn. The edges of the hide are temporarily fixed by means of jaws, or otherwise, to the upper part of two rocking levers, one of which is situated on each side of the knife, the lower ends of the levers being jointed to the opposite ends of a lever which may be situated under the bed of the machine, and which also has a rocking motion on a bearing at or near its centre to allow the side levers to rise and fall. The said vertical side levers are connected to one another at a point between their fulcrums and the points of attachment to the hide by means of rods or bars sliding one upon another, or by other suitable means, to admit of the upper ends of the vertical levers being separated less or more to suit the varying widths of the hides.—Patent abandoned.

1519 J. CARTLAND and H. BOLD. *Improvements in ornamenting certain kinds of bowls of castors for furniture.* Dated May 22, 1867.

This invention relates to castors made of china or earthenware, and consists in ornamenting them by giving to them a lustrous or metallic appearance, the lustre either being white and resembling silver, or having a yellow tint and resembling gold.—Patent completed.

1520 J. HARGREAVES and T. ROBINSON. *Improvements in the manufacture of steel and soft iron from cast iron.* Dated May 22, 1867.

This invention consists in the use of any of the salts which yield oxygen on the application of heat, such as the nitrates, chlorates, bromates, manganates and stannates mixed or in combination with any of the oxides of iron or manganese, or any other suitable powdery or granular substance, as agents to act on fused or molten cast iron, to burn out therefrom at any desired speed the excess of carbon in and at the same time to remove other impurities from the said cast iron, and thereby convert it at one operation into steel or soft iron.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated September 25, 1867.

2706 J. Kirk and J. Kirk, jun., The Park Side, Lenton, Nottinghamshire, lace manufacturers. Improvements in the manufacture or production of lace or weavings made on bobbin net or twist lace machines.

Dated October 24, 1867.

2999 E. M. Palliser, Newcastle-upon-Tyne. Improvements in magazines or reservoirs for containing explosive compounds or liquids, and gunpowder.

Dated November 13, 1867.

3215 U. P. Wurlein, Rue Christophe, Berne, Switzerland. Improvements in instruments for joining blind cords and other cords.

Dated November 27, 1867.

3359 E. Belknap, Mortimer-street, Cavendish-square. Improvements in the treatment of the solution of malt for brewing.

Dated December 6, 1867.

3471 S. Goldstein, Manchester, merchant. Improvements in various portions of ladies' and gentlemen's wearing apparel.

Dated December 9, 1867.

3495 E. Keirby, Rochdale, Lancashire, india-rubber merchant. Improvements in elastic packings for the pistons of steam engines and for other purposes, and in the machinery employed in the manufacture of such packings.

Dated December 13, 1867.

3545 G. Marson, Eagley, Bolton, Lancashire. Certain improvements in the method of and means for retaining the outer ends of tapes, ribbons, and other similar narrow fabrics and paper.

3547 W. Mellwraith and J. Bonner, Glasgow, Lanarkshire. Improvements in apparatus to be applied to looms for weaving.

3549 A. Bullough, Blackburn, Lancashire, cotton manufacturer. Improvements in looms for weaving.

3551 T. Pedardy, 22, Greville-street, Hatton-garden, surgical bandage and instrument maker. Improvements in surgical appendages, to consist of a corset and abdominal supporter combined, also to serve as a truss in cases of umbilical and ventral hernia.

Dated December 14, 1867.

3555 F. Berry, Calderdale Ironworks, Sowerby Bridge, engineer and tool-maker. A self-acting metal breaker.

3557 J. Sharples, shuttle-maker, and J. Schofield, cabinet-maker, Blackburn, Lancashire. Improvements in shuttles employed in weaving, and in bobbins used therewith.

3559 J. Hargreaves, Appleton-within-Widnes, Lancashire, analytical chemist. Improvements in the manufacture of soda and potassa.

3561 J. H. Kidd, Bangor Iscoyd, Flintshire. Improvements in brattice cloth and its manufacture.

3563 E. H. Bentall, Heybridge, Maldon, Essex, agricultural implement manufacturer. Improved apparatus for controlling the draught of water from constant supply pipes.

3565 O. Hollingworth, 69, Pilgrim-street, Newcastle-on-Tyne, civil engineer. Improvements in feeding furnaces for prevention of smoke and economizing fuel.

3567 E. and A. Tatham, Nottinghamshire, manufacturers. Improvements in the manufacture of sinkers for hosiery and other machines.

3569 L. A. W. Lund, Chandos-street, St. Martin's. Improvements in studs, stud-buttons, and solitaires.

Dated December 16, 1867.

3571 J., J., and J. Booth, Rodley, Leeds, engineers and millwrights. Improvements in means or apparatus for effecting the cutting or dressing of stone.

3572. J. E. A. Gwynne, Essex-street, Strand, engineer. Improvements in sinking tubes or cylinders for obtaining and raising water, and in the apparatus for effecting the same.

3573 W. Huskisson, jun., 76, Swinton-street, Gray's Inn-road, manufacturing chemist. Improvements in the manufacture of soda and other aerated waters, and in the manufacture of aerated bread.

3575 J. M. Shackleton, Accrington, Lancashire, cotton manufacturer. Improvements in the manufacture of umbrellas.

3577 W. H. Kerr, Clontarf, Dublin, china merchant. Improvements in the preparation of material to be used in the manufacture of porcelain and pottery.

3581 W. Huskisson, jun., 76, Swinton-street, Gray's Inn-road, manufacturing chemist. Improvements in the manufacture of bicarbonate of potash and soda.

Dated December 17, 1867.

3583 T. V. Macintosh, Port Glasgow. Improvements in machines for making drains or trenches.

3585 W. Simons and A. Carmichael, Renfrewshire. Improvements in moulding, and in the machinery or apparatus employed therefor.

3587 E. M. Du Boys, government engineer, Paris. Improvements in liquid meters or apparatus for measuring and registering the volume of water or other liquid flowing under pressure through pipes or ducts.

3589 F. L. and C. L. Hancock, Dudley, Worcestershire. Improvements in and connected with propellers, and in arrangements for propelling vessels.

3591 W. E. Newton, Chancery-lane, civil engineer. An improved method of and apparatus for the manufacture of tinned leaden pipes. (A communication.)

Dated December 18, 1867.

3595 J. Patterson, Hull, Yorkshire, engineer. Improvements in capstans.

3599 J. Hall, Barrhead, Renfrewshire. Improvements in furnace grates and casings. (A communication.)

3603. O. A. Hebert, New Millman-street, watch-maker. Improvements in musical boxes.

Dated December 21, 1867.

3628 E. Lord, Todmorden, Yorkshire, machine-maker. An improvod mode of reducing the friction of revolving and sliding surfaces.

3632 J. Hadley, City Flour Mills, Upper Thames-street. Improved apparatus for cleaning grain or seeds, and reducing the same to meal or flour.

3634 W. Hurst, Hamer Hall, Rochdale, Lancashire, cotton spinner, and J. H. Wilson, Cornholme Mill, Todmorden, Lancashire, bobbin manufacturer. Improvements in or applicable to flyer, throstle, and doubling frames and machines of like character.

3636 E. and A. Ludlow, manufacturers, Birmingham. Improvements in machinery for the manufacture of cartridge cases.

3638 I. Pick, 5, Falcon-square, City. Improvements in the construction of bags, portmanteaus, and other similar articles.

Dated December 23, 1867.

3640 J. Rowe, Wrexham, Denbighshire, civil engineer. Improvements in the construction of miners' safety lamps.

3642 C. W. Lancaster, New Bond-street, gun-maker. Improvements in the construction of cannon and other firearms.

3644 R. Crawshaw, Colne, Lancashire, shuttle peg-maker. Improvements in shuttles for looms for weaving.

3646 H. F. Bengough, Clifton, Gloucestershire. Improvements in tobacco pipes.

3648 S. Salter, Stroud, Gloucestershire. Improvements in the construction of rotary engines.

3650 W. H. Chase, jun., Brixton-hill, manufacturer. Improvements in the construction of couplings for driving belts.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated December 31, 1867.

3712 J. Novikow, Briansk, Orel, Russia. An improved apparatus for drawing and spinning hemp, flax, and other fibrous materials for making ropes and cables.

LIST OF SEALED PATENTS.

Sealed December 24, 1867.

1870 J. Gabbott
1871 W. Bullough
1884 W. Marshall
1886 C. O. Heyl
1892 C. Brown

2071 J. L. Norton
2184 T. Jones
3227 J. Combe

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," January 7, 1867.

2410 J. G. Marshall. Detergent processes.
2425 A. and E. Wigzell. Juckes' furnace.
2426 J. Phillips-Smith. Agricultural implements.
2431 W. R. Lake, Cartridges. (A communication.)
2435 W. C. Thurgar. Regulating the supply of gas.
2444 M. A. Soul. Fastening iron bands. (A communication.)
2450 W. Pedder. Brushes.
2461 J. Douglas. Ventilating and regulating the draft of close fire ranges.
2463 J. and G. W. Dyson and S. Martin. Cutting up iron and steel rails and rail ends.
2465 W. Muir. Starting, propelling, and stopping railway trains and ships.
2480 D. Nicoll. Electric telegraph conductors.
2486 H. Vallance. Window fastenings.
2493 P. F Lunde. Obtaining extracts from vegetables.
2496 E. T. Archer. Spring mattresses.
2522 F. Versmann. Manufacture of varnishes.
2537 D. Payn. Printing machinery.
2541 J. Whitham. Machinery for puddling.
2546 W. E. Gedge. Indigo colouring matter. (A communication.)
2549 F. Tolhausen. Disinfecting fecal and manuring matters. (A communication.)
2565 J. Whittome. Baling presses.
2575 J. Davies. Manufacture of salt.
2613 W. Brailsford and J. Gadsby. Manufacture of lace.
2640 W. W. Gibson. Decorticating and cleaning cereals.
2650 S. Dreyfous. Bread ovens. (A communication.)
2698 J. Musgrave. Stable fittings.
2749 T. Weston. Ornamental metallic tubes.
3003 G. J. Gunther. Plating ships of war.
3103 T. Wright and I. Fox. Plain and fancy weavings.
3322 S. Amphlet and J. B. Fenby. Ruling ornamental patterns.
3345 W. R. Lake. Fire arms. (A communication.)
3346 W. R. Lake. Electric telegraph apparatus. (A communication.)
3348 C. T. Higginbotham. Furnaces.
3384 J. Baylis. Chemical preparation for preparing mixed textile fabrics.
3469 P. G. L. G. Designolle and J. Casthelaz. Explosive and fulminating powders.
3490 J. Beatty. Candle dipping machine.
3500 W. R. Lake. Excavating machines.
3501 H. Bessemer. Firebricks, tiles, and other articles employed in building.
3526 J. R. Baillie. Caissons.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

19 E. Keirby
24 D. Vericchio
26 G. Kent
27 N. Thompson
34 J. Skelton

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 17, 1868.

THE DISPOSAL OF SEWAGE.

LOCAL boards and provincial authorities have yet to solve the problem, involving, as the unknown quantity, the disposal of their sewage. Discharge it into the rivers they must not; utilize it they do not; get rid of it they must. The evil day may be put off for a time; in fact, procrastination is an essential adjunct to all corporate proceedings, except when they are characterized by an equally injurious rash and ill-judged celerity. It is not that they are puzzled to decide whether the scheme for utilization should be carried out upon the simple plan of gravitation, or whether their choice should rest upon that necessitating the more expensive accessories of engines and pumping stations. The place where the shoe pinches is "the place where they are to put it." Unless actuated by interested motives, no one, it will be at once conceded, would view with pleasurable feelings the irrigation of their fields with sewage matter. At the same time, upon the broad principle of the public welfare, which has been so scandalously abused by railway companies, private prejudices and individual antipathies must not weigh down the balance when the health of the community is placed in the descending scale. With the express purpose of obviating mere personal interests an Act was passed last session, somewhat similar to that governing the legislation of private bills, and authorizing the compulsory purchase of land that may be deemed the best adapted for carrying into execution a proposed scheme of utilization of sewage. So far, so good; but here, as will be presently seen, ends all similitude between the compulsory purchase of land for railway or other engineering purposes, and for the disposal of sewage. In the former instance, the claim to the land is made by one party, the opponents constituting the other. In the latter, the case bears a very different aspect, and it is easy to perceive how the best devised scheme might be rendered perfectly abortive if against the private interests of any influential local authority.

Although nothing, comparatively speaking, has been effected anywhere with respect to the real utilization of sewage, yet it is a problem that must be solved before long. True, that in the majority of instances, nothing short of a raging epidemic directs attention to any particular district, but as the population of the country increases, and sanitary measures continue to remain "in statu quo," the opportunities for observing what the results of a neglect of them inevitably tends to will become more frequent. The sewage of London is, at least, got rid of, although it is not yet utilized, and the Thames at last rolls its unpolluted waters through a granite-bound channel. What has been accomplished with respect to our principal river must be carried out with equal force with regard to its tributaries and our other national streams. Instead of discharging sewage matter into rivers by thousands of gallons, it has been decided that the proper disposal of it is to apply it in one of different ways to land, and the question at issue is where to procure the land requisite. We may assume as a rule liable to exceptions that until the population of a town reaches to 8,000 there is no absolute necessity for the execution of a regular scheme for the utilization of its sewage. Taking one acre of land as a minimum required for every 150 heads of the population, we should need 66 acres to utilize the sewage of a town containing 10,000 inhabitants. This, it will be perceived, is a very different matter to the contingencies attending the construction of a railway, which demands but a small strip of land throughout its general course, and only a slightly additional amount for the erection of its stations. A proprietor that would put up with the one would be inclined to wage war "a la outrance" with the other. Moreover, although at one time the locomotive was unjustly regarded in the light of an almost intolerable nuisance, yet it is now universally looked upon as the herald of peace and civilization. One feels, as it were, at home if, when visiting some out-of-the-way kind of place, the whistle of the engine can be heard, and the escaping steam seen in the distance. It is not too much to say that the irrigation of land by sewage may be justly termed a nuisance, not in a very grave degree, or by any means in an injurious sense, so far as health is concerned, but still, as we have before mentioned, no one except for interested motives would like to witness it meandering over his fields.

So soon as a town elects to place itself within the jurisdiction of the "Public Health Act," by virtue of the provisions in that Act, it proceeds to constitute from among the ratepayers a "local board," and vests in the members for the time being of that corporate body the authority in all matters connected with the arrangement of the drainage and the disposal of the sewage. These "local boards" retain in their constitution a strong element of Bumbledom, and are disposed to do everything in the cheapest manner possible, laying to their souls the flattering unction that they are bound to be as careful as possible of the money of the ratepayers, totally oblivious of the fact that these carefully-considered individuals are frequently mulcted to a large amount to make good the deficiencies and blunders of their representatives. Government has, in fact, only done the thing by halves. Once having recognized the necessity of abolishing the "ancien regime," and having set its face against the abominations of cesspools and the pollution of streams, it should have gone a step farther. It appears paradoxical to grant powers of compulsory purchase of land, in order that the best scheme for utilization of sewage might be carried out, and yet to leave it in the hands of local authorities to reject the best scheme, to carry out an inferior one, and to exercise the powers in a manner foreign to their original signification. Considering to what extent building operations are now everywhere progressing, and how enormously the bare possibility of such a contingency enhances the value of land, it is manifest that there is a fruitful source of litigation opened up in connection with the enforcement of compulsory powers. Nothing is easier than for a proprietor to allege, when his land is demanded for the disposal of sewage, that he has set it apart for building purposes, and it will probably require a jury to settle the amount that is to be paid to him. We are not aware, owing to the absence of all precedent in the matter, whether the law is the same with respect to sewage works as with those of a railway. In the latter case, the opponent is not permitted to show that the line might have been more advantageously laid out, so as not to affect his interests or to touch upon his property, but must oppose it "in situ," as it were, and deal with the injury as it stands. It remains to be seen whether, in the event of compulsory powers being exercised with regard to sewage works in behalf of an inferior scheme, it may not rest with the proprietor of the land to traverse the proceedings of the local authorities, and show proof that a more advantageous scheme might be projected, which would not entrench upon the property that had been scheduled. It is bad enough for a landed proprietor to be compelled to cede unnecessarily a portion of his territory to the caprices of a leviathan railway company, but the case becomes aggravated when instead of a few acres perhaps a hundred are seized upon for the disposal of so unpleasant a substance as sewage matter. A more satisfactory course of action would be for the surveyor to the Board, or whatever may be the constituted local authority, to prepare what he considers the best scheme, to submit it to the investigation of an officer of the Board of Trade, who, on approval of it, would order the proper steps to be taken to procure the land necessary, without the slightest regard whether that land was the property of a member of the Board or of any one else.

TELEGRAPHIC COMMUNICATION WITH ABYSSINIA.

WHATEVER difficulties we have on hand at home, there can be no doubt that the subject upon which at this moment the greatest interest is felt by the majority of Englishmen is the present state of affairs in Abyssinia; and the great want is to have from day to day intelligence without uncertainty or delay. It may justly be asked why we do not get this. We feel that the time has arrived when that agent, which has proved a most valuable auxiliary in war, as well as in peaceful and scientific pursuits, should be considered by those who have to calculate the expense of carrying on wars in foreign countries. Those who are responsible for the management of the war, which may now be at its height, in the comparatively unknown country of Abyssinia, ought at the present moment to be able to say, as Marshal Vaillant did, when asked for some particulars connected with the telegraph cable laid in the Black Sea during the Crimean war:—"I send my dispatch to the General, and I have an answer sooner than I should have if by letter from a town halfway from here (Paris) to Lyons, Bordeaux, or Strasburg. I have not yet recovered my amazement at this prodigy." The late Lord Lyons also, speaking on the same subject, gave it as his opinion, that the laying of the Black Sea telegraph lessened the duration of the war by two or three months, by affording a means of rapid communication with the Crimea.

With these facts on record, we are quite at a loss to understand why, when it was found absolutely necessary to go to war with Abyssinia, a submarine telegraph cable was not immediately ordered to be laid in the Red Sea from Suez to Aden, and thence to Bombay—bringing the Commander-in-Chief and forces in Abyssinia, and those in Bombay and Aden on one side, within twelve hours' communication with Suez, Alexandria, Malta, and London on the other. The importance of such a system must be thoroughly understood by everyone who regards the Abyssinian question with interest, and we feel that a grave responsibility rests upon those in authority, for not availing themselves of the opportunity of carrying out this desirable object; for it would not only have assisted materially in this present disastrous war, but it would have accomplished the long cherished idea of placing our Indian dependencies in direct communication with London by a telegraph cable, remaining a peaceful agent long after the Abyssinian war is forgotten.

We cannot think that the cost of such a line would for a moment be entertained as a bar to its adoption, and, therefore, we will at once dispense with that. There is an apparent cause for doubt and excuse, viz., that the scheme was tried about ten years ago, and then proved a decided failure. To those who at the present time put forth such a plea, all we can say is, that they have not followed the course of events since that time. It is true—to their credit be it spoken—the present Government did, at the time mentioned, make an attempt to establish direct communication between London and Calcutta, but the whole thing proved a failure, and why? Simply because necessary and proper precautions were not taken to ensure success. A private company made the same mistake about the same time, in their endeavour to complete telegraphic

Digitized by Google

communication between this country and America; but, after praiseworthy perseverance they have at length overcome all difficulties, gained a glorious triumph, and are now receiving a well-deserved reward. What has been done in the Atlantic can as certainly be done in the Red Sea, and never was there a more fitting time for the work to be carried out. Previous to the laying of the Atlantic Telegraph Cable, there were those who were daily putting forth fabulous statements in order to frighten sanguine persons, and we do not doubt that at the present time there are many who use the same means to delay the carrying out of the line to India. But those who are thoroughly acquainted with the question—and, therefore more competent to give an opinion—are confident that there is no difficulty whatever, and that a direct line from London to Calcutta can be established and maintained with less difficulty than the present line from London to New York.

We believe an eminent firm has made very reasonable proposals for carrying out this much-desired work, and are ready to stake not only their well-earned reputation but also a large amount of capital on the result. It would be satisfactory to know that the Government was fully alive to the importance of such a line, and we hope soon to hear that they have arranged for the work to be carried out in such a way as will redound to their own credit and that of the nation.

PHOTOGRAPHY.

NEW BOOK ON PHOTOGRAPHIC OPTICS.—CEMENTING TRANSPARENCIES.

A NEW book on photographic optics, being a translation of the work by Dr. Van Monckhoven, has just been published by Mr. Hardwicke, of Piccadilly. Probably no branch of science exhibits so much poverty in standard works as photography, Hardwich's "Photographic Chemistry" standing almost alone in this field of research. The new optical book just mentioned, helps to fill up a very great blank, but does not do it in so complete a manner as desirable, for the original work was published two or three years ago, and new lenses of considerable photographic interest have been since introduced into the market, but are not noticed in this English translation. In issuing another edition, it will be more judicious to follow the subject down to the latest date. Nevertheless, it is pleasing to see, at last, a book devoted exclusively to photographic optics, for it is the first that has been printed in this country.

As it is known that collodion positives on glass, properly taken, and well varnished, are very permanent, some attention has of late been drawn to different methods of cementing a second sheet of glass over the picture by Canadian balsam. No reason is known why a picture thus embedded in resin between two plates of glass should not last for centuries; moreover, transparent positives on glass are the most delicate and beautiful pictures it is possible to produce by photography. Three methods of cementation are in vogue, but it is too early yet to speak of their comparative merits.

The first of these has been extensively practised by Mr. John Traill Taylor. He mixes any liquid hydrocarbon, preferably benzole, with Canadian balsam, till the latter is of about the consistency of castor oil. A few drops of this, free from air-bubbles, are allowed to fall upon the centre of the photograph, and then the second sheet of well-cleaned glass is gently let down on the lower picture. By pressure, the balsam is made to fill up the space between the two plates, and the superfluous liquid squeezes out at the edges, and falls upon a sheet of paper on which the lower glass is laid. The cemented picture is then placed for half an hour or more upon a warm iron plate, during which time it is subjected to pressure, which may be conveniently applied by means of a warm flat iron placed upon the upper sheet of glass. After being thus subjected to moderate heat under pressure, the two glasses will be found firmly cemented together, and the superfluous resin spread over the edges and faces of the glasses may be removed by rubbing with a little oil of turpentine.

Another method of cementing photographic transparencies is that practised by Mr. Warren De La Rue, F.R.S., to preserve the photographs of the moon, taken by the aid of his reflecting telescope at Cranford Observatory. The pictures are cemented by means of the force of capillary attraction. By his plan, a flat polished plate of brass, supported by four levelling screws below the corners, is heated by means of gas jets underneath. The plate is then fixed accurately in a horizontal position by means of the screws, aided by a spirit level. The collodion picture on glass is then laid face uppermost on the brass plate, and a second but smaller piece of clean glass is next laid face downwards over the picture. The upper plate touches the lower one at one of its edges only, because a piece of thin paper is pushed about 1-8th of an inch under the opposite edge. When this arrangement has been made, and both the plates are very warm, a few drops of clear Canadian balsam are allowed to fall on the lower plate, just where it is touched by the edge of the upper one. The balsam is at once further liquefied by the heat, and, by capillary attraction, begins slowly to travel between the two plates of glass, pushing the air away before it. In the course of ten minutes, if the plates are not very large, the balsam will have travelled over two-thirds the space between them; then the slip of paper can be removed, and in a very short time the whole space will be filled by the balsam. The two plates should then be left on the slab of brass for a little while to bake, that the heat may drive off some of the essential oils in the balsam. This process is slow, but very safe, because there is no danger of enclosing air bubbles, which are very unwelcome opponents of cementation manipulations.

A third method is that used by Mr. G. Wharton Simpson, and by many practical opticians. The essential oils in pure Canadian balsam are driven off by the long application of moderate heat, not much above that of boiling water. Balsam thus treated will solidify on cooling, but when wanted for use should be again liquefied by warming. To cement the picture, a flat sheet of thin iron, standing horizontally upon four legs, is heated underneath by little jets of gas. The picture is laid, collodion side uppermost, on the hot iron plate, and a few drops of the balsam are then allowed to fall upon the centre of the glass. The second piece of glass, previously warmed, is then placed on the lower one, and the balsam pressed out, as in the first process, till it fills all the space between the glasses, which are next allowed to cool. When cold, they will be found firmly cemented together, and a neat way of finishing off the picture is to send it to a glass-cutter, to grind down the edges, till the whole resembles a single sheet of glass with a picture embedded in its centre.

The shadows of photographic transparencies contain much more silver than the shadows of positives upon albumenized paper. Added to this fact, a good transparency may be taken without the film in any way coming in contact with its old enemy "sulphur." When, in addition, a picture of this kind is thoroughly sheltered from atmospheric influences by cementation between two plates of glass, there are strong reasons for confidence in the durability of such photographs. Yet, no pictures of this kind are on sale in London. Those stereoscopic transparencies on glass, sold by our leading photographers and opticians, will be found, on dissection by a penknife, to consist of two plates of glass, not cemented together in optical contact, but simply held together by means of paper pasted round the edges. Nevertheless, most of these are very permanent, more especially those which were taken without the application of any chemical containing sulphur, and which were well washed and dried before varnishing.

ON SOME RECENT IMPROVEMENTS IN ANALYTICAL CHEMISTRY.

1. A METHOD OF QUALITATIVE ANALYSIS WITHOUT THE USE OF SULPHURETTED HYDROGEN OR SULPHIDE OF AMMONIUM.

THE pursuit of analytical chemistry can never be a drawing-room amusement; but one of the greatest obstacles to its study in an ordinary dwelling-house has been removed by Zettnow, who has devised a scheme of examination for bases without the use of the offensive reagents named in our heading. We propose to give a short account of the author's plan, which, it will be seen, is applicable to the analysis of solutions containing all the most frequently occurring bases.

The first step is the usual one of adding hydrochloric acid to the solution. A precipitate on this addition will be either chloride of lead or silver or subchloride of mercury, which may be separated in the way directed in all books on analysis. Zetnow's next step is to add sulphuric acid to the filtrate, by which lead, strontia, and baryta are thrown down as sulphates with the lime, in part, if present. The mixed precipitate when washed with water will give up the sulphate of lime; sulphate of lead may be removed by a solution of tartrate of ammonia. Sulphates of strontia and baryta may remain. These will be found difficult to separate, and the experimenter, unless a practised analyst, must content himself with identifying the bases by their blow-pipe reactions.

About a quarter of the liquid separated from the sulphates is now precipitated with excess of baryta water and boiled; ammonia, if present, will be evolved, and may be recognized by the usual tests. The excess of baryta must afterwards be precipitated by carbonate of ammonia, the solution filtered, the filtrate evaporated to dryness, and the residue calcined. In this residue potash or soda may be found.

Another portion of this solution must be set aside for the examination for zinc, as described hereafter.

The remainder of the liquor separated from the sulphates (having, of course, an excess of sulphuric acid) is placed in a flask furnished with a drawn-out tube, and treated with metallic zinc. Arsenic and antimony will be detected in the hydrogen evolved; and, at the same time, tin, antimony, mercury, copper, cadmium, and bismuth will be thrown down by the zinc in the metallic state. This precipitation is facilitated by placing a strip of platinum with the zinc in the solution.

The metallic precipitate so obtained in the flask is treated with nitric acid, in which all but the tin and antimony will dissolve. These will remain in the form of stannic and antimonic acids, easy to recognize and separate by their respective reactions.

A portion of the nitric acid solution is specially examined for mercury with chloride of tin. The remainder is boiled with caustic soda; the precipitate so obtained is washed with ammonia and chloride of ammonium. Bismuth will be left undissolved in the form of hydrated oxide; cadmium and copper will be found in the ammoniacal solution. The latter will be recognized by the blue colour of the solution and the precipitate with yellow prussiate of potash; the former will be precipitated as white hydrated oxide by an excess of caustic soda.

The solution from which zinc precipitated the other metals is now oxidized by boiling with a few drops of nitric acid, and a portion of the solution is tested for iron with sulpho-

Digitized by Google

cyanide of potassium. Another portion is neutralized with ammonia and shaken up with a little carbonate of baryta. Hydrated oxides of chromium and alumina are thus precipitated. The precipitate is boiled with caustic soda, permanganate of potash being added to further oxidize the chromium. Chromic acid and alumina will be found in the filtrate.*

The solution separated from the carbonate of baryta, together with the excess of baryta, may still contain manganese, lime, nickel, cobalt, and magnesia. It is first treated with sulphuric acid to eliminate the baryta; the filtrate is then treated with carbonate of ammonia, which will precipitate the manganese together with the lime. The filtered liquor may now contain magnesia, nickel, and cobalt. The first will be thrown down by the addition of phosphate of soda. The filtrate from the ammonio-magnesian phosphate is now evaporated to dryness, and the residue dissolved in hydrochloric acid. Cobalt is then sought for by nitrate of potash and acetic acid, and nickel by caustic soda after the cobalt, if present, has been separated.

Zinc is now the only common base which remains, and as this has been added to the solution in the course of the later operations, it must be sought for in a portion of the liquid set aside after the separation of the chloride and sulphates. The liquid is first boiled with caustic soda, then filtered, and the filtrate treated with carbonate of ammonia and chloride of ammonium, and boiled again until ammonia is no longer disengaged. Filter again, and test the filtrate for zinc with ferridcyanide of potassium.

The above is the systematic course of examination for bases proposed by Zettnow. It can hardly be considered perfect, but it possesses some features of interest, and may be commended to the notice of amateur chemists, and even to practical chemists, when sulphuretted hydrogen is not accessible.

2. A PROCESS FOR THE DETERMINATION OF PROTOXIDE OF IRON IN SILICATES NOT SOLUBLE IN ORDINARY ACIDS.

Professor J. P. Cooke has devised a method by which this determination can be effected with great accuracy. The novel feature in the process is the solution of the iron oxides by prolonged digestion of the silicate in sulphuric and hydrofluoric acids out of contact with the atmosphere. Ten or fifteen grains of the finely powdered mineral are mixed with some sulphuric acid (sp. gr. 1·5) and a little hydrofluoric acid in a platinum crucible, which is set on a copper water bath. This bath is provided, firstly, with a tube through which a supply of water can be kept up from a Marriotte's bottle, and so the water maintained at a constant level; secondly, with a tube to carry off waste water; and, thirdly, with another tube connected with a carbonic acid apparatus, by which a stream of this gas may be carried under an inverted glass funnel set on the cover of the bath. A groove is made in the cover to receive the rim of the funnel, and this groove being filled with water, an air-tight joint is made. A current of carbonic acid being started, the platinum crucible is set under the funnel and the gas lighted. As soon as the water boils the supply of carbonic acid may be stopped, since the atmosphere of steam will be sufficient to protect the iron solution from oxidation. In this manner the digestion may be continued until the decomposition of the mineral is complete. The current of carbonic acid must then be re-established and the contents of the crucible allowed to cool. The solution is now diluted with water to 500ccs., and the protoxide of iron is determined by a standard solution of permanganate of potash. This process may be applied to the assay of iron ores; and hydrofluoric acid may be usefully employed in a large number of analytical operations.

* If the liquid contains phosphoric or boracic acid, the author adds some perchloride of iron before precipitating with carbonate of baryta.

ELECTRICITY AND TELEGRAPHY.

THE Electric and International Telegraph Company have lately been trying some experiments with a small magneto-electric machine of Mr. Wilde, of Manchester. It is in construction similar to that which we have lately described. Twenty horse-shoe permanent magnets are attached to a "magnet cylinder," within which revolves an armature on Siemens' principle. At one end of the armature is a commutator for producing a uni-direction current, at the other end a small pulley driven by a strap from a larger pulley fixed on the shafting of the machinery used at Telegraph-street for the pneumatic apparatus. The induced electricity from the armature was applied to the working of several telegraphic circuits instead of the ordinary batteries. It has been tried for some days as an experiment, and then discontinued, we believe, from the result not having been quite as successful as was expected. The power obtained from it was sufficiently adequate for the work required, but the supply was not always regular and constant, probably due to the too great rapidity of the armature and the irregularity of the contacts of the commutator. With several alterations, we may fairly expect to see this machine become of some practical use.

The French Government have lately issued a series of telegraph stamps, their use dating from the first of the year. They are of the respective values of 25 and 50 centimes and 1 and 2 francs. Stamping despatches will enable the sender to leave his message or have it sent to the office as an ordinary letter, but in cases where the message is in a foreign language (other than French) it must be accompanied with a translation. No message can be forwarded in this manner when the charge is above ten francs; in that case the usual mode of payment over the counter must be adopted. We are glad to see that our neighbours have carried out a plan that has been received for so long a time with much favour in our country.

We lately noticed the working telegraphic circuits between Paris and Lyons on an automatic system. Experiments have been going on for some time at the Electric Telegraph Company's station, Telegraph-street, upon Professor Wheatstone's improved apparatus for sending messages automatically on the Morse system. His instruments have been used for working between London and Newcastle, and have been highly successful. The paper has to be prepared by punching holes in it; this paper passes through the transmitter, sending currents according to the position of the hole. The currents so sent act upon the polarized magnet of the receiving instrument, causing the armature to record upon ordinary paper by means of an ink marker the necessary Morse signals. The conventional signals are transmitted by an ordinary key and recorded upon the same receiving instrument. The speed can be varied at will, from about 40 words per minute upwards. As there are many points in this instrument of great interest and novelty, we simply allude to it briefly here, hoping shortly to place a full description of it before our readers.

We regret to announce that the large cable connecting Dunwich (Suffolk) and Zandvoort (Holland) has lately been broken. The fault is supposed to be about midsea. This is the first time this cable has been broken so far away from land. The Electric and International Company having their telegraph steamer always in readiness, we do not anticipate that there will be much delay.

In lately carrying out the repairs to one of the Submarine Company's cables off Cape Grinez, all the work that their engineer, Mr. France, had succeeded in doing was undone in a somewhat unusual manner. He had succeeded in buoying both ends, when a number of French mackerel boats cast their nets tideward of him. A strong tide flowing at the time soon brought them down upon his steamer, carrying away his buoys, and compelling him to weigh anchor and run for it. Now, this was done in broad daylight, and with a steamer carrying the usual Board of Trade signal for a telegraph steamer. Something should be done to make this signal more generally known, for with the number of submarine cables requiring now and then certain repairs, it is excessively annoying to find all one's work (particularly in the winter time) undone, and one compelled to postpone further work until the fishing was over.

We remember a previous case off Dover in the first repairs to the Calais cable, when the buoys were all swept away in a similar manner.

In confirmation of Gassiot's experiment, that electricity will not pass through a perfect vacuum, Messrs. Alvergniat have constructed a small apparatus which proves the same in an easy manner. M. Gassiot formed his vacuum by filling the tube with carbonic acid and gradually absorbing it by the agency of potash; they, however, produce a vacuum by means of their own mercury pneumatic machine. When by aid of this machine the vacuum is brought as high as possible in the tube, it is placed over a special lamp, and gradually heated until it is brought to a red heat. This is done slowly and gradually, so as to prevent any damage to the tube. The pneumatic machine is still applied, and the vacuum made more perfect. The vacuum in a tube so prepared is found so perfect that even with platinum wires placed at a distance of only ·078 inch from each other no discharge passes. These tubes, Messrs. Alvergniat claim, are prepared in an easier and more rapid manner than those on M. Gassiot's plan.

The electrical systems of communication between passengers and guards of trains are now being under a severe test, in order that they may be finally reported upon. The Exeter express fitted up with communication has now been running with success for several years, but to test it finally it has been determined to start the train entirely by means of this communication from all stopping stations, which will be done by the head guard in the hind van signalling on the bell fixed on the engine to the driver; special instructions are issued for the noting of any irregularity of the communication. The Midland Railway has had their Leeds express fitted up in a somewhat similar manner, but with a "look out" signal on the engine instead of a bell. This train is now running daily, and is regularly started by means of the communication. It is accompanied, we believe, by an extra guard, whose duty is to specially report upon the working of the communication. It has been running with the greatest success, and from an inspection of it we do not see why it should not continue to do so.

The Atlantic Company have issued a prospectus in order to obtain the necessary capital to buy back their cables from the Anglo-American Telegraph Company; they require for this purpose a sum of £1,300,000. Negotiations were set on foot for the amalgamation of the two companies: these, however, were unsuccessful; they look forward to a large business, "with a revival of trade a very large increase may be expected to take place in the receipts. The whole of the present business can be performed by a few hours' daily working of one cable only, thus leaving a very large margin of working capacity to meet the requirements of increasing trade."

Messrs. Siemens, who have for some time past been actively engaged in negotiating for permission to erect two wires through Europe and Persia to join on to the Government Indo-European, have already obtained concessions from the Prussian and Russian Governments, and we are glad to hear that intelligence has just been received that a satis-

Digitized by Google

factory concession has been granted by the Persian authorities. We may, therefore, look forward to early and energetic measures for the carrying out of this most desirable project.

NOTICES OF BOOKS.

THE Society of Arts, it will be remembered, arranged for the visit of a body of skilled artizans to the Paris Exhibition last year. This highly commendable step has brought forth fruits which are not confined to the workmen themselves, nor to the Society of Arts, but which are capable of influencing in some degree the whole range of arts and manufactures. The Society, ever on the alert to promote the object for which it was formed—the encouragement of arts, manufactures, and commerce—made it a condition that each visitor should report to the Society what he observed during his stay in Paris, with reference to the special industry in which he was engaged. The result would be, of course, in the first place, to lead each workman to carefully investigate the details of his business, as seen at Paris, and to fix any new feature in his mind. In the next place, the manufacturing world would be informed of matters of special interest to itself by men from among its best workers. That is, of course, assuming that the Society of Arts published the reports. They have done so, and in the volume before us* we have a series of practical reports of the greatest value to art and manufacture. The work is divided into two general parts, the first of which comprises reports by artizans from London, Sheffield, Coventry, Bradford, &c., the second being devoted exclusively to the reports from Birmingham artizans. There are eighty-two reports on the various branches of trade and manufacture, from plastering to watch-making, and all the reporters deal with their subjects in a sensible and practical manner. There is much instruction, with occasional amusement, to be obtained from the reports, which are readably written, although they are for the most part by men who have never attempted such a thing before.

Besides the artificers' reports, there are two special reports by Mr. R. Coningsby and Mr. R. Whiteing, on the condition and habits of the French working classes, which are well worthy of perusal by all. Some of the artizans appear to have gone to France slightly impressed with the idea which has of late been gaining ground in some men's minds, that England was being surpassed in details of workmanship by continental nations. This illusion was decidedly dispelled by careful examination, which proved that although France may have improved upon herself in some details of manufacture in which we formerly took the lead, we have also made good progress in departments in which we once owned her superiority. Mr. Whiteing sums the matter up very properly in his report when he says:—"If France has made progress in the coarser arts—if she now manufactures machines which enter the English markets and compete advantageously with our own—we have made an advance not less marked in all those manufactures in which formerly the taste and skill of the art workmen of France gave them undisputed sway. For every French steam engine consigned to a foreign port, where once only English machinery was in demand, a hundred bales of textile fabrics from the English looms are now sent to cities which once only opened their gates to the productions of French skill; and English art manufacture, unheard of but a few years since, is beginning to be a power in the world." As a whole, the reports reflect the highest credit on a body of workmen, and we trust they will be read and well studied by their fellow workmen, to whom they will prove highly interesting and instructive. To enable them to do this, we would suggest a reprint of the reports, classified according to trade or manufacture, and sold separately to workmen only, at the lowest possible price. This would thoroughly enable the Society of Arts to carry out the important principle of advancing the arts and manufactures.

Our lonely traveller, Captain Macgreggor, has made a third vacation trip over deep and shallow waters in a "Rob Roy"—not the "Rob Roy" canoe of the previous trips, but a new vessel, a yawl. Captain Macgreggor has exchanged the paddle for the sail and helm, and in a capitally-arranged and judiciously-fitted sailing boat, made the water his home for a good portion of last summer. The incidents of this voyage form the subject of an interesting book* written and graphically illustrated in Captain Macgreggor's now well-known happy style. The new "Rob Roy" is a yawl-rig, double skinned and full decked; she has an iron keel and kelson, and is divided into four water-tight compartments. Her internal arrangements for cooking, reading, writing, provisions, stores, and cargo, are a perfect wonder in their way, and must have cost the Captain some close thinking. However, they proved very satisfactory, and enabled our author thoroughly to enjoy himself alone on the ocean. The earlier part of the voyage, along the dangerous coast of France, was, fortunately, performed in fine weather. The "Rob Roy" then sailed inland and visited Paris, after which she crossed the Channel to Cowes and attended the regattas. The Medway and the Thames were visited on the homeward route, the whole journey being performed by the author without any companion, but with evident enjoyment and satisfaction. Captain Macgreggor does not write for the mere sake of writing, but he has a practical aim and end; he shows how men possessed of a reasonable amount of nerve and energy may recruit health and strength in a most enjoyable manner. Hence, his narrative is instructive as well as interesting. Nor does he write for personal profit: he has a far higher and far more praiseworthy object in view. His profits are to be given in prizes to the "Chichester," the "Indefatigable," and the "Havannah" training ships for boys. May the profits be in proportion to the merits of our author's work, and those of his proposition; so shall the work of our training ships be promoted and our naval interests appreciably advanced.

The name of Thomas Telford is a watch-word among engineers; he stands out boldly in the early days of the profession, the founder of a race of men who look back with pride upon his works. There are few who have not learned something of this great man's life from Mr. Smiles' lives of the engineers, and there are few who would not be glad to learn more. This Mr. Smiles has enabled them to do in a revised and enlarged edition of Telford's life,† to which he has prefixed an interesting account of the early roads and modes of travelling in Britain. In the course of his life, Telford constructed highways in North Wales and in the Scotch Highlands through previously inaccessible districts. Mr. Smiles tells us, that while the construction of the Highland roads was in progress, the late Robert Southey, poet laureate, visited the Highlands in company of his friend, the engineer. The poet left on record an interesting account of his visit in a manuscript, now in the possession of Mr. Robert Rawlinson, C.E., and from which extracts are made in the volume before us. It needs no pen of ours to commend Mr. Smiles' works. He has taken his place as the biographer of engineers, and he continues to maintain his position with increasing interest, as regards his readers and the profession to which he has thus attached himself.

The sewage question had its share of discussion during the past year. Meetings were held, speeches were made, papers were read, and pamphlets were written, until the question seemed farther off its solution than ever. A leading man in the matter, and an authority, too, is Mr. Baldwin Latham, C.E., who has had considerable experience in the great work of dealing with sewage. This gentleman has lately penned a very useful pamphlet,* explanatory of what has been done for effecting the purity of our rivers, and the mode of applying sewage in a liquid form to land. Lithographed drawings of the Croydon irrigation fields are given, the plan here being to lead the sewage into open tanks, where the solid matters are strained from the liquid portion. The liquid is then conveyed, partly by covered and partly by open channels, to the irrigation land, which is laid out on the pane and gutter system. The results of irrigation here are really surprising, and testify to two things—the value of the sewage and the judicious method of its utilization. We have also received a lecture on the sewage difficulty (Spon) which was delivered by Mr. Latham at Maidenhead, before the local board of health, in reply to Mr. Pearce's paper. Our author makes out a satisfactory case for sewage irrigation, and throws a considerable amount of light upon the subject. All who may be in doubt or difficulty about their sewage should read this lecture, which will show them the way out of their troubles most clearly. Very closely allied to the subject of Mr. Latham's pamphlet is that of storage reservoirs, the designing and construction of which has been ably treated by Mr. Arthur Jacob, in a paper read before the Society of Engineers, and now published in a separate form (Spon). As the paper was given in our pages at the time of reading, we need not refer to it here further than to state that the Society awarded Mr. Jacob a premium for it, which circumstance indicates its practical value. It is accompanied by several sheets of lithographed drawings, and will be found useful to all who may be engaged on irrigation work.

The most important contribution lately made to meteorological science is undoubtedly Mr. Strachan's pamphlet on the principles of weather forecasts.† The author sets forth the principles upon which weather forecasts and storm warnings appear to have been based, and he certainly explains them in an original manner. He does this, too, more methodically and with greater exactness than has hitherto been attempted. Working upon data, scientifically and mathematically he arrives at principles in a legitimate way. Not content with assertions and vague references to facts, he makes facts speak for themselves. The author is evidently master of the whole question, and we regret he did not enter somewhat more into its many details, for which he has shown himself fully capable. He shows that the late Admiral Fitzroy acted on scientific principles, and that others besides himself were acquainted with them. The subject is of the greatest interest and importance at the present moment; its bearings are very wide, and stretch away far more widely still into the unseen future. There can be no doubt but that men are at present groping in the dark, and all who can throw a light upon the subject of storm warnings and weather forecasts will be doing science and his country good service. Mr. Strachan has begun to do this, and one who can say what he has, can say more; let him therefore take heart and proceed. As for the pamphlet before us, we heartily commend it to the notice of all who

are interested in the science of weather wisdom, which is deeper and more exact than many dream, and to which Mr. Strachan has done good service. and will, we hope, do yet more.

We are glad to renew our acquaintance with Mr. Symons, in a very useful little book on the subject of rain.* The author's labours in this department of meteorological science are well known and appreciated; he has now added another proof of his zeal in the cause by the production of a popular account of rainfall investigations. Rightly apprehending that there are many who would like to learn the interpretation and practical use of the records of rain, Mr. Symons explains the method and results of rainfall measurement in the most simple terms. Being thoroughly at home in his subject, he will be found to interest those who otherwise might be disposed to turn their backs upon the subject. He has succeeded admirably in embodying all the important facts connected with rainfall, illustrating the instruments used in its measurements, and giving ample instructions to those who desire to observe for themselves. Mr. Symons gives an interesting diagram showing the fluctuations in the fall of rain from the year 1726 to 1865, as well as tabular results of recent investigations. The utility of rainfall observations is so well recognized that we need not here insist on that point. Let those who admit and wish to promote this utility, obtain Mr. Symons' book, and the few simple utensils necessary, and let him then advance the interests of science by making his own observations, and forwarding the results to Mr. Symons.

No one can complain that there are no opportunities offered for the general pursuit of meteorological observations. And we are glad to see it, for it is a testimony to the value of this science which hitherto has not been much cared for, but which now appears to be increasing in the public estimation. In furtherance of this science, we have under the simple title of "A Companion to the Weather Glass,"† a useful little annual which teaches the practical use of the barometer. The book is designed to record numerically and graphically the natural phenomena presented by the barometer, thermometer, rain gauge, clouds, wind, &c. In short, it will be found a very useful "companion," to meteorological observers, and will render the weather-wise still wiser.

The engineering annuals are to hand. They present no new feature, but are as useful as ever. "The Engineers' Pocket-book for 1868" (Lockwood) has become a necessary book of reference to the engineer, the architect, and the contractor. It affords the usual amount of correct and reliable information upon the varied points of professional pratice. Side by side with this book, of coune, we always see "The Builders' and Contractors' Price Book" (Lockwood), which Mr. Burnell now so ably edits. To complete the trio, we have "The Engineers' and Contractors' Office Sheet Almanack" (Lockwood), which, in addition to the usual calendar, contains a number of formulæ and useful tables, which are seen at a glance, and when done with are folded up in a compact form within a cover. "The Railway and Commercial Almanack," edited by Mr. W. P. Smith (Simpkin), will be found very useful to bankers, mining men, insurance companies and others engaged in commercial pursuits. It contains some excellent articles on the various industrial productions, and a variety of information which will prove useful to the merchant, the manufacturer, and the general public, to whom we commend it.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

A NEW ANILINE GREEN—ACTION OF WATER ON LEAD, AND ITS PREVENTION—RECOGNITION OF NITRATE OF SODA IN NITRATE OF POTASH MADE BY THE CONVERSION OF NITRATE OF SODA.

MANY attempts have been made to produce an aniline green dye, but they have been rewarded with but imperfect success. The blue colour which is produced when most aniline salts are treated with an oxidizing agent becomes green under the influence of an acid. A green colour is also developed by the action of chlorate of potash on a salt of aniline. This is Dr. Calvert's emeraldine. None of these greens, however, can be used as dyes. But a green dye has been patented by Keisser, of Lyons, which is applied to silk as easily as the red and blue aniline colours. It is a compound of picric acid with triethylrosaniline, the base of Hofmann's blue. The methyl, amyl, and phenyl compounds also lend themselves to the reaction, but the ethyl compound answers best. To prepare the base, Keisser dissolves one part of Hofmann's blue in three parts of alcohol of 90 per cent. strength, and adds one part of iodide of ethyl. This mixture he heats for half an hour in a close vessel, then adds one or two parts of caustic potash or soda, and heats again for three or four hours. The mass resulting is washed with boiling water, the washings being saved for the recovery of the iodine. A blackish doughy residue remains, which to prepare the picrate must be heated with 500 or 600 times its weight of water, in which it perfectly dissolves at 212deg. The solution must be filtered hot, and then a hot aqueous solution of picric acid is stirred in until the fluid acquires a distinct yellowish-green colour. It is now allowed to stand for twenty-four hours, when the picrate of triethylrosaniline will have been deposited. It has only to be separated by filtration or decantation and dried, and is then ready for commerce. For dyeing it has only to be dissolved in alcohol, the solution poured into the bath, proceeding exactly as with the other aniline dyes. The colour given is said to be a beautiful yellowish green.

Distilled water, as is well known, acts on lead and dissolves a small quantity of that metal. This is usually ascribed to the presence of air dissolved in the water, but Böttger states that it is due to the presence of carbonate of ammonia. Distilled water after active ebullition will not attack the lead until after a considerable exposure, when a reabsorption of ammonia and carbonic acid, which are always present in the air, may be supposed to have taken place. When water is examined for its action on lead, Böttger points out that pure lead must be used, for the presence of a small amount of tin will prevent any action from taking place. This fact suggests the employment of lead alloyed with a small amount of tin for water piping and cisterns.

Saltpetre, or nitrate of potash, is now made in large quantities by the double decomposition of chloride of potassium and nitrate of soda—Chili saltpetre, as it is called. In practice it is found extremely difficult to tell when the whole of the nitrate of soda has been converted into the potash salt, and manufacturers are apt to send out a saltpetre which is unfit for the manufacture of gunpowder. Most gunpowder makers, in fact, decline to use saltpetre made from nitrate of soda, although it has been said in a report on the subject to the Italian Government not to be objectionable. The presence of any nitrate of soda in a saltpetre is easily detected by its deliquescent property. Nitrate of potash remains dry in the air, but the presence of only one-fourth or one-eighth per cent. of nitrate of soda in saltpetre is shown by the fine powder becoming moist on exposure, and increasing in weight. Nöllner states that one washing will completely remove all nitrate of soda from such deliquesced saltpetre. He has determined, with no particular object, that we can see, the rate at which nitrate of soda attracts moisture:—One gramme exposed to the air in a cellar after 5 hours weighed 1·2grm.; after 24 hours, 1·5 grm.; after 48 hours, 1·87grm.; and after 72 hours, 2·387grms. The presence of nitrate of soda in a saltpetre is certainly shown by the deliquescent property communicated; and some idea of the amount can no doubt be gained from the weight of the water attracted; but Nöllner is careful to add that an accurate determination can only be made by estimating the amount of potash and nitric acid, and calculating the soda by difference as usual.

REMARKABLE PHENOMENON AT RANGOON.

BY DR. C. COLLINGWOOD, F.L.S.*

I ACCIDENTALLY heard mention by an eye-witness (a lady residing at Hong Kong) of a circumstance which struck me as so remarkable and interesting that I collected the particulars with care, allowing the narrator to tell her own story, and filling up important particulars by putting questions as little as possible calculated either to lead or mislead.

It was in the year 1846 that she was on board her husband's ship the "Manook" in the Rangoon River, and was walking up and down the poop, in company with the chief mate and a child four years old, the poop awning being at the time spread overhead. It was about half-past 7 in the evening, and then quite dark, when suddenly, without any warning, a tremendous sheet of light appeared to rush across the bows of the vessel in a horizontal direction. The light was not like lightning, but appeared to pass swiftly along, and had the aspect of a red thick flame, occupying the whole space left visible between the awning and the ship. The suddenness and terrific nature of the glare was such that she fell down upon the deck, believing, as she expresses it, that the world had come to an end, while the child screamed aloud with terror.

As this frightful luminous appearance rushed by the ship a considerable accession of heat was felt by both the adult persons, and a strong sulphurous smell also accompanied it, though how long this feature lasted cannot now be stated with any certainty. But the phenomenon was unaccompanied by any sound, and sped noiselessly on; nor could they see where it went or what finally became of it. The whole affair lasted but some seconds, the light having dashed past them with a speed only inferior to lightning. The captain of the ship, and Captain Brown, postmaster and only European resident at the time, were in the house of the latter, situated but a short distance from the shore and from the ship. They both averred that they felt a sudden and remarkable heat, although they saw no light; and when told of the circumstance afterwards, on comparing notes as to the time, they immediately exclaimed words to this effect, "Then that explains the sudden and unaccountable warmth we felt at that time." It is worthy of remark that my informant spontaneously stated that, as well as she could recollect from collateral circumstances, this must have occurred some time during the month of November.

The two gentlemen on shore are both dead; but the mate is believed to be still living. It was often a matter of wonder to them that an occurrence which to them appeared so extraordinary was never publicly noticed; but it seems they were the only Europeans who observed it, as I learn that, besides the natives of the place, the only other residents at that time were Armenians. The whole account which I have been able to gather of this phenomenon so closely agrees with the description given of that class of meteors known as silent fireballs or bolides, that I feel convinced that my informant must have witnessed one of these bodies in terrific proximity; and as I am not aware that any one has ever recorded such an experience, I have thought it worth while to draw up this *proces verbal*, to which my informant has attached her sanction. When at Dundee I was much struck by Mr. A. Herschel's concluding experiment, which represented a silent bolide, and considerably startled the audience by its noiseless flash across the back of the hall. The gliding light and the accompanying heat forcibly recalled to my recollection the particulars I had gleaned of the Rangoon phenomenon.

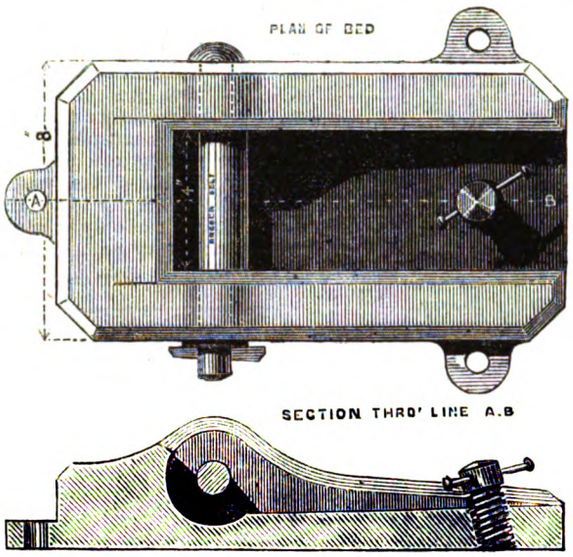
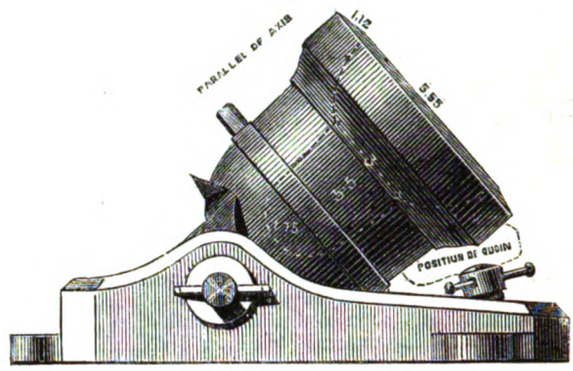
MORTARS FOR MOUNTAIN WARFARE.

By Captain G. R. Mann, R.E.





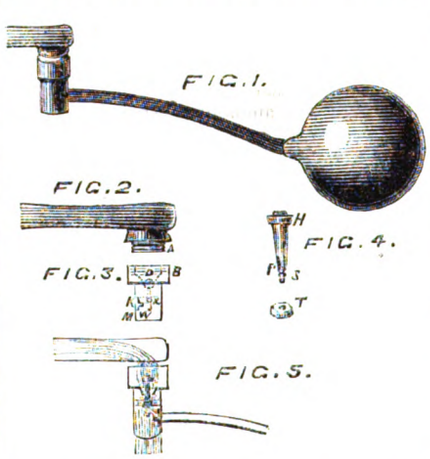
MOUNTAIN MORTARS.

AFTER all has been done to reduce the weight of mountain mortars to a minimum, it remains a fact that they are not portable in the highest degree, and it is not to be denied that in the endeavour to secure such portability as they possess much of their efficiency has been sacrificed. We believe that as a consequence of the existing prejudice against mortars a very valuable weapon has not been supplied to our Abyssinian troops, and, as none of the essentially military papers have called attention to the subject, we do so. About twenty-four years ago we carried on a war against certain of the aboriginal New Zealand tribes, and a very troublesome, and, in its way, expensive little war it proved to be. At that time we had no rifled mountain guns, but we had little howitzers, intended to answer much the same purpose, and probably not much less efficient. These howitzers, however, proved to be next to useless. The natives entrenched themselves within pahs, from whence they could not be dislodged, and into which our troops could not get without great loss of life. The pah consisted of spaces enclosed by walls made of piles driven in two rows about 4ft. asunder, the space between being filled with clay after the manner of a coffer-dam. The little howitzers in some cases could not be brought up to act against these pahs at all, and in others they could not breach the walls. "Toney Heckey," a native chief, constructed one of these pahs on the top of a hill, from which he could not be dislodged. In this emergency, Capt. G. R. Mann, R.E., proceeded to Sydney, and from his designs twelve little mortars, as illustrated in the accompanying engraving, were made by Mr. Russell, of Sydney.

Our engraving, for which, with this description, we are indebted to the "Engineer," prepared from the original tracing made twenty-four years ago, illustrates their construction so clearly that no special description is necessary. The cast iron base weighed but 28lb., and was fixed to a piece of two-inch plank 24 by 16. The mortar, of gun metal, weighed only 65lb. and was, of course, still more portable. The charge consisted of 8oz. of powder and a common 5in. shell. It may be thought that as there was no length of chase, only half the shell being contained in the mortar, the range would have been very small. In point of fact, however, the range was 550 yards, quite sufficient for the required purpose. These little mortars were carriad up by a few men within a few hundred feet of the pah to be attacked, and pitched their shells with ease into the very heart of the camp. They proved perfectly effectual, and infinitely more useful than the small guns, not only in attacking pahs, but in dislodging the enemy from jungle, as they could be put down at a moment's notice, and used while troops were on the march. They certainly exceed in power any other weapon of equal weight, for a 5in. shell, weighing some 12lb. or 14lb., and containing a heavy bursting charge, is no contemptible foe. The remarkable range of these little mortars is an excellent illustration of Lynall Thomas' theory of the percussive action of exploding gunpowder, and it is possible that with gun cotton the range would be still greater. Judging by the good service they have done, we cannot resist the conclusion that a few such mortars would prove a useful addition to our Abyssinian armaments.

WATER SUPPLY REGULATOR.

AN apparatus for regulating the supply of water, or any other fluid, has been patented by Messrs. Bland, of London-fields, Hackney, in conjunction with Mr. Brevetor. The apparatus is so constructed as to be when fixed without any opening whatever, except the one expressly intended for the outflow of the liquid, whereby the possibility of leakage is reduced to a minimum. The valve is made wholly of metal, without needing the aid of any other material, such as leather or india-rubber. By the construction of the apparatus the pressure of the liquid in the supply pipe aids in perfectly closing the valve, and therefore a proportionately much smaller lever and ball are required than usual. The connection of the spindle in the valve with the lever and ball is made beneath or beyond the point of outflow. It can be removed or replaced without trouble or necessity for plumbers' joints, rather a bad feature, we think, for the inventors, who are plumbers by trade. The construction or mode of action is such as to occasion the



least possibility and liability to get out of order by grit or sediment, as the flow of the liquid acts as a continuous lubricator, and washes away any obstruction that might be present.

In our engraving, fig. 1 represents the apparatus complete. Fig. 2 represents the arm Z to be fixed by a plumber's joint to the supply pipe, and furnished with a male screw A. Fig. 3 represents the valve case K furnished with a female screw B at the top, intended to receive A. D is the opening for the outflow of the water; the case has a bar or bridge X with an aperture W to guide the spindle, and also an opening; M is the side through which the lever or stem of the ball enters. Fig. 4 shows the spindle H with the shoulders V and a thread P. The nut T at at the bottom is to secure the lever or stress of the ball. Fig. 5 represents the action of the apparatus when open.

INSTITUTION OF CIVIL ENGINEERS.

AT the first meeting of the present session of the members of the Institute of Civil Engineers, held on Tuesday evening last, Mr Charles Hutton Gregory took the chair for the first time since his election as president, and delivered an address.

He remarked, that when the Institution was founded, fifty years ago, on the 2nd of January, 1818, the members were six in number. Two years later, Thomas Telford became the first president; and the Royal Charter of Incorporation was obtained on the 3rd of June, 1828, by which the Institution was firmly established as the recognized representative body of the engineering profession in the United Kingdom. There were now on the register 1,472 members of all classes, besides 95 students. The present condition and prospects of the profession were briefly alluded to, and it was observed, that the railway system of this country had, by economy of transport alone, been productive of direct saving to the public of 15 per cent. on the capital expended.

A reference to the past records of the Institution had brought to light one document which, Mr. Gregory believed, would be interesting to every engineer. This was a description of the nature and objects of civi engineering, by Thomas Tredgold, Hon. M. Inst. C.E., some of the expressions in which had been embodied in the charter; but as it had never yet been printed in a complete form, the president now gave it unabridged. After defining the duties required of the civil engineer, Mr. Tredgold concluded by saying that "the real exten to which civil engineering may be applied is limited only by the progress of science; its scope and utility will be increased with every discovery in philosophy, and its resources with every invention in mechanical or chemical art, since its bounds are unlimited, and equally so must be the researches of its professors." It could hardly, however, have been foreseen, that the attention of the civil engineer would have been directed to aid in constructions for defence from hostile attack, and even to the improvement of weapons of war. But as, more than two thousand years ago, Archimedes, distinguished first in mathematical science, after carrying out the great work of the embankment of the Nile, devoted the last efforts of his genius to engineering appliances for the defence of Syracuse against Marcellus, so now, less directly and less prominently, but with marked success, the combined labours of modern engineers had been applied to the purposes of national defence, and to this subject the president stated he proposed more particularly to allude.

The application of machinery to the manufacture of rotating fire-arms was first brought under the notice of the Institution, in the year 1851, by Colonel Samuel Colt, of the United States. In 1853, Mr. John Anderson, M.I.C.E., the engineer to the Board of Ordnance, suggested the construction and equipment of a Government manufactory, in which, by the use of complete machinery, all

Digitized by Google

the processes for the production of small arms should be carried on successively to completion. This issued, after inquiry before a Select Committee of the House of Commons, in the establishment of the Small Arms Factory at Enfield, which was set to work in January, 1857, under the direction of Colonel Manley Dixon, R.A., the present superintendent, up to December 26, 1867, the total number of new arms made at Enfield was 616,828; while the number converted to breech-loaders on Snider's plan to the same date was 175,550. The long Enfield rifle consisted of 53 parts, and passed through about 740 processes of manufacture. The machines used were to a great extent varieties of copying machines, where a standard model was reproduced by a revolving cutter, in wood or metal, as might be required. The different pieces, as produced, were checked with templates and gauges, and, finally, the stock, lock, barrel, bands, bayonet, plates, screws, &c., found their way in numbers to an "assembler," who, furnished only with a screw-driver and a chisel, took up the pieces indiscriminately and fitted them together; and so entirely interchangeable were the parts found to be, that a payment of 3·29 pence for each rifle put together, gave the workman wages of about fifty shillings a week. It was stated that the average cost of the long Enfield rifles, made at the Government factory, including an allowance of 5 per cent. on the cost of buildings and machinery, for depreciation, had been about £2 each, and of the short Enfields complete £2 14s. each. The cost of converting to the Snider breech-loader, including £10,000 for the alteration of old machines and the supply of new ones, as well as 5 per cent. for depreciation on buildings and plant, was said to be about 16s. 3d. per arm. It was stated that, with the present machinery, the Enfield factory was capable of turning out about 130,000 new arms annually. It had been estimated, that the improvement arising from the accurate work produced by good machinery, coupled with better ammunition, had resulted in reducing by 50 per cent. the mean deviation in rifle shooting; while elements of precision and economy had been introduced, by the perfect convertibility of all the parts of small arms, which were previously almost entirely neglected by the English gun-making trade.

Mr. Gregory next referred to the production of heavy armour plates and large guns, with their consequent results. He said that while, prior to the Crimean war, suggestions had been made and partial experiments had been tried, with a view to the use of iron for defensive purposes, the credit of the first great trial of a practical nature was due to the Emperor of the French, who built three floating batteries cased with thick iron plates, which were engaged in the attack of the allies on Kinburn, on October 17th, 1855. From that date public attention was drawn more closely to the protection of ships of war by armour plating, and various experiments were made in this country. It soon, however, became apparent, that the subject of the use of iron for this novel purpose was so complicated by considerations of a purely technical character, that it was determined to submit the whole matter to the investigation of a mixed Special Committee, which was appointed in January, 1861. This Committee continued in existence for between three and four years, and their investigations and experiments, which were of great value, formed the best history of the application of engineering science and practice to this particular subject; and it was to be regretted that the four large volumes, containing a full record of all their proceedings, had not been published. The president was, however, enabled to give a brief epitome of the results that had been early arrived at, on points which had previously been uncertain. For example, out of many varieties of material, it was found that the best for resisting shot was wrought iron; that this should be of the softest and toughest quality, any hardness or steely character being prejudicial; that *cæteris paribus*, the resisting power, up to a certain limit, varied nearly as the square of the thickness; that corrugations, bosses, or irregularities of surface were disadvantageous, plain surfaces being best; and that the plates should be as large, and with as few joints, as possible. Various constructions of iron defences, both for ships and for land fortifications, were examined and tested on a thoroughly practical scale. The experience thus obtained had reference not only to the strength and capability of the material generally to resist shot from given guns, but also as to the modes of fastening, the effect of various kinds of backing, and the general principles which should guide iron defensive construction. But perhaps the most valuable result, in an engineering point of view, was the improvement effected in the production of iron in large masses. When the Committee began their labours, the manufacture of armour plates had only been attempted by one or two makers, and even in their hands it was little more than tentative. After three or four years' experience, many makers had come into the field, the general average of quality was much improved and more certain, and plates of 5 inches and 5½ inches in thickness could be produced with their full resisting power. During the last few years, the size and thickness of iron plates had greatly increased; and thoroughly sound and uniform plates of large size, 10 inches in thickness, might now be regarded as an accomplished fact. In the middle of 1864 the Iron Plate Committee was dissolved, a step which Mr. Gregory considered to have been injudicious; as the comparative question between guns and iron defences was at that time in a high degree progressive, and, if improvement was to go on, the technical treatment of the subject must still be necessary. Recent circumstances had led to the temporary re-appointment of a Government Committee to consider the question of the application of iron plates to land forts; and it was to be hoped that their labours might not be prematurely checked, nor until safe data were deduced from actual tests.

Concurrently with the production of iron plates, for purposes of protection, had been the increase in the size and destructive power of guns. For many years before the Crimean war, brass and iron guns had been made with very little change of form, although there were in existence compound or built-up guns of an early date. When public opinion was drawn to the application of mechanical improvements to the production of guns of great size and strength, many designs were brought forward, and the large wrought-iron gun of Mr. Horsfall, and the monster mortar of Mr. Mallet, M.I.C.E., were cited as examples. But the battle of the guns was chiefly between Sir W. G. Armstrong, C.B., M.I.C.E., and Mr. Whitworth, M.I.C.E. As far as the construction of the guns was then concerned, the leading points of difference were, that while the Armstrong gun was built up of several rings or tubes of coiled wrought iron shrunk over one another, and over a steel lining, with small grooves to take a soft-coated projectile, the Whitworth gun was built of tubes of mild steel, forced with a taper over one another, and over a steel lining, the bore being polygonal, with a mechanically-fitting projectile. The details of both systems were subsequently more or less changed, and in January, 1863, a committee was appointed to make full experiments and to investigate, with two calibres, viz., 12-pounders and 70-pounders, the comparative merits in construction, endurance, range, and accuracy, and, in fact, in all the qualities which a gun should possess. The information so collected showed, in both systems, results as to structural strength and efficacy, and accuracy of fire, which had not been previously attained; and while it was not in all respects conclusive as to the comparative merits of the guns, it brought out more prominently than ever the perfection to which artillery might be brought by the application of engineering skill. Irrespective of breech-loading, which had been abandoned for heavy guns in this country, and of rifling, in which the original mode had been to a great extent superseded by larger grooves cut in the chase of the gun to guide soft metal studs fixed on a hard metal projectile, the gun now generally manufactured for the service had undergone considerable structural changes. The most material were, the diminution of the number of parts, and the substitution of outer coils of fibrous Staffordshire iron, for coils of the best Yorkshire iron, tough steel being still maintained for the lining as best resisting surface wear. The pattern at present in use for all guns consisted of only four pieces:—1, the steel barrel or lining; 2, a coiled tube over the barrel, extending from the muzzle nearly to the trunnions; 3, the breech coil, of three coils in alternate directions, welded together, with a trunnion piece welded on, the whole being shrunk on over the breech of the barrel, and lapping over the front coil; and 4, the cascable. It was considered by the authorities, that guns of this pattern were less liable to injury by accident, and less dependent upon perfection in manufacture, and that practically an equal amount of strength was obtained; while it was held that a fibrous iron was to be preferred as more workable, and as giving out its greatest strain over a greater distance than the best Yorkshire iron, which, while stronger, statically considered, did not yield so far before fracture. It was said that this change had diminished the cost of production by 35 or 40 per cent. Prior to the mechanical improvements which had led up to the present rifled guns, the greatest distance to which a projectile was ever thrown from a small-bore gun was not much over 6,000 yards, and the limit of bombarding range, at high elevations, with the 13-inch mortar, was 4,500 yards. With the modern ordnance, projectiles had been thrown, with greater precision, to a range exceeding 10,000 yards; and the guns of the service made good practice at 6,600 yards; indeed, better practice than was formerly attainable at 3,000 yards. At 1,000 yards the rifled gun was eleven times, and at 2,000 yards, thirteen times more accurate than the smooth-bore. But these improvements would be of little avail in time of need, until smooth-bores were much more largely replaced by rifled guns; as, for all practical purposes, many of our defences, both at home and abroad, were, at present, almost unarmed.

While such important changes had been effected in ordnance, the advance recently made in naval construction was alike remarkable, and would have been equally impossible without the resources of modern engineering. Without attempting to trace the progress from wooden to iron ships, or all the steps by which naval architects had passed, from the earliest to the most recent types of armour-clad ships, Mr. Gregory illustrated the general results by some comparisons between the structures of the "Warrior" and the "Hercules," as ships of 1860 and of the present period respectively. The arrangement now adopted for the broadside ships of the Royal Navy, provided a protected battery amidships, shut in by armour-plated bulkheads, and a belt of armour for the whole length in the neighbourhood of the water line. By these means, in addition to the battery and the whole water line, protection was given to the engines and boilers, and to the rudder-head and steering apparatus. In the "Hercules," the sides of the ship were recessed before and abaft the central battery, so that by means of embrasures in the armour-plated bulkheads, the foremost and aftermost gun on each side could be traversed on a turn-table, and be fired at an angle of 15deg. with the line of the keel, while that line was commanded by the guns in the bow and stern batteries. The "Hercules" was 8in. wider in the beam than the "Warrior," but 55ft. shorter, and of 883 tons less burthen. She would carry a smaller number of heavier guns, and possessed the elements of greater power, both for offence and defence; but in the former quality she was, perhaps, inferior in some respects to a type of ship now on the stocks. The Royal Navy, at the present time, comprised thirty-one iron-clad ships, and eight more were building, four of the existing ships are being furnished with turrets, which were to be supplied to two of the new ones. Admitting that this number represented a formidable force, and that in structural qualities the vessels recently built were superior to those of other countries, it must be remembered that many were of doubtful strength, and that the sum devoted to the construction of new iron-clad ships for the current year, was less than one-twelfth of the vote for the navy, and was barely sufficient to build three iron-clad frigates—a fact meriting the gravest consideration.

The next point touched upon related to the important bearing of railways in modern warfare. They were acknowledged to have been of great use in the movement and concentration of troops during the war in Lombardy, in 1859. In the German War of 1866, the Prussian Government organized a special corps, consisting of workmen and railway servants to act under the direction of engineers and traffic officers, to repair damages effected by a retreating enemy, to work lines occupied by the army, and in case of retreat, to destroy lines in the rear. Mr. Hozier, in his admirable account of the Seven Weeks' War, though conceding the value of improved roads and railways in shortening the duration of campaigns, especially in facilitating the transport of provisions, stores, and a siege train, and in relieving soldiers of heavy loads; yet he considered that the power of railways for the transport of troops had been over-estimated. Mr. Gregory's opinion seemed to be at variance with these views; and reference was made to the number of volunteers transported by railway, on special occasions, within a given time, as not being consistent with the conclusions of Mr. Hozier. Again, in the American Civil War, railways and steamboats were found to be of inestimable advantage, of which several illustrations were given.

MACHINE FOR BORING GUN BARRELS.

By Mr. Thomas Greenwood, of Leeds.

FIG. 3.

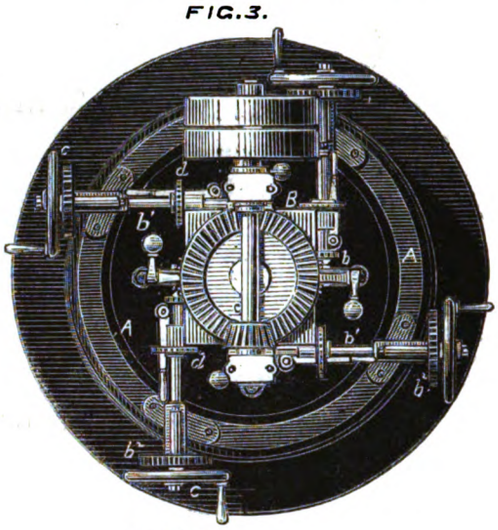

FIG. 1.

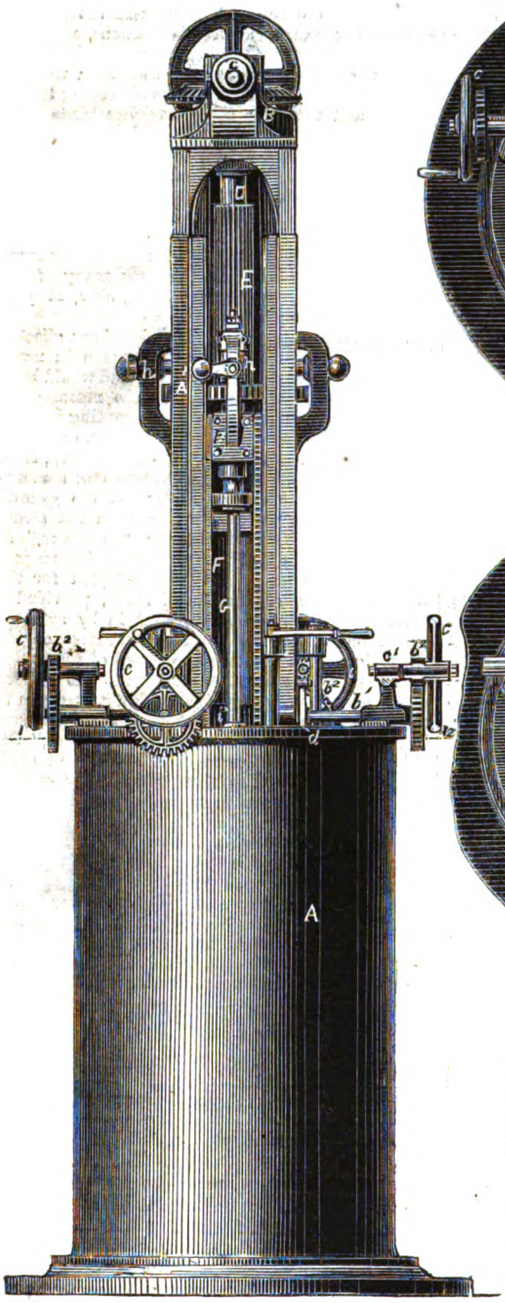

FIG. 2.

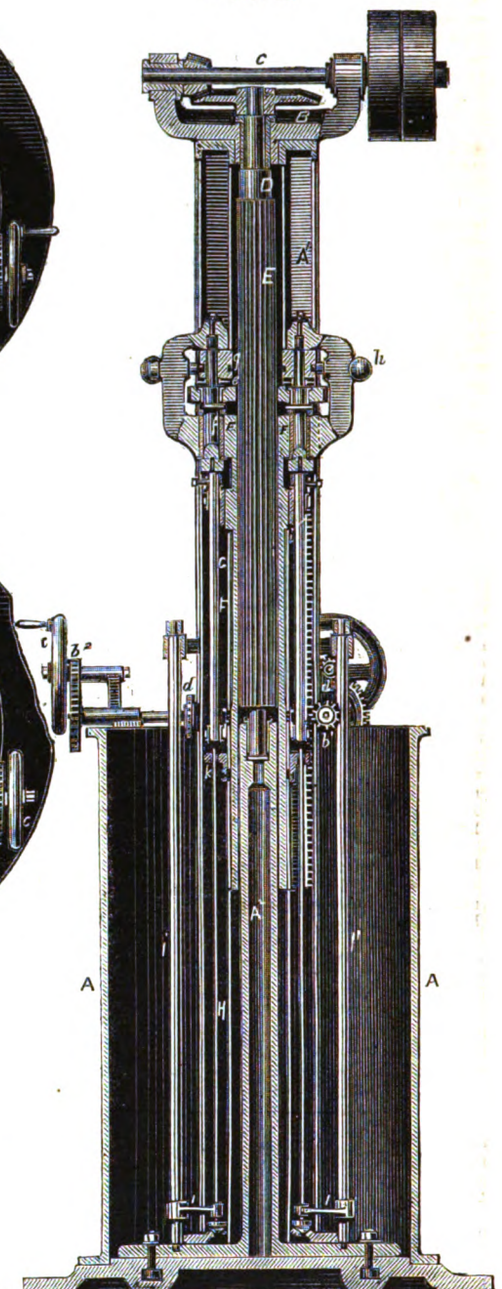

FIG. 4.

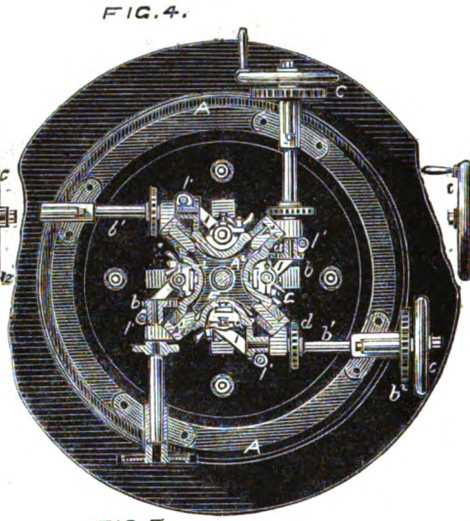

FIG. 5.

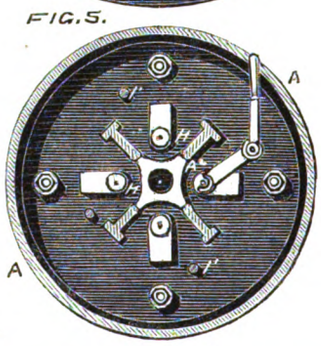


The railway system of this country was believed to be one of the greatest elements of strength for national defence; and it was mentioned that the confidential reports to the Government, by the officers of the "Engineer and Railway Volunteer Staff Corps," commanded by Mr. Bidder, Past President I.C.E., showed that the completeness and the resources of the railway system would enable the whole regular and irregular army to be moved upon any required lines of defence within a few days.

As a *resume*, Mr. Gregory submitted, that while it was advisable to maintain the efficiency of the Government establishments, yet that it would be a mistake to extend them so far as to cripple individual enterprise. In the next place he referred to the comparatively unprotected state of the Thames, the Mersey, the Clyde, the Tyne, and other rivers leading to rich towns, docks, and shipping; and he suggested the inquiry, whether if forts were thought to be desirable at such places, they might not be of small size, and capable simply of offering resistance to a sudden attack. And in regard to the navy, he thought the time had now arrived when the type of ship best suited for coast defence should be settled. The instinctive feelings of every Englishman called for the establishment and maintenance of a navy sufficiently strong, not only to defend our coasts, but also our colonies and our commerce; and if the Government would at once respond to that call, comfort would be brought to thousands at the present time suffering most grievous want.

In conclusion, the President expressed the earnest hope, that the future of the Institution of Civil Engineers might be as useful and as prosperous as its first fifty years had been; and that it would continue to supply men of character and intellect equal to every occasion, and who would join in the defence of their country, by contributing to her moral and material greatness, leaving England's future with confidence to the great source of all power and all intelligence.

MACHINE FOR BORING GUN BARRELS.

GREAT delay has hitherto been occasioned in clearing out the chips formed by the drill in boring solid metal, and defective drilling has often resulted from the accumulation of the borings. In order to avoid these inconveniences, and to insure perfect lubrication of the drills, Mr. Thomas Greenwood, of the firm of Greenwood and Batley, machinists, of Leeds, has contrived the arrangement of drilling machinery shown in the accompanying engraving. Here the work to be drilled is mounted vertically above a tank containing lubricating material, and bored upwards from its lower end by fixed drills mounted in the tank. Fig. 1 of our engraving shows in side elevation the improved drilling machinery arranged for boring gun barrels; fig. 2 is a central vertical section of the same; fig. 3 is a plan view; fig. 4 is a sectional plan taken in the line 1 2 of fig. 1; and fig. 5 is a plan partly in section of the tank and its fittings.

A is a cylindrical tank, to the bottom of which is bolted a central standard cast with a broad flange or base plate; this standard is composed of four flat-sided vertical members A^1 disposed radially around a short pillar A^2 and united together at top, as shown at fig. 1. On the top of the standards is fixed a casting B which forms the bearing for a driving shaft C; this shaft is fitted with loose and fast belt pulleys, and also a bevil pinion which gears into a bevil wheel keyed on to a vertical spindle D. The foot of this spindle is stepped into the top of the pillar A, which also carries a bearing for it to run in, and the upper end of the spindle is fitted with a bearing. Carried by the top of the standard keyed to the spindle D is an elongated spur pinion E into the

Digitized by Google

teeth of which gear spur pinions *e* for the purpose we shall presently explain. F F are four slides fitted to the standard, as seen best at fig. 4, and capable of sliding up and down it independently in guides provided for them. These slides F each carry a vertical spindle *f* on which the pinions *e* are loosely mounted. Each spindle is provided with a clutch *g* which slides on a feather on the spindle, and engages with the boss of the pinion *e* when the rotary motion of the pinion is required to be communicated to the spindle. An eccentric stud projecting from a short rock shaft *h* and operated by a handle enters an annular groove in the clutch, and thus lifts it or depresses it as required. These spindles *f* are intended to rotate the barrels submitted to the action of the drills, and for this purpose they are fitted at their lower end with an eccentric stud, which, when the spindle is rotating, bears against a projection from the barrel and drives it round under the action of the drill.

The barrels to be drilled are shown at G; they are dropped into and steadied by bearings *i* i^* carried by the slides F, and by means of rings clamped to their upper ends they are suspended from the upper bearings *i*. The bearings *i* i^* are carried by their several slides F; the upper bearings are fixtures, but the lower bearings i^* are adjustable in guides to which they are clamped to suit different lengths of work. These guides are formed at the lower end of the slides F, and in them are also fixed adjustable bearings *k* for steadying the cutting edge of the drills H which stand up from the bottom of the tanks. These drills are stationary and they rest upon fixed coned seats, being provided with coned heads to rest in those seats. This arrangement allows of the drills being readily removed for grinding, or of being replaced by others to suit a different kind of work. The work is generally allowed to descend by its own weight and to slide over the drill until the slide which carries it is arrested by a stop, but in order to raise the work the provision shown best at fig. 1 is made. This consists of a vertical rack *a* cast on the slide F, into which gears a spur pinion *b* mounted on a short spindle b_1, which carries at its outer end a second spur pinion b_2. In gear with this is a spur pinion keyed to the boss of a hand-wheel *c*, which is carried by a stud axle c_1 supported on a bracket attached to the tank A. When, therefore, it is required to lift the work clear of the drill, it is only necessary to turn the hand-wheel *c* and the pinion *b* will raise the slide F and the work with it. To retain the slide in the elevated position a ratchet wheel *d* and pawl are provided, and to prevent the drill rising out of the tank with the work a forked arm I embraces the drill and offers an obstruction to the coned head of the drill passing upwards. This forked arm is keyed to a rock shaft I_1, which is turned by a handle (see fig. 5) to disengage the arm from the drill when the drill is required to be moved.

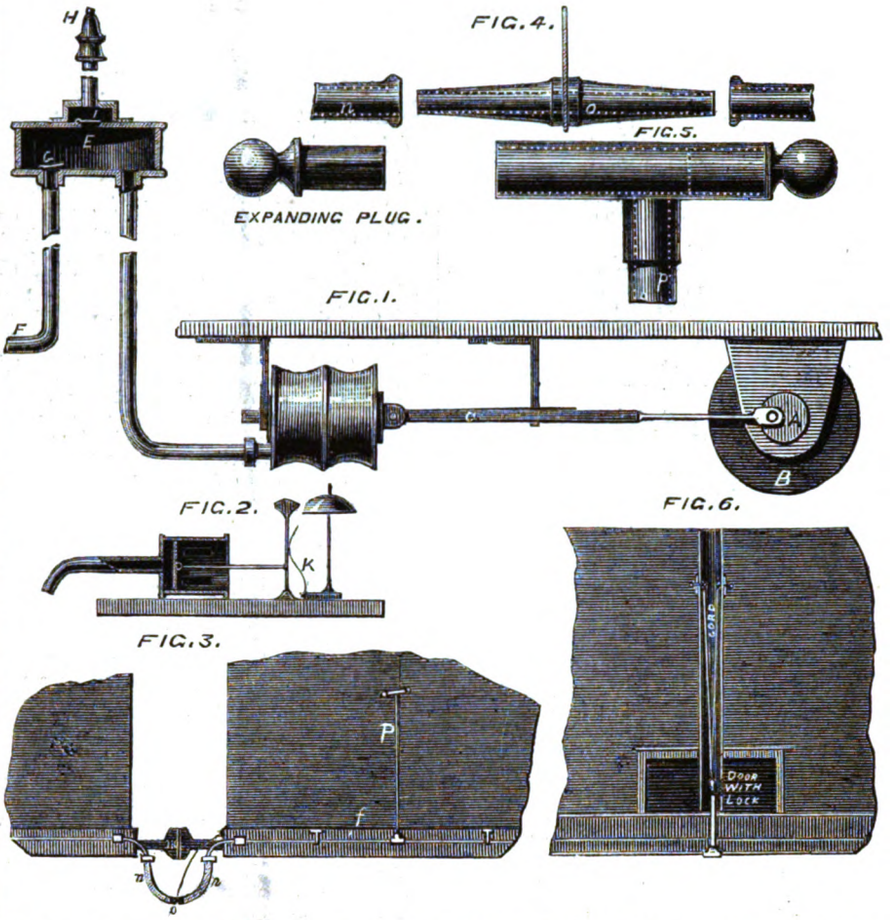
Mr. Greenwood proposes to charge the tank with water or other lubricant, keeping its level above the cutting edge of the drills, and the work will therefore be lowered down into the lubricant as the operation proceeds. When boring gun barrels or other light work, three, four, or more slides or carriers for receiving the work are arranged around the central standard. The carriers being capable of sliding in the vertical guides descend as the boring proceeds, or a self-acting motion may be applied to regulate the descent of the carriers when the machine is adapted for heavy work. Rotary motion being given to the central elongated pinion E, the pinions around and gearing into it will be driven, and they will thus rotate the work suspended below their respective spindles As, therefore, the work is fed to the drills the steady boring of the barrels will be insured. This operation may be continued without interruption until the boring is completed, as the chips or borings will fall by their own gravity, while the lubricant will have constant access to the drill. Of course this mechanism is modified to suit different kinds of work, but in all cases the work pendant in the lubricant will as the operation proceeds discharge the chips without the aid of the attendant, and thus render the boring operation continuous instead of intermittent as hitherto when solid metal has been bored.

PNEUMATIC APPARATUS FOR SIGNALLING ON RAILWAY TRAINS.

THE question of communication between guards and passengers of trains in motion attracted considerable attention last year, and is likely to do so again. Various plans of effecting the desired object are now under trial, and others continue to be proposed. Among the most recent and practical which have come under our notice, is that recently patented by Mr. Latimer Clark, the well-known telegraphic engineer, of No. 5, Westminster Chambers, Westminster. Mr. Clark's invention consists in the application of a pneumatic tube running the whole length of the train, with means for making connection between the carriages and the break vans when coupled together. A pump or bellows is fixed on the engine, and every guard's van, which is kept in constant action by the motion of the train, and continually exhausts the air from

PNEUMATIC APPARATUS FOR SIGNALLING IN RAILWAY TRAINS.

By Mr. Latimer Crark, C.E.



this pipe, all the bellows acting on the pipes simultaneously. Under ordinary circumstances, the pipe being closed, no air can be ejected by the bellows, and no effect will be produced in the guard's van or engine, but if an opening be intentionally made into any part of the pipe by the passengers or guards, or by the accidental separation of the train into two parts, the air will be freely admitted into the pipe, and all the bellows will come into action, and will begin to eject air violently. This air is ejected through a whistle, and by the noise it occasions it immediately attracts the attention of all the guards in the train, and also that of the engine driver. Flexible tubes of vulcanized india-rubber with spigot and faucet joints are employed for making the connections between the carriages.

In the accompanying engraving, fig. 1, *a* is an eccentric or crank fixed on the axis of a wheel *b*, which is driven by a strap passing round the axis of one of the wheels of the guard's van, and therefore revolves whenever the train is in motion; *c* is a rod working in guides, to which is attached the bellows *d*. A pipe leading from the bellows passes up into the guard's van, where it is in free communication with an air chamber *e e*; this air chamber is connected with the pneumatic pipe *f*, which runs the whole length of the train, and which communicates with the similar chambers and bellows on the engine and on the other vans. The pipe *f* where it enters this chamber is provided with a valve *g*, which freely permits the air to enter, but prevents its exit. The whistle *h* is also provided with a valve *i*, which allows the air to pass out from the chamber *e* through the whistle, but prevents its entry. As soon as the train is set in motion all the bellows commence to work, and at each stroke they exhaust a portion of air from the respective chambers *e e*, and and the pneumatic pipe *f*, and eject it out again through the valves *i* and whistles *h*, causing them all to sound. After a very few strokes, however, they have between them exhausted as much air from the main pipe as their construction permits, and have created a partial vacuum, and since no more air can enter at any part of the apparatus, the whistles necessarily cease to act, and become silent, and they continue so, however long the train may be in motion.

If, now, the passengers wish to make a signal to the guard and engine driver, or if either of the guards wishes to make a signal to the engine driver, it is only necessary for either of them to make an opening into the pipe (by means of a valve provided for the purpose), and immediately the air enters freely into all the bellows, and the whistles both in the guard's van and on the engine commence and continue to sound as long as the air is admitted to them. In the case of the passengers, the valve is of such construction that when once opened it cannot be closed again, and the signal is therefore a continuous one until the guard arrives, who has means of closing it. In the guard's van and on the engine a simpler valve is provided, which can be opened and closed at pleasure, by which means they can signal to each other as often as they find necessary. In the event of one part of the train becoming accidentally detached, of course all the whistles will commence instantly sounding. The object of the air chamber *e* is two-fold; one is, that of bringing the valves and whistles into a part of the van where they can be readily heard and attended to (in the event of their requiring attention); the whole apparatus is, in fact, readily removed bodily, and exchanged for a new one as often as requisite, all the connections being formed by short lengths of vulcanized india-rubber tubing. The other object is that of preventing too high a vacuum in the main tube, which would be objectionable, as tending to create a greater leakage, which, if very considerable, would be ejected through the whistles in sufficient quantity to cause them to give a constant sound, which might in an extreme case occasion some difficulty in distinguishing it from the intentional signals. Mr. Clark prefers to work with a vacuum of not more than 5 or 6 ounces on the square inch, the requisite degree of vacuum being obtained once for all by duly apportioning the relative sizes of the bellows, and of the air chamber *e*. Although in the engraving a bellows has been shown as the means of producing the vacuum, a pump is equally suitable for this purpose.

Fig. 2 shows an arrangement in which a small cylinder has a piston working loosely in it, and carrying a hammer, which at every stroke of the pump or bellows, strikes a gong or bell. The hammer is pressed home against its stop by a light spring *k*, and when in this position the piston closes the cylinder, and at every impulse of air from the bellows it is driven forward, and the hammer strikes the bell, at the same time it discloses slots *l* in the side of the cylinder which allow the air to escape, and the piston is pressed back again by the spring *k* to its normal position ready for another stroke As soon as the exhaustion of the main pipe is complete, no more air can be forced into the cylinder, and therefore the bell remains silent.

Fig. 3 shows a portion of a carriage with a part of

Digitized by Google

the main pipe *f* fixed beneath it. This pipe is of ¾in. wrought-iron gas pipe, at each end of the carriage it is bent downwards, as shown at *m m*, and a short length of flexible india-rubber pipe *n* is attached to it by a union joint, and when out of use is allowed to hang loosely, or to lie over a hook conveniently placed to sustain it. When the carriages are coupled up, these pipes are connected by a joint *o*, which is shown separately in fig. 4. *p p*, fig. 3, show the means of communication for the passengers; a branch *p* is led up from the main pipe *f* between the divisions of the carriages, at the top is shown a T-piece which opens into either compartment. These openings are closed by metal plugs provided with handles, which, by the application of force, may be drawn out so as to admit air, and give signals to the guards' vans and the engine. The plugs when fixed have ornamentally printed discs of leather or paper glued over them, with instructions as to their use. The leather is permanently torn away when the plug is removed, so as to indicate the compartment in which any signal was given, the plugs are also provided with expanding spring edges, as shown in fig. 5, so that when once removed they cannot be re-inserted in the same hole.

Fig. 4 shows the method of coupling the carriages together. *n n* are flexible india-rubber tubes attached to the main pipe *f*; *o* is a hollow spigot of wood or metal hanging to the carriage by a chain or cord, and having both its ends tapered so as to fit the india-rubber tubes, which are enlarged and strengthened at their ends for this purpose. When the carriages are coupled together, it is only necessary to take the spigot in hand and thrust its two ends into the corresponding flexible tubes; they do not require uncoupling, but are allowed to draw out of themselves when the carriages are separated. All these effects may also be obtained with a slight modification of the apparatus by the use of compressed air instead of vacuum, the pump or bellows in this case being employed to draw air through a whistle, and to force it into the tube, arrangements being made for stopping the action of the pump when the pressure in the pipe arrives at any point determined on.

With regard to the practical application of these signals, we are glad to be able to state that the London, Chatham, and Dover Railway Company are now fitting up their London and Dover tidal trains with them. The Board of Trade authorities have inspected the system, and, we believe, highly approve of it. It appears to us to be the best plan yet proposed; it meets the case of a train separated accidentally into two halves, both halves receiving warning automatically. These signals also inform all the guards in the train at once of any mishap. They are constantly thoroughly tested, for they sound slightly every time the train starts, and if they are out of order their noise becomes continuous. We hope soon to report a practical trial of Mr. Clark's system of signalling.

MANCHESTER BOILER ASSOCIATION.

AT the last ordinary monthly meeting of the executive committee of this association, the President, Wm. Fairbairn, Esq., C.E., in the chair, Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 248 visits of inspection have been made, and 577 boilers examined, 454 externally, 13 internally, 2 in the flues, and 108 entirely, while in addition five have been tested by hydraulic pressure. In these boilers 167 defects have been discovered, 6 of them being dangerous. A case of fracture was met with in a boiler 6ft. 8in. in diameter, and 34ft. long, having two internal flue tubes 2ft. 3in. in diameter, running through it from end to end. The fires were not, however, placed in the tubes, as is usual in such boilers, but under the bottom. The fracture in question occurred at the bottom of the outer shell, and at the first seam of rivets behind the fire-bridge, where it extended from rivet hole to rivet hole through the outer overlap of the plates, for a length of about 4ft. 6in. The excessive leakage which resulted necessitated the drawing of the fires, but the boiler was not stirred from its place, and no injury was done either to persons or surrounding property. It is important to call attention to this result, in contrast with that of transverse seam rending in plain cylindrical boilers, which, under similar circumstances, severs them entirely asunder, when the two ends fly apart, and frequently cause considerable loss of life. No doubt this fracture was greatly due to the mode of introducing the feed, which, contrary to the repeated advice of the association, was carried down by means of an open-mouthed vertical pipe nearly to the bottom of the boiler, and shot directly on to the plates, instead of being diffused by a horizontal perforated pipe.

A case of external corrosion was met with at the top of an ordinary double-furnace mill boiler, 7ft. in diameter, 28ft. long, and worked at a pressure of 60lb. per square inch, the boiler in question being one of a series of four set side by side. All these boilers were covered with flags, which had not been removed for some years, but on their being enrolled with this association, the owners were persuaded to raise the flags for purposes of examination. There was no reason to suspect any corrosion, and the boilers were uncovered merely as a matter of precaution, when they were all found to be more or less attacked by corrosion, and the plates on one of them to be reduced from their original thickness of 7-16th to a quarter of an inch in one place, and 3-16th in another. The corrosion in some cases arose from leakage of the fittings, in others from the practice of playing a jet upon the flags through a hose pipe to wash them down, when the water found its way through the joints of the stonework, and lodged on the plates. It is by no means a judicious plan to bury boilers in this way, beneath flag stones. They entirely conceal any defects that may exist beneath them, and are expensive to remove for purposes of examination; hence steam users are adverse to having them lifted, and thus boilers too frequently lie buried for years. It is recommended that, instead of flagging boilers over, they should be covered with an arched course of brickwork fitting the sweep of the shell, a layer either of felt, cork shavings, or other suitable non-conducting material, being placed between the brickwork and the plates. The covering should be neatly worked in around the fittings with 'bull,' or round-nosed bricks, and finished off in the same way at the front. The brickwork, if neatly laid, presents a very satisfactory appearance, is easily swept down and kept clean, which cannot be the case where boilers are covered with felt merely, or loose sand, while the openings round the fittings afford an opportunity of detecting any leakage that may occur at those parts. This plan of covering boilers is very generally adopted, and found to give more satisfaction than any other.

An instance of deficiency of water is reported as having arisen through adopting a mushroom valve as a blow-out apparatus. On its being opened, a piece of scale lodged on the seating, in consequence of which the valve could not be screwed down again, although considerable force was employed, so that the escape of the water could not be prevented, and therefore, to save the furnace crowns, the fires had to be drawn and the engine stopped. This is no isolated instance; good brass gland taps are more reliable than these mushroom valves, and they are decidedly recommended in preference.

It may prove of service to address a word of caution on the subject of second-hand boilers, since experience shows that it is a most short-sighted economy to be tempted by the low price of second-hand boilers to purchase them, and that doing so constantly leads to expense and disappointment. Boilers are seldom pulled out unless there is good reason for condemning them, and there is no economy in working those of old-fashioned construction and equipment. Two illustrations in point may be given, which have been recently met with. One of the members of the association had three boilers, which were condemned as unfit for use, on account of malconstruction. These boilers had two furnaces running into an oval flue tube, which was made of light plate, and with sides of an irregular and very weak form. Several cases of explosion having occurred on account of this malconstruction, the owner was induced to pull out these three boilers, and lay down new ones in their places. It appears that one of these condemned boilers, if not all of them, was sold to a broker, who succeeded in passing it off upon another member of the association, representing the boiler to be nearly new, though sixteen years old, and that it had been taken out merely because it was too small for the work, and had to be replaced by a larger one. The association knew nothing whatever of this re-purchase, until it transpired, on the first examination of the boiler, after it was reset in its new position, when it was recognised as one of the old ones previously condemned on account of malconstruction, and it became the painful duty of the association to report to its recent purchaser the true history of the boiler, and inform him that it was unsafe at the pressure he required, and had better be at once removed.

Another steam user, not under inspection, suffered more severely. He purchased an old second-hand boiler, and had it set on his premises, when almost before it had got fairly to work, the boiler exploded, killing four men and laying the place in ruins. Cases of difficulty arising from the purchase of second-hand boilers are so constantly occurring that it is thought well to bring the above before the notice of the members, and at the same time strongly to urge upon them to have nothing to do with the purchase of second-hand boilers, except in those few cases where there has been a good reason for their previous removal, and they have been originally made by a boiler maker whose name is a sufficient guarantee for the quality of the plates and soundness of the workmanship.

The list of explosions for the past month is a heavy one, as many as six having occurred, by which fifteen persons have been killed, and fifteen others injured. Particulars of four of these have been already obtained, and it has been found as before, that there is no mystery whatever as to their cause. Not one of the boilers in question was under the inspection of this association. The following is a statement of explosions from October 26th, 1867, to November 22nd, 1867, inclusive;—No. 23, November 6, portable multitubular, wagon-shaped, internally fired, 2 persons killed, and 2 persons injured; No. 24, November 7, plain cylindrical, externally fired, no one injured; No. 25 November 11, plain cylindrical, egg ended, externally fired, 3 persons killed, and 8 persons injured No. 26, November 14, agricultural, 3 persons killed, and 2 persons injured; No. 27, November 14, double-furnace "breeches" internally fired, 4 persons killed, and 1 person injured; No. 28, November 21, particulars not yet fully ascertained, 3 persons killed, and 2 persons injured; total, 15 persons killed, and 15 persons injured.

No. 23 explosion occurred at a farm, at nine o'clock on the morning of Wednesday, November 6th, and resulted in the death of two persons, as well as in injury to two others. The boiler, which was a portable multitubular one, employed for driving a thrashing machine, was not of the locomotive type, as such boilers usually are, but of wagon shape, the bottom being arched up into a horse-shoe shape sufficiently high to contain the furnace within it, the flat sides being strengthened with seven stays, three-quarters of an inch diameter, passing through the water space, while the small flue tubes, eight in number, were placed above the furnace, the chimney being at the firing end of the boiler. Its size was very diminutive. It measured only 6ft. 5in. in length from end to end, including the smoke box, 3ft. in height, and 2ft. 4½in. in diameter at the wagon head, while the plates were thin, being only a quarter of an inch in the shell and furnace. The explosion occurred as the engine was at rest, which it had been for some ten minutes, to afford an opportunity of adjusting its position, the fire burning meanwhile, and no steam escaping from the safety-valve. The boiler gave way in the external shell, rending from end to end, immediately above the longitudinal seam of rivets at the bottom of the water leg on each side of the furnace, and also through the ring seam of rivets at each end of the boiler, so that the outer casing was completely stripped off from the furnace, smoke box, and flue tubes. The explosion was attributed at the inquest to the carelessness of the attendant, who, it was said, had worked the boiler with too little water, and too much steam, the coroner and jury contenting themselves with censuring the poor man, who had been killed by the explosion, while they hinted in addition that had he survived it would have been their duty to have brought him in guilty of manslaughter. Abuse of the poor fireman, however, is by no means an exhaustive treatment of this explosion: there are other points to be considered. The boiler was ill adapted to bear high pressure, though it had been warranted when purchased, as stated by the owner at the inquest, to work up to a pressure of 100lb., and to bear one of 200lb., while it had been worked at times up to 70lb. Also the complement of fittings was defective, since, although there should have been two safety-valves, there was but one, and that of a most dangerous construction, as frequently pointed out on previous occasions, since it was weighted with a spring balance, not fitted with any ferrule to prevent its being overscrewed, and is reported to have been found locked fast after explosion. Had this boiler been suitably constructed and equipped, the explosion would not have occurred, and the lesson to be drawn from it is not the carelessness of engine drivers, but the danger of turning out badly-made and badly-equipped portable agricultural boilers, and more especially so since they do not receive the most skilled attendance.

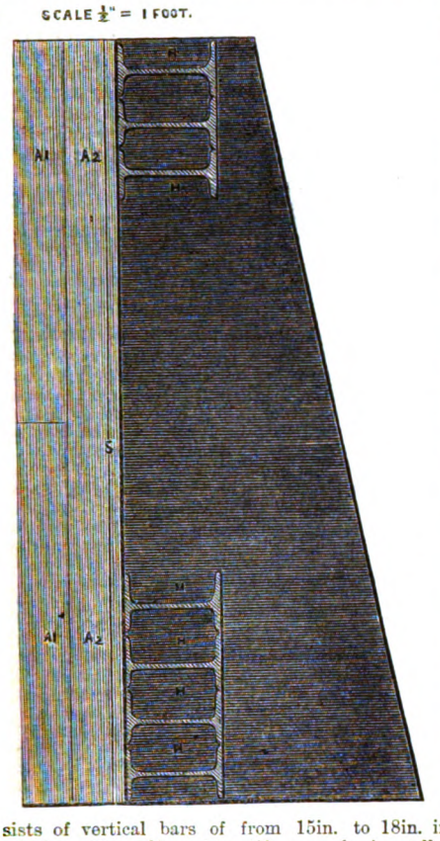
THE GIBRALTAR SHIELDS.

WE have occasionally noticed the Gibraltar shields, and in our article on Sir John Brown's 15in. armour-plate, we especially called attention to their faulty construction. It will appear incredible that in spite of their failure under trial these shields are being used for the defences of Malta and Gibraltar. The recent trials of these shields invest them with a new interest, so we give in the annexed engraving an accurate section of one of them. They are intended to protect the guns in the embrasures of the stone forts of the important works for which they were designed. The principal armour consists of the plate A_1, which is 5½in. thick, and of the plate A_2, which is 5in. thick. A_1, or the front plate, consists of two horizontal plates, 12ft. in length by 4ft. in width. The port-hole is cut out of one-half of each plate. The second plate of 5in. at the back con-



sists of vertical bars of from 15in. to 18in. in width. The 1½in. skin (S) runs horizontally, parallel with the outer plate, and in three widths; one above, one below, and one on each side of the porthole. The whole is stayed by two angular struts, as shown in outline. Between, and attached to these struts, as well as riveted to the inner skin, and the H-girders, indicated by the H's in the cut. These structures are bound together by a plentiful supply of Palliser bolts 3in. in diameter. As will be remembered, these so-called Palliser bolts are simply common bolts with the shanks diminished. The bolts were, in fact, formed as usual, that is to say, countersunk heads, reaching at the top of the frustrum of the cone to about the half of the thickness of the plate, were united to a shank, threaded at the other end, and secured at the inside by means of two nuts. It must also be noted that these Palliser bolts were themselves protected with the usual Admiralty india-rubber washers. It has also been denied that the bolts employed were on Major Palliser's plan, but we are able most distinctly to affirm the fact. Such are the Gibraltar and Malta shields as represented in the target lately tried at Shoeburyness.

The construction and proportioning of these shields being now clear, it will be interesting to note more particularly their practical performance under fire. It was intended by the authorities of the War Office that these shields should afford protection against the heaviest shot. But, perhaps, somewhat in the spirit that caused Don Quixote to refrain from trying his mended helmet, the only gun used at the first trial was the 9in. Woolwich gun, and that only with 37lb. charges: the regular service charge being, as will be remembered, 43lb. The firing was from seventy yards. The result may be told in a few words; the first shot struck at about the middle of the lower plate on the left side of the embrasure and broke nine of the Palliser bolts, sweeping the nuts, washers, and threaded portions, &c., right over the breach, with a clearing effect similar to that of canister shot. Almost every gunner behind the embrasure would have been disabled. The second shot struck fairly in the middle of the other side of the shield, carrying away ten bolts in a similar way. This constituted the first trial. It naturally proved so unsatisfactory that Sir John Pakington, extremely alarmed, called together a new Iron Plates Committee to inquire into the cause of the failure. In the meantime, this same shield was being prepared for a second trial.

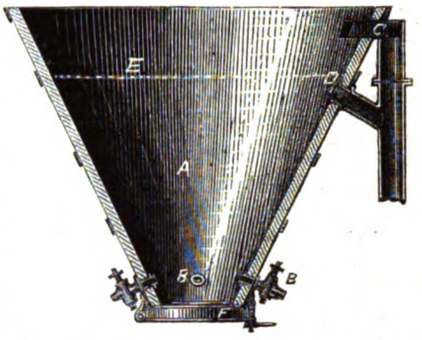
This took place on the 19th of December last. The preparations chiefly consisted in attempts to guard against the snapping of the bolts. The inner half of the outer plate at the boltholes was bevilled away to a diameter of 4in., which diameter was continued through the second plate and the inner skin. The 3in. bolt was then surrounded by a packing of ash wood. The conical heads of the bolts were smeared with emery (?) to prevent them from drawing! Behind the inner skin were fixed washers, underneath the nuts, and some 8in. square. These washers consisted of a patent cork material, already described in our pages. The second series of experiments, conducted on the 19th, consisted of four rounds from the Woolwich 9in. gun, one round from the 15in. Rodman—in all cases at seventy yards range. The first round from the 9in. gun, with a charge of 37lb., and with a Palliser shot of 248lb., hit the upper plate, creating a large gap in the 1½in. plate in the rear of the shield. The nut of one of the 3in. bolts was broken clean off. The second round, from the same gun and the same charge, with a similar projectile, hit on the opposite side of the embrasure. The depth of penetration in the shield was in this case 10in. Two of the H-girders were broken right through, and amongst the fragments lay several "bolt tails," as they are called at Shoebury. The two lower girders were also fractured.

The third round was from the 15in. Rodman gun, fired with 50lb. of L.G.R., or large-grained rifle powder, which is considered equal to 60lb. of American powder. The shot used was a cast-iron shot of 451lb. After grazing the ground for a distance of about 15ft., which of course much lessened its velocity, the shot hit on the lower plate near the left end, or the strongest part of the shield. It struck the head of a through bolt, the nut of which was consequently driven 60ft. to the rear. Large portions of the H-girders were carried away, one of the pieces measuring 2ft. 10in. by 7in., and another 22in. by 10in. Washers, nuts, bolt-tails, and rivets, were scattered around in one indiscriminate shower. The fourth round consisted of a Palliser shell, from the 9in. gun, propelled by the full service charge of 43lb. It struck fair in the middle of the shield and completely penetrated the target; a large triangular piece of the front plate being carried some 15ft. to the rear. Two bolts were broken at the threads, and a third twisted almost into a corkscrew. The rope mantlet in the rear, consisting of a matting of plaited ropes hung up to stop the fragments, was cut up by the pieces. The back skin (S) was thrown back and doubled out at right angles, and a piece of it, about 15in. square, was carried right away. The head of the shell was found some 15ft. to the rear of the target, together with fragments of the first and second plates, and several nuts and washers. The fifth and last round, similar in character to No. 4, hit the upper corner of the shield, one of the very strongest parts. It knocked out one of the Palliser bolts, but the shot stuck in the target.

IMPROVED METHOD OF TREATING ANIMAL CHARCOAL.

WHEN animal charcoal has been employed to decolorize syrups or saccharine solutions, it gradually absorbs lime and other earthy or alkaline substances, by which its decolorizing and absorbent powers are diminished. It then has to be cleansed preparatory to its re-use, and much care and skill are required in this operation, which is performed in various ways. The most recently-announced method is that patented by Mr. John Stenhouse, a chemist, of 17, Rodney-street, Pentonville, in conjunction with Mr. James Duncan, sugar refiner, of Clyde-wharf, West Ham, Essex.

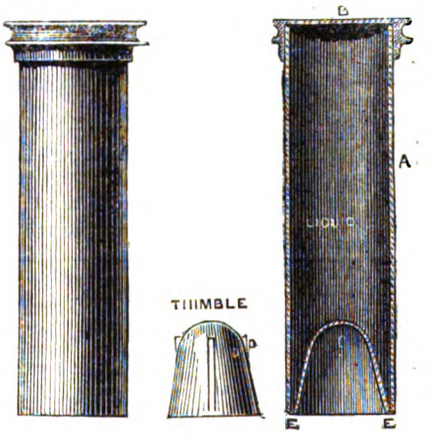
In carrying out their process the inventors take the used charcoal and wash it well with boiling water, and then introduce it into a suitable tank or cistern containing hot water slightly acidulated with nitric acid. The quantity of nitric acid used should not be more than sufficient to neutralize the lime and other earthy or alkaline substances present in the charcoal, as if an excess of the acid were employed it would di solve out a portion of the phosphate of lime, and thus injure the texture of the charcoal. It is necessary to ascertain by a preliminary experiment on a small scale the quantity of acid required in each case to neutralize the lime and other basic substances present in the charcoal, since their amount varies considerably. When the charcoal and acid solution have been digested from half an hour to one hour, which is best effected by blowing steam into the mixture, the saline solution, consisting chiefly of nitrate of lime, is removed, and the charcoal repeatedly washed with either hot or cold water until all soluble impurities are removed. When dry it is ready to be re-burned and is again fit for use. This process can also be advantageously applied to new animal charcoal before it has been used in sugar refining, as it removes impurities naturally present in the charcoal which diminish its discolorizing and absorbent properties.



The tank employed in washing the charcoal is shown in our engraving, which represents a sectional elevation of the tank and fittings. A is the vessel for holding the charcoal to be treated, which is constructed of wood, and is provided with sloping sides. In the sides of this tank near the bottom are fitted a series of cocks B B for the admission of steam or water under pressure. Near the upper edge of the tank is an overflow pipe C for the escape of the washings, and beneath this is a pipe and plug D for drawing off any excess of water from the surface of the charcoal, the level of which whilst under treatment is represented by the dotted line E; a flap door F is hinged to the bottom of the tank and secured by a fastening *a* for the purpose of discharging the charcoal after it has been cleansed.

CIRCLE MARKER.

THE present method of marking circles adopted by iron shipbuilders, boiler makers, &c., is clumsy, and is often the cause of bad and inaccurate punching. The annexed engraving shows an instrument recently invented by Messrs. Johnson and Woolley, and which gets over the above difficulty, and insures accuracy in marking circles for rivet holes on sheets, bars, &c., previous to being



punched. A is a piece of brass tubing, B is a brass top or lid screwed on to A, for the purpose of keeping the liquid in the tube, C is a brass thimble fitted into A by means of three ribs D D D cast on the thimble C. The tube A is filled with liquid whiting, which flows round the thimble C, and finds its way to the opening E E, and, when used, leaves the ring or circle required. By the use of this instrument the circles are clearly marked, and accurate and expeditious punching is so far insured.

As an illustration of the great amount of work done by screw colliers, it is stated that the "Haswell" (s.s.) made sixty voyages from Sunderland to London last year, forty-one of that number being made between the 20th of May and the end of December.

A NEW SYSTEM OF LIGHTING.

A DISCOVERY has been made by a chemist of Paris which promises to supersede gas for illuminating purposes. The discoverer is an assistant to MM. Tessier du Mothay and Marechal, by whom a trial of the system has just been made in Paris with perfect success. The light produced is of the purest white, and admits of the most delicate shades being distinguished. The discoverer had no idea of inventing anything new as to the lighting of cities. He was merely experimentalising with the hope of discovering some means of taking photographs at night when he hit upon a new and magnificent light. The combustion of ordinary gas by oxygen is the principal secret of the process. A small cylinder of magnesium interposed in the centre of a jet in combustion becomes luminous, and produces a quantity of light measured at sixty times that which would be produced by ordinary gas, or about £2 3s. 2d. worth of gas for 7¼d. We have received from Paris the details of this invention, but only just as we were going to press, so that we are obliged to postpone their publication for a week.

PROPOSED CONFERENCE ON TECHNICAL EDUCATION.

IN the MECHANICS' MAGAZINE for December 20th last, we published a notice of a conference on Technical Education, which is proposed to be held at the House of the Society of Arts, in the Adelphi, on Thursday and Friday, the 23rd and 24th of the present month. The council propose the following programme of the topics for discussion at the meeting. As the council have reason to expect that the conference will be numerously attended, and it is only to sit for two days, it is thought desirable that it should deal rather with general principles than with details, and that the latter should be taken up more deliberately by the committee which it is proposed should be established:—

1. The necessity for improved national education for the working classes generally. (*a.*) Improved primary education, and the measures necessary for securing the same. (*b.*) Additional facilities in primary schools for affording the elder children the means of learning the elements of scientific knowledge.

2. The necessity for the establishment of schools for technical and industrial education in relation to science and art, in which pupils, after leaving the primary schools, may obtain instruction suited to the special industries with which they may be connected, as workmen, foremen, or managers.

3. The best measures for securing the foregoing object.

4. How far technical education can be promoted by the aid of existing educational endowments.

5. To request the council to appoint a standing committee of members of the Society of Arts and others, to take whatever steps may be required to advance the objects approved by the conference, and to send deputations to the Government, to support such applications as may seem desirable.

The chair will be taken each day at twelve o'clock, by William Hawes, Esq., F.G.S., chairman of the council.

Legal Intelligence.

COURT OF CHANCERY.

January 14.

(Before LORD JUSTICE LORD CAIRNS.)

BOVILL V. HITCHCOCK.

OUR readers are doubtless familiar with the numerous suits instituted by Mr. Bovill for the protection of his well-known patents for improvements in the manufacture of flour. The present application was an appeal from an order of the Master of the Rolls refusing an application by the defendant that the trial of certain issues of fact, in respect of which his Lordship had already ordered that the evidence in chief should be taken viva voce at the hearing, should take place before his Lordship with the assistance of a jury.

For the appellant, it was contended that, inasmuch as under the old practice of the Court of Chancery a patentee was always required to establish his patent at law, which involved a trial of questions of fact by a jury, notwithstanding the new Act (known as Sir J. Rolt's Act), which imposed on the Court of Chancery the duty of deciding questions at law, the defendant in a patentee's suit was entitled as a matter of right to have the questions of fact arising upon the patent tried by a jury. They also urged that there were questions of fact arising in the present case which, notwithstanding the frequent litigation which has taken place upon this patent, had never yet been submitted to a jury, and that the Master of the Rolls had in another case on the same patent expressed himself strongly in favour of the plaintiff.

Mr. Little and Mr. North appeared for the appellant, and Mr. Baggallay and Mr. F. Harrison for the plaintiff, but the latter gentlemen were not called upon.

Lord Justice Lord Cairns said that he thought that the effect of Sir J. Rolt's Act was to throw on the Court of Chancery the duty of deciding legal questions, but that that duty was to be discharged according to the ordinary practice of the Court. No abstract right was given to the parties to demand a jury. It appeared to his Lordship to be a fallacy to say that under the old practice the Court required in patent cases the verdict of a jury. What the Court did require was the judgment of a court of law upon a question of legal right, which the Court of Chancery had then no jurisdiction to determine. The verdict of a jury was merely an incident of the proceedings at law. It appeared, therefore, to his Lordship that under the present practice the question whether there should or should not be a jury must be determined upon the facts of each particular case. With regard to the argument that the Master of the Rolls had already expressed an opinion in favour of the patent, that would be an argument for the case not being heard by him at all, which, however, was not the present application. The Master of the Rolls' attention had been called to what he had said in favour of this patent in the previous case, and, notwithstanding that, his Lordship (the Master of the Rolls) thought that this case could be conveniently tried before himself without a jury. Except on this ground, it had not been argued that the case could be determined better with the aid of a jury than without. Though his Lordship entertained very great respect for the institution of the trial by jury, yet his experience in patent cases led him to think that many points in those cases could be better determined by a judge without the aid of a jury. His Lordship would always be unwilling to interfere with the discretion of a primary judge as to a trial to take place before himself unless there was a very strong reason for doing so. Appeal dismissed with costs.

COURT OF EXCHEQUER.

January 13.

(Sittings in Banco, before the LORD CHIEF BARON, MR. BARON MARTIN, MR. BARON CHANNELL, and MR. BARON PIGOTT.)

PLATT AND OTHERS V. HIGGINS.

THIS was a patent cause tried in June, 1865, when all the issues were found for the plaintiffs.

The plaintiffs are patentees of improvements in carding engines, relating to the use of clearing combs for clearing the working rollers of the machine.

The defendant moved for a new trial on the ground that carding engines constructed with rollers and clearing combs, like those patented by the plaintiffs, were described in the specification of a patent of a Mr. Birch, dated 1837, and the defendant contended that as he had only used Birch's improvements, there was no evidence of infringement, or of the novelty of the plaintiff's patent.

Mr. Grove, Q.C., and Mr. Aston showed cause against the rule, and Mr. Manisty, Q.C., and Mr. Macrory supported it.

COURT OF ADMIRALTY.

January 14.

(Before the RIGHT HON. SIR R. PHILLIMORE.)

THE "GREAT EASTERN."

TWO cases were heard in connection with this unfortunate vessel. The first was a suit for repairs and necessaries, and came before the Court upon a motion for leave to file an answer to the amended petition. The defendants, the owners of the "Great Eastern," contend, firstly, that, as a matter of law, they are not liable for the repairs and alterations in question; and, secondly, upon the facts, that such repairs and alterations were done in such an unworkmanlike manner as to be of no benefit to the ship. They, therefore, asked the Court to allow them to plead the whole case, so that if upon the hearing the question of law were decided against them they might upon the facts of the case raise the question of their liability. It was suggested by the Court and agreed to by counsel, that the defendants' answer should be filed, and that another application should be made to the Court for direction as to how the facts of the case should be dealt with.

The second cause heard was a wages suit, in which the pleadings had been filed, and annexed to the defendants' answer were two schedules, the first being a list of the seamen who had accepted sums of money in discharge of their claims, and the second those whose claims were still outstanding, and in respect of which a sum of money had been paid into court. Since the filing of the pleas certain of the persons on this list had accepted sums of money in discharge of their claims.

The Court was now moved to allow the defendants to remove the names of the persons in question from the second list, and to add them to the first. This was opposed on the ground that the men, being very needy, had, without the knowledge of their solicitor, consented to accept the defendants' offer, and that, although they had signed a release, they were not thereby debarred from continuing parties to the suit.

The Court allowed the transfer of the names without prejudice as to the sufficiency of the release.

Mr. V. Lushington appeared for the plaintiffs, and Mr. C. P. Butt for the defendants in both suits.

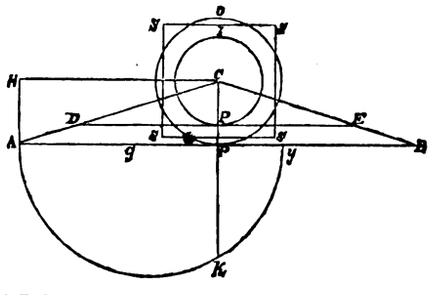
Correspondence.

SQUARING THE CIRCLE.

LETTER II.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—The area of a circle is equal to that contained between two parallel lines whose joint length is equal to the length of the circumference and distance apart equal to that of the radius. Let the bases A B and D E of the triangles A B C and D E C equal the lengths of the circumferences of the circles O and I respectively. As A B is equal to O, and D E is equal to I, and being upon a common parallel P P; therefore, the area contained between the two bases is equal to that contained between the two circles (equal areas are contained between equal parallels of the same length), and the same would be true of any other circles described within I until terminated in a central point; therefore, the circle O and the triangle A B C have equal areas. Again, the circle O has the same relative proportion to I which the base A B has to D E, but the areas contained between them are equal; therefore, the remainders are equal, i.e., the circle I is equal to the triangle D E C. Then the circle O contains an area equal to the triangle A B C, and is equal to fig



A P C H, which is two straight parallel lines of a joint length equal to the circumference of the circle O, their distance apart being that of its radius C P P. The proportional line K is formed by taking the mean of length and height, and with it G as a centre describing the semicircle A K Y. A line let fall from P to K gives the side of the square S S S S, which is the square of the circle O, and as far as I can see geometrically proved. But upon that point I shall reserve my felicitations, seeing the fate of Mr. Harvey, until it has received the sanction of some of your able correspondents, and gone through the public mill. In my next I propose to approach the circumference.—I am, Sir, yours, &c.

JOSEPH A. NICHOLSON.

3, Adelaide-place, London-bridge,
January 14.

SQUARING THE CIRCLE.

SIR,—I have been both interested in and amused by the discussion in the MECHANICS' MAGAZINE upon the question of Circle Squaring. I do not propose to enter upon the matter at any length, but simply to observe that I think Mr. Harvey has more or less muddled the matter. The strongest arguments against him, to my mind, is summed up in the following question—What would be the worth of our "Nautical Almanac" if he were correct?—Yours, &c. R. N.

Pembroke, January 12.

Digitized by Google

Meetings for the Week.

MON.—Royal United Service Institution.—At 8.30 p.m. Major G. B. Fosbery, V.C., H.M. Bengal Staff Corps, on "Explosive Bullets, and their Application to Military Purposes."

Society of Engineers.—Presentation of Premiums for 1867, and President's Inaugural Address, at 7.30; also a Special General Meeting for Consideration of Rules, at 8.30.

Royal Institute of British Architects.—At 8.—Mr. Edward I'Anson on "The Architecture of Moscow."

TUES.—The Institution of Civil Engineers.—At 8 p.m.—Renewed discussion upon the papers on "The Victoria Bridge," and on "New Railways at Battersea, etc."

FRI.—Royal Institution.—At 8 p.m.—Professor Tyndall on "Faraday as a Discoverer."

SAT.—Royal Institution.—At 3.—Professor Roscoe on "The Non-Metallic Elements."

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10s. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—Messrs. S. Bros.—G. W. H.—T. J. T.—J. N.—J. B.—D. V.—F. N.—H. S.—A. G. S.—R. J.—R. F. F.—M. J.—P. T.—F. H.—H. W. D.—R. F.—J. B. T.—T. C.—G. E. P.—C. W. S.—W. A.—Messrs. C. and C.—A. W.—B. R.—P. E. C.—C. H.—S. N.R.—M. B.—W. P. M.—J. B. P.—R. G. S.—S. A.—W. P. N.—Messrs. L. H. and Co.—J. M.—L. C.—W. W. K.—J. G. A.

Want of space obliges us to defer the publication of a long letter from Mr. Harvey, as well as several other communications, until our next.

Naval, Military, and Gunnery Items.

THE next examination for direct commissions will begin on the 1st of April.

THE "Arrogan," recently sold out of the navy, has left Portsmouth harbour for the shipbreaker's yard on the banks of the Thames.

THE tree at Yokohama under which Commodore Perry, United States' Navy, signed the original treaty with the Japanese, has been cut down, to make way for the residence of the British Consulate.

IT is rather ridiculous to read of H.M. ships "Buster" and "Monkey" doing solemn duty here and there. Could not the godfathers of H.M. ships find more dignified names than they do for some vessels of our fleet?

THE Royal Mail Company's steamship "Seine," just arrived, made the passage home with one wheel only, having broken the port paddle shaft 200 miles south of Bahia, and remained four days at Bahia securing wheel.

A TOULON letter in the "Messager du Midi" announces that fears are entertained of the loss of the French war corvette "The Rolland," 400 horse-power, eight guns, and 195 men. Having been caught by a squall while off the coast of Syria, she was driven ashore, and was considered in danger. The crew were saved, as were also the ship's stores.

THE Austrians have lately made experiments at Fiume with a new species of torpedo, the peculiarity of which is, that it can be set in motion under water, and directed against the object to be destroyed. Its use therefore, if successful, will by no means be confined to the defence of coasts and harbours, as it may be equally well employed in the open sea.

THE erection has been commenced of a landing stage and pier on the Thames bank in the Royal Arsenal marsh, for the purpose of discharging building materials for the construction of seven bomb-proof magazines, with a view of insuring an additional precaution against accidents in the preparation of live shells.

WE understand that the Government have either concluded, or are on the point of concluding, an arrangement with the Irish Lights Board to blast down Daunt's Rock, the dangerous obstruction at the mouth of Cork Harbour, on which the "Research" was injured, until there shall be at least thirty feet of water above it at low water.

IT is stated that The Colt Patent Firearms Company at Hartford, Connecticut, has made a contract with the Russian Government for the manufacture of 30,000 Berdan rifles within eighteen months. They have also made a contract with the Prussian Government for 100 Gatling revolving cannon, and some of these guns are also to be built for Russia.

MARINE disasters, by fire, wreck, collision, or other accident at sea, during 1867, happened to 536 American vessels, all of which have been totally lost, and, excluding their cargoes, were valued at 21,742,200 dollars. This is a large falling off from 1866, when 571 vessels, valued at 33,794,300 dollars were lost at sea.

THE "Elk," another composite-built, unarmoured gunboat of 463 tons, has just been launched from Portsmouth dockyard. The "Elk" will carry as her armament one 64-ton muzzle-loading rifle, and one 40-pounder breech-loading rifle. Her engines will possess a combined total nominal power of 120-horse, and will drive a pair of three-bladed twin screws.

THE Hamburg-American Company's screw steamship "Germania," Captain H. F. Schweusen, sailed from Southampton last Friday for New York, with English, French, and German mails. This is the first departure of this line under the new contract with Her Majesty's Government, and the steamers will continue to leave that port every alternate Friday until the end of February, after which they will sail every Friday.

THE "New York Tribune" has a despatch from Washington which states that, notwithstanding the abrupt termination of the Alabama claims correspondence between Lord Stanley and Secretary Seward, information has been received there that Mr. Thornton, the new British Minister, goes out empowered with full authority to reopen the question, and will present for the consideration of the United States a new plan of adjustment.

THE "Blanche," recently commissioned at Sheerness, was taken for a preliminary run on Thursday week, previous to the trial of her machinery on the measured mile. The vessel was timed on the mile for two runs, when an average speed of upwards of 13 knots was attained. The engines, built by Messrs. Miller and Ravenhill, worked exceedingly well, and it is believed the vessel will answer the utmost anticipations of her designer.

FROM Japan we learn that Osaca and Viogan, or the inland sea, were to be opened to foreign commerce on the 1st of January, 1868. The new port to be opened on the west coast of the empire is Neagata; but the harbour at that place being unsafe for foreign ships coming in, that of Ebisunito, on the island of Sado, thirty miles distant, is to be made the port of entry in its stead. This port and harbour are to be opened on the 1st of April.

WE are glad to be able to report that the Floating Obstruction Committee have at last carefully investigated the principle of Captain Harvey's Torpedo. We believe that they are so favourably impressed with its merits as to direct some trials to be made with it. We are glad to learn this, as well for the gallant Captain's sake, who has so untiringly devoted himself to its development, as for that of the country, which stands in a fair way of possessing the most perfect weapon of its kind extant.

THE actual waste of seamen in the financial year ending with March, 1867, was 4,077—viz., 1936 from casualties (death, invaliding, desertion, discharges with disgrace, by purchase, or on pension), and 2,141 by being paid off to the shore, or other causes. In the same year there were 1,899 entries from the training ships for boys into sea-going ships, and 95 men were otherwise entered in the navy, men of the "pure seamen" class. The actual number rated in the year as ordinary seamen, of the pure seamen class, was 2,399. The average number of boys in the training ships in the year was 2,811; in the last quarter of the year, 2,967. The actual number rated as ordinary seamen, pure seamen, was only 1,899 in the year 1864-65, and only 1,470 in the year 1865-66; and the waste of seamen was as many as 5,328 in the former of these two years, and 4,369 in the latter. In both respects, and also in the number of boys in the training ships, and the number transferred thence into seagoing ships, the latest year, 1866-67, shows much the best account.

Miscellanea.

THE imports of bullion for 1867 were £25,000,000, against £34,000,000 for 1866, while the exports were £14,000,000, against £22,000,000 for 1866.

THE railway from Nice to the Italian frontier, belonging to the Paris, Lyons, and Mediterranean Company, is now completed.

DURING the past week broccoli was despatched from West Cornwall to London and the chief provincial markets at the rate of seventy to ninety crates a day.

IT is understood to be the intention of Government to confer a title on Professor Wheatstone, in consideration of his great scientific attainments and of his valuable inventions.

THE lava is still flowing copiously from the crater of Mount Vesuvius. The stream of lava is from 7 to 8 metres high and from 50 to 60 broad. Shocks and explosions are frequent, and it is not likely that the eruption will soon cease.

THE police reports of New York city show that during the year ending November 1, 79,925,000 persons crossed over the ferries leading from that city to Brooklyn, Jersey city, and the other towns around New York bay. This vast number is double the population of the United States.

FOUR locomotives will be shortly at work in Abyssinia upon the railway formed in connection with the English expeditionary force now in that country. Two of these locomotives were obtained from the Kurrachee Harbour works, one from the Bombay, Baroda, and Central India Railway, and one from Messrs. Wells and Glover.

ON Monday, a boiler explosion occurred at Beckworth Colliery, near Newcastle. Though considerable damage was done to property, fortunately no lives were lost. The boiler that exploded was only erected a few weeks ago, and was employed in generating the steam required at the mouth of the pit. The men at work escaped by means of a shaft in another part of the workings.

AN extraordinary phenomenon is reported from Niagara Falls. A strong wind so pressed back the waters of Lake Erie that the waters of the falls fell twenty feet. The American fall could be passed on foot. A great many curious and unsuspected rocks and holes were revealed, and the pit below the falls presented a wonderful appearance. Such a decline of the waters has never been known before.

THE Society of Arts has issued invitations for a Conference on "Technical Education," to be held in its rooms on Thursday and Friday next week. A very full meeting is expected. Earl Russell, Earl Granville, representatives from various Chambers of Commerce, and other public bodies, and mayors of towns, the seats of leading industries, have already signified their acceptance of the Society's invitation.

THE Seine is entirely frozen over, a circumstance which has not occurred for twenty years. The accounts from the departments announce that the Loire is floating down a quantity of ice; the Saone is frozen over at Lyons between the Pont de Serin and the Pont Mouton; the Rhone is beginning to send down large blocks; the Sarthe and the Breante are frozen over in several places, as is the Indre at Nantes.

A CHRISTMAS treat was lately given to the aged poor of Bideford, Devonshire, by Mr. Pridham of that town. Twenty of those present were upwards of eighty years of age, and several of them were veterans who had fought at the Nile, Trafalgar, and Waterloo. One of them, John Barry, is ninety-three years of age; he fought in most of the Peninsular engagements, and was in Picton's brigade. His faculties are wonderfully vigorous.

THE number of passengers conveyed in Belgium during last September was 1,398,907, with 543,917 tons of heavy goods, 11,669 of parcels, and 85,152 packages of specie. The receipts were 3,622,013f., of which passengers produced 1,676,079f.; heavy goods, 1,458,547f.; parcels, 235,161f.; luggage, 92,981f.; bullion, 19,958f.; and horses, cattle, &c., the rest. The total sum shows an increase of 503,800f. over the same period in 1866.

A SMUGGLER'S cave has been discovered in Ireland. A pier has just been finished on the shore below Kilkeel, where a small river empties itself into the sea. The men employed in removing the shingle to enlarge the accommodation, came on an old cave roofed and full of tobacco. Some forty or fifty rolls were perfectly useless. It must have been upwards of twenty years buried, and is at the spot where the fishing boats are drawn up. Nobody seems to know anything respecting it.

DR. CHADWICK, who formerly resided and practised at Bolton, intends to offer £10,000 to be applied to the erection of working men's model cottages in that town, the rentals from which are to be devoted to the maintenance of an orphanage which he proposes to erect. In the first instance, the orphanage will be for the admission of girls, but it will ultimately be extended so as to receive boys; and to carry out this benevolent design a sum of about £17,000 will be required,

A CURIOUS phenomenon was noticed at Blackheath, on Saturday last. Rain had fallen for some hours; and a frost supervened, upon which every leaf was covered with a coating of ice, having an icicle depending from the tip. The whole icy coating was separated from the leaf without breaking, being a facsimile of the leaf in ice, with every vein and indentation clearly marked. These delicate casts appeared as if moulded in glass, and retained for a time all the form and character of the leaves from which they were severally taken.

THE plan of a railway connecting Dalmatia with the Brenner Pass has now been adopted, and arrangements have been made for completing the line by 1870. It is to pass from Fiume by St. Peter, Laibach, Villach, and Franzensfeste, where it will join the Brenner line. The construction of the railway would make Franzensfeste an important strategical point, and the Austrian Government has accordingly ordered the fortifications in the district surrounding it, especially those in the direction of the Pusterthal and of Brixen, to be considerably strengthened.

THE large slate quarries of Grands-Carreaux, France, have just been entirely buried by an earthslip, and three lives lost. The works on the previous evening were observed to be in a dangerous state, and all the labourers were withdrawn. Eighteen hours later the overseer, named Choinet, and two men were engaged in fixing barriers to pre-

Digitized by Google

vent anyone from approaching the entry, when the earth sunk in beneath them for an extent of two acres, and to a depth of 200ft., and buried them in the ruins. Their bodies have not yet been recovered. The material loss is estimated at £8,000.

A NEW YORK paper publishes a special dispatch from Havana, to the effect that the Spanish Government has offered, through the American Minister at Madrid, to sell to the United States the islands of Cuba and Porto Rico. The price asked is 150 millions of dollars, in gold, payable in three equal instalments, the first payment to be made when the treaty is signed, the second, one year thereafter, and the last at the end of six years. The inhabitants of those islands are represented as being generally in favour of transferring their allegiance.

THE visitors to the South Kensington Museum during the week ending January 11, were:—On Monday, Tuesday, and Saturday, free, from 10 a.m. to 10 p.m., 5,749; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,237; total, 6,986. Average of corresponding week in former years, 9,832. Total from the opening of the museum, 7,143,810. Patent-office Museum, South Kensington.—Number of visitors for the week ending January 11, 2,341; total number since the opening, free daily (12th of May, 1858), 1,229,196.

MR. BIGELOW, late United States Minister to France, discovered in Paris, and took back with him to America, the original MS. of Benjamin Franklin's Autobiography, from which it appears that in the edition of 1817 large and many important portions of the original were omitted. Among other things not yet published, is a graphic account of Franklin's negotiations with Lord Grenville and Lord Mansfield concerning the taxation of English proprietors in Pennsylvania, on his first visit to England as agent of that colony. Mr. Bigelow is going to prepare an edition of the autobiography.

THE North-Eastern Railway has tired of the ten hours' system. It will be remembered that on the occasion of the strike last spring one of the points conceded to the engine-drivers and firemen was ten hours per day and two hours the quarter day overtime. This has been found not to work, and this month the old system of 12 hours per day and 2½ the quarter over has been re-established. The money paid to the men per day will be the same, but some of the men who struck, and were afterwards re-employed at reduced wages, will be a little better paid. It is said the return to the old system is by way of experiment for a month.

THE tone of the Belgian iron trade appears to have slightly improved of late. The Montigny sur Sambre Company, which had only one furnace lighted, has just brought a second into operation. The affair which is at present exciting the most interest on the Belgian markets is a contract for 25,000 tons of rails required for the Poti and Tiflis Railway (Russia). As the Russian Government is energetically promoting the development of new railways on its territories, while the Prussian and Austrian Governments are pursuing a similar policy, there can scarcely fail to be an increased demand for railway iron in Europe this year.

THE following is the list of subjects offered by the Belgian Academy of Sciences, Arts, and Literature for prizes of 1,000f. each in the section of the fine arts for the year 1868.—First: An historical account of medal engraving in Belgium from the sixteenth century to the year 1794, embracing all the country at present belonging to Belgium, and including the biography of the artists as well as a criticism on their works. Second: An inquiry respecting the period at which the architecture in the Low Countries was affected by Italian influence, with indications of the persons to which such influence is attributable, and citations of works in illustration of the same.

SOME statistics collected by the Mons Chamber of Commerce show that the coal production of Belgium amounted in 1866 to 12,774,000 tons, of which 9,851,000 tons were raised in the province of Hainaut, 359,000 tons in the province of Namur, and 2,564,000 tons in the province of Liege. The exports of coal from Belgium to France amounted, in 1866, to 3,880,848 tons, as compared with 3,453.589 tons in 1865. The exports to Holland declined to 137,700 tons in 1866, as compared with 195,700 tons in 1865. The internal consumption of coal in Belgium amounted in 1866 to 7,842,450 tons, as compared with 7,506,000 tons in 1865, showing an increase of 346,450 tons; the increase in 1865 over 1864 was 380,850 tons.

THE Chiltern hills were on Saturday visited by a severe storm. The trees and hedges were covered with ice to the thickness of half an inch in the more exposed places. The trees were frozen so stiffly, that, in spite of a strong wind, they stood perfectly motionless. The houses and buildings were coated with ice on their southern aspects, giving the appearance of a glass glaze; the glass in the windows was also thickly coated. The icicles on the gates produced an extraordinary effect, every bar being covered with ice, from which were suspended rows of icicles six inches long. These could be counted by hundreds—not hanging straight down, but all inclining at an angle of about 30 deg., with the most perfect regularity, to the north, or away from the wind.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1558, 1574, 1584, 1686, 1592, 1615, 1629, 1637

BUILDINGS AND BUILDING MATERIALS—1548, 1569, 1598, 1613

CHEMISTRY AND PHOTOGRAPHY—1526, 1553, 1556, 1603, 1617

CULTIVATION OF THE SOIL, including agricultural implements and machines—1535, 1546, 1563, 1568, 1571, 1573, 1585, 1618

ELECTRICAL APPARATUS—1531, 1532, 1565, 1583, 1611

FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1544, 1555, 1582, 1599, 1602, 1608, 1609, 1636

FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1527, 1580

FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1522, 1533, 1545, 1587, 1588, 1601, 1607, 1619, 1622, 1634

GENERAL MACHINERY—1523, 1524, 1525, 1534, 1540, 1551, 1561, 1600, 1604, 1633

LIGHTING, HEATING, AND VENTILATING—1572, 1595, 1597, 1610, 1616, 1628, 1638

METALS, including apparatus for their manufacture—1549, 1550, 1559, 1606, 1635

MISCELLANEOUS—1530, 1535, 1537, 1538, 1541, 1552, 1554, 1557, 1560, 1564, 1570, 1578, 1581, 1589, 1591, 1605, 1614, 1621, 1623, 1624, 1629, 1631, 1632

ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1543, 1579

SHIPS AND BOATS, including their fittings—1567, 1620, 1627

STEAM ENGINES—1529, 1539, 1547, 1594, 1596

WARFARE—1521, 1590, 1612, 1625, 1626

1521 W. J. MURPHY. *Improvements in breech-loading firearms and cartridges.* Dated May 22, 1867.

In performing this invention the inventor proposes to attach to the breech end of the barrel of the gun or rifle a cartridge holder open at both ends. This cartridge holder is to swing on a pivot or spindle at any angle that may be required, so as to make it swing either above or below or through the side of that part of the breech made for its reception. On the cartridge holder, near where the spindle enters the swinging point or eye, will be cut two teeth, one tooth to keep the cartridge holder in its proper position when firing, the other to act as the half cock, as, until the cartridge holder passes the last tooth, it will be out of the centre, and the needle or striker, although on full cock, if it should go off accidentally, will only strike the side of the cartridge, and not the cap. On the spindle alluded to a spiral spring will press in so as to work into the teeth on the cartridge holder. When the spindle is drawn out, the teeth will be free, and if the cartridge holder be set in the side, it will swing out by its own weight ready for the introduction of a fresh cartridge, which will be introduced from the rear and push out the empty shell remaining in the holder after the explosion.—Patent abandoned.

1522 R. S. MOSS. *Improvements in wearing apparel.* Dated May 22, 1867.

Provisional protection has not been granted for this invention.

1523 W. BROOKES. *An improved lubricator.* (A communication.) Dated May 22, 1867.

This invention consists in the employment of a glass reservoir and glass tube furnished with two cocks, one to regulate the exact supply required, and the other to cut off the supply when needed.—Patent abandoned.

1524 A. M. CLARK. *An improved fabric for the manufacture of machine belting, and for other purposes.* (A communication.) Dated May 22, 1867.

This invention is not described apart from the drawings.—Patent completed.

1525 J. M. KAUFMANN. *An improved means or apparatus to be used for travelling through the atmosphere, and on land and water, part of which apparatus is equally applicable to other purposes.* Dated May 22, 1867.

This invention is too voluminous for insertion.—Patent abandoned.

1526 W. E. NEWTON. *Improvements in portable photographic apparatus.* (A communication.) Dated May 22, 1867.

This invention has for its object the construction of a convenient form of portable apparatus for taking views. The apparatus consists of a small circular box for containing fifty or more prepared glasses, and second of a camera resembling an opera glass. The two tubes of the opera glass are furnished with two lenses exactly similar in focus. One of these serves to project the image to be taken on to the ground focussing glass, which occupies the large part of the tube; the other to produce the image on the prepared glass plate, which occupies a small dark chamber formed in the opposite tube. The circular box in which are arranged the prepared glass plates is pushed over an opening in this chamber provided with appropriate grooves; the doors of the box and of the dark chamber are simultaneously opened, and a prepared glass plate falls from the box into the dark chamber. When the view has been taken, the apparatus is turned upside down, and the glass plate which has been exposed will fall back into its place in the box, which is then removed. The door of this latter closes, and a small movement to the right or left brings another prepared glass plate over the door and the opening in the camera.—Patent abandoned.

1527 A. MARTIN. *Improvements in preserving grain, and in the construction of the granaries to contain the same.* Dated May 22, 1867.

This invention has reference to the preservation of grain from the attack of insects, and consists, mainly, in so constructing the granary as to render it completely air-tight, some suitable gas or vapour being introduced which is destructive of insect life.—Patent completed.

1528 A. A. HELY. *Improvements in machinery for obtaining pressure.* Dated May 22, 1867.

This invention has for its object the combination of percussive force with hydraulic power for pressing and compressing purposes. The hydraulic parts of the machine consist of a head, support, cylinder, ram, and base, as usual, with one or more intermediate receptacles for holding the substance or material to be pressed or compressed sliding upon the supports between the pressing ram and the resisting head of the machine. According to one combination, the patentees employ a platten or false movable head placed under the resisting or main head of the machine, having one or more plungers or pistons working either through or outside the said main head, and having one or more weights, or one or more steam or other hammers, placed above the one or more plungers or pistons, so as to fall or strike upon or against it, and thereby cause the platten or false movable head to exert percussive force upon the substance or material contained in the one or more receptacles of the machine.—Patent completed.

1529 E. W. HUGHES. *Improvements in rotary engines and pumps.* Dated May 22, 1867.

Hitherto much difficulty has existed in the production of a complete rotary engine in which action and reaction are equal, and there is no loss while the piston is passing the valves; also in turbines from the rush of water only being made available; and in pumps and exhausters from the column of water not being kept always in motion, but constantly checked and started again. Now the object of this invention is to overcome these difficulties, and produce a complete rotary engine which maintains the action and reaction always the same, and all the pressure that is employed therefore effective, the pressure of the power always acting continuously according to the area of the piston and the pressure employed. The inventors accomplish this by means of an annular cylinder in which rotates a piston made tight, and carrying round with it on either side an induction and an eduction pipe; these pipes connect with the centre pipe, which also forms the axis and medium of motion. In this cylinder are placed two or more valves, as may be required, which are withdrawn as the piston passes.—Patent abandoned.

1530 F. H. JOHNSON. *Improvements in gas blow-pipes, and in blow-pipe torches or flames.* Dated May 23, 1867.

One part of this invention consists of an improved gas blow-pipe, whereby the gas jet or flame can be increased or diminished with the greatest nicety. Another part of the invention consists of an improved flame or torch holder to be used with the improved, or with any other blow-pipe, or the gas connecting tube pipe separately or combined therewith.—Patent completed.

1531 M., R., and M. THEILER, jun. *Improvements in telegraphic instruments and electric clocks.* Dated May 23, 1867.

This invention consists, first, in a mode of making electro-magnets and armatrices, the latter either of soft iron or of magnetized steel, by means of which a double motion can be given to a bar or needle, similar to that of an ordinary galvanometer or needle instrument, the needle dropping into its original position from either side as soon as the current ceases. The invention consists, second, in a peculiar kind of needle instrument, the whole contained in a circular, oval, or square box, which can be made so small and light as to be put in a pocket, and to be used if desirable in any position, and without any fastening to a base.—Patent abandoned.

1532 C. W. SIEMENS. *Improvements in the means and apparatus employed for conveying telegraphic dispatches, letters, and other light articles, through tubes.* (Partly a communication.) Dated May 23, 1867.

The present invention has for its object to obviate certain defects in the ordinary pneumatic apparatus by the establishment of a system of pneumatic tubes of comparatively small diameter, and, consequently, of an inexpensive nature, so arranged that, while the carriages or pistons travelling in the same are correspondingly of small dimensions, and, consequently, require no great power to propel them. The smallness of the capacity of these carriages is compensated for by the rapidity with which they may be dispatched in quick succession.—Patent completed.

1533 O. RODOLPHE. *A table with double face and surprise.* Dated May 23, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

1534 A. M. CLARK. *Improvements in typographic printing machines.* (A communication.) Dated May 23, 1867.

This invention is not described apart from the drawings.—Patent completed.

1535 E. HOWELL and T. HARDY. *Improvements in turnip or root-cutting machines.* Dated May 23, 1867.

This invention consists in adding a small cylinder or barrel which is placed in juxtaposition to the main cylinder or barrel of the machine, and which small cylinder or barrel revolves in the recesses through which the uncut pieces of root have hitherto passed, thus effectually preventing the slabs of the roots from going through the machine without being cut into finger pieces.—Patent completed.

1536 S. and T. ATKINSON. *Improvements in machinery for folding paper.* Dated May 23, 1867.

This invention relates to machinery for folding the sheets of paper used in the manufacture of books, also for folding newspapers, circulars, letters, and other sheets of paper requiring to be folded uniformly, and the improvements consist of a rectangular or other suitable form of framework, the top part forming a hopper of suitable size, according to the size of the sheets of paper to be folded. A horizontal platform in two parts is provided in this hopper to support the papers, and a pair of india-rubber rollers, having slightly roughed surfaces, are placed side by side betwixt the two parts of the platform with their upper surfaces level or even with the upper surface of the platform, and their point of contact in the middle of the hopper, or at the place where the fold or crease in the paper is required to be made. The two parts of the platform are hinged to the hopper, and operated by a cam

Digitized by Google

so as to alternately raise the paper clear of the rollers, and then lower it into contact with the rollers, which, having rotary motion, seize and draw the undermost sheet by its middle in betwixt them, folding or doubling it. As it emerges from these rollers it is conducted by tapes or other suitable guides to another platform, when it is pushed by a suitable instrument into contact with another pair of india-rubber rollers which draw it in betwixt them, as in the former case, folding or doubling it in another place, and as it emerges from them it is again conducted to another platform and pushed into contact with another pair of rollers between which it is drawn in like manner, as in the former cases, thus folding it a third time, and for any further number of folds required an additional platform and rollers may be employed.—Patent completed.

1537 C. E. BROOMAN. *Improvements in kilns or furnaces, particularly applicable for burning plaster of Paris.* (A communication.) Dated May 23, 1867.

The chief features of this invention are:—First, the distribution of the crude plaster or material in a state of powder upon two inclined surfaces heated by two fireplaces to commence the burning of the plaster. Second, the combination of the burning by the successive fall or descent of the plaster upon inclined surfaces, which are continued in a zig-zig manner to the bottom of the kiln, the said inclined surfaces being heated by a main fireplace at the bottom. Third, the escape of the steam or vapour from the plaster which is being burnt by tubes or passages in the side of the apparatus leading through the brickwork. Fourth, the continuous working of the kiln for burning crude plaster in powder. Fifth, the final fall of the burnt plaster into a receptacle formed underneath the apparatus.—Patent completed.

1538 T. G. GREEN. *Improvements in the manufacture of articles of earthenware.* Dated May 23, 1867.

The object of these improvements is to economize the production of articles made of earthenware by using an inferior or inexpensive body or material as the foundation or basis for a complete facing or covering of superior body or material, except where any portion of the body or basis may be desired to be exposed for ornamental effect, the same being most suitable for large pieces of ware requiring a considerable quantity of material for their construction.—Patent completed.

1539 A. V. NEWTON. *An improved feed-water arrangement for the tenders or water tanks of locomotive engines.* (A communication.) Dated May 23, 1867.

This invention consists of the employment of two branch pipes from the tender to the engine, by one of which steam can be blown in whilst water is being delivered by the other.—Patent abandoned.

1540 L. STUCKENSCHMIDT. *Improvements in the means of and apparatus for landing, trans-shipping, or discharging grain and other substances in or from ships, vessels, granaries, or warehouses, and for taking or drawing samples of grain from granaries.* Dated May 23, 1867.

According to this invention a travelling elevator is employed which is capable of being moved along the front of the wharf, granary, or warehouse, on rails provided for the purpose, so that the cargoes of barges or vessels that may be aground may be discharged and stored in the granary.—Patent completed.

1541 H. BLACKHAM. *Improvements in the manufaacture of spectacle frames.* Dated May 24, 1867.

This invention relates to D-eye or other side folding spectacle frame where a top eye is used in addition to the ordinary bottom eye, and consists in attaching the top eye to the bottom eye by means of a double joint, and in securing the springs to the top eye in any convenient manner, the object being to attach the spring to the top eye in a permanent manner, instead of pointing it to the bottom eye.—Patent abandoned.

1542 J. M. MUTERSE. *A process for extinguishing fires by means of cartridges composed of the most improper materials to combustion, diluted in water, for projecting on fire.* Dated May 24, 1867.

The principle of this invention is founded upon the extinguishing property of chloridric acid gas. The extinguishing cartridges are made with the residuum of salt pits or marshes.—Patent abandoned.

1543 C. MARTIN. *Improvements in railway buffers.* Dated May 24, 1867.

According to this invention the inventors arrange the buffers to act in pairs, one of the buffers being fixed to the buffer plank, and being formed with a recess into which the end of the spring buffer is received. The fixed buffer is bell-shaped, or the sides of the recess are so formed as to guide the end of the spring buffer into it, and towards the centre of such fixed buffer.—Patent abandoned.

1544 T. W. HELLIWELL. *Improvements in looms for weaving, and in apparatus connected therewith.* Dated May 24, 1867.

This invention cannot be described without reference to he drawings.—Patent completed.

1545 G. M. WELLS. *Improvements in apparatus to be employed in the manufacture of boots and shoes.* Dated May 24, 1867.

This invention relates to the sockets or holders and standards or supports employed for holding the lasts during the process of making and finishing boots and shoes, and has for its object affording facility for placing or adjusting the last in any convenient position required by the workman, and consists in mounting the standard which carries the last in a revolving socket, whereby the last is free to be rotated horizontally so as to bring any side in front of the workman.—Patent abandoned.

1546 L. SLATTER. *Improvements in cases for packing and transporting butter and other dairy produce.* Dated May 24, 1867.

For this purpose the inventor provides shallow cases on trays of wood or other material. The fronts of these cases are provided with rebates at each end taking into grooves in the sides of the case, from which they are easily lifted out at the time of tilling or emptying the cases.—Patent abandoned.

1547 A. M. CLARK. *Improvements in steam generators.* (A communication.) Dated May 24, 1867.

This invention consists in constructing the boiler entirely of tubes of such dimensions and calibre that the danger from explosion shall be determined at least fourfold when compared with the ordinary boilers now in use, and in arranging and combining the tubes in such a manner that the inventor can stop off or remove a defective ube with very little difficulty or delay, maintaining at the same time a perfect circulation of the water, and but slightly interfering with the efficiency of the boiler.—Patent completed.

1548 G. HOWARD. *Improvements in the construction of parquet flooring.* Dated May 24, 1867.

This invention consists in forming the foundation or backing the parquet or ornamental surface of the floor of any convenient or suitable number of layers of wood, arranged and combined as described.—Patent completed.

1549 C. SANDERSON. *Improvements in the manufacture or melting of cast steel.* Dated May 24, 1867.

The patentee claims the manufacture or melting of cast steel by first submitting the metal in crucibles to a preliminary heating, so as to bring it into a soft pasty state by the combustion of heated air and gases in a close space or chamber, and then completing the melting of the steel in a second furnace, in the manner described.—Patent completed.

1550 T. GREENWOOD. *Improvements in boring metals in the solid.* Dated May 24, 1867.

According to this invention the work to be drilled is mounted vertically above a tank containing lubricating material, and bored upwards from its lower end by fixed drills mounted in the tank.—Patent completed.

1551 G. T. BOUSFIELD. *Improvements in braiders or embroidering apparatus to be used with sewing machines.* (A communication.) Dated May 24, 1867.

This invention has for its object improvements in braiders or embroidering apparatus to be used with sewing machines when it is desired to employ the same for embroidering cloth or other fabrics or materials. For this purpose the apparatus is formed with a clamp by which it can be clamped to the presser bar, or other suitable part of a sewing machine. The clamp carries a plate or frame, to which is pivoted a vibrating arm, which hangs vertically, or nearly so, the pivot being placed intermediate of the length of the arm; in the lower end of the arm is an eye through which the embroidering thread or braid is led.—Patent abandoned.

1552 J. M. NAPIER. *Improvements in appliances for serving mustard.* Dated May 24, 1867.

This invention consists, essentially, in serving mustard by forcing it through an orifice, instead of with a spoon, as usual.—Patent completed.

1553 J. SIMPSON. *A new and improved arrangement of apparatus to be employed in producing photographic pictures.* Dated May 25, 1867.

This invention is designed for the purpose of facilitating the process of obtaining enlarged photographic pictures from small negatives, by the use, in connection with the ordinary camera of an elongated conical dark tube, which is connected with the camera so as to have the lens enclosed and embraced by the narrow end of the cone.—Patent abandoned.

1554 A. OLDROYD. *Improvements in the manufacture of tobacco and other pouches, part of such improvements being applicable to the frames of other bags or receptacles.* Dated May 25, 1867.

According to these improvements the patentee attaches or connects the india-rubber pouch to its frame by enclosing it in or covering it with the edges of the sheet rubber forming the pouch by means of india-rubber solution before it is cured or converted by chemical agency to render it permanently elastic. The second part of the improvements consist in forming india-rubber tobacco or other pouches (combined or made up with a hinged metal frame, as previously described, according to the first part of these improvements) with two separate pouches or receptacles, one of such pouches being attached to one part or half of the hinged metal frame, and the other to the other part or half of the metal frame employed for closing the opening to such pouches.—Patent completed.

1555 A. M. CLARK. *Improvements in the manufacture of what are termed watered fabrics, and in apparatus connected therewith.* (A communication.) Dated May 25, 1867.

This invention consists in producing a watered effect in fabrics by imparting a greater or less tension to certain threads, or groups of threads, during the weaving. The means employed for obtaining such result consist in imparting a variable tension to the warp threads divided into series on winders having different degrees of tension. Also in varying the beating at all points of the weft by means of a reed having teeth, which may be rendered rigid or deflected at will, such result being obtained, among other ways, by the aid of a roller provided with relief surfaces acting in each tooth of the reed, either direct, or by the aid of intermediate parts, all in the manner described, such effects varying according to the nature of the relief surface of the roller.—Patent completed.

1556 I. BAGGS and F. BRABY. *Improvements in the treatment and utilization of certain ferruginous and calcareous salts and solutions.* Dated May 25, 1867.

This invention relates to the treatment and application of the waste wash or liquor which results from the operation of cleansing iron by hydrochloric acid, for the purpose of depositing zinc and other metals thereon, ordinarily known as the "galvanizing" process. In order to neutralize the free acid which may remain in the wash or liquor, scrap iron may be digested therein, or the free acid may be neutralized by any convenient or suitable means. The wash or liquor should then be filtered or decanted, and upon the subsidence or separation of the impurities it should be boiled down to a moderate density for the convenience of carriage. The wash or liquor thus obtained and prepared contains a proportion of iron in the state of muriate or chloride, and may be employed for various manufacturing and useful purposes, and especially for the manufacture of muriate of ammonia from gas liqour, or other ammoniacal liquor or vapour, and which forms the subject of this invention, the muriate of iron, hitherto a comparatively waste and useless product, being thus employed and utilized instead of hydrochloric acid for the purpose of the formation and separation of muriate of ammonia from the gas liquor, or other ammoniacal liquor or vapour. The solution of muriate of iron is simply mixed with the gas or other ammoniacal liquor; the ammonia contained in the first-mentioned solution is converted into carbonate and sulphide of iron by means of chemical reactions, which are well understood. The iron salts, together with the tar contained in the gas or other ammoniacal liquor under treatment, should be allowed to subside, and be then separated by any of the well-known means. A solution of muriate of ammonia is thus obtained, which should be concentrated by means of heat, crystallized, roasted, and sublimed, as is well understood.—Patent completed.

1557 W. RYLAND. *An improvement or improvements in teapots, coffeepots, and other vessels.* Dated May 25, 1867.

The patentee claims forming under the sockets of the handles of the said vessels, or at the parts where the ends of the handles are connected to the vessels, air chambers projecting into the body of the vessel, and isolating the handles from the said sockets or hollow parts, substantially as described and illustrated, for the purpose of keeping the handles of the vessels cool during use.—Patent completed.

1558 W. DUTTON. *Improvements in constructing furnaces for heating salt pans, and for other purposes.* Dated May 25, 1867.

According to this invention, two sets of firebars are used in two fireboxes placed side by side, but with a flue space between them. At the back of the fireboxes are side openings into this flue space, which space is divided by a horizontal partition into two parts, communicating at the front. The products of combustion from both fireboxes pass in common into the flue space between the fireboxes, and then along the upper part thereof to the front; they then descend to the under side of the partition, and pass again to the back, and under the bottom of the pan. The pan also forms the top of the fireboxes and of the flue space between them.—Patent completed.

1559 W. P. STRUVE. *Improvements in furnaces for calcining copper ores, and other ores and metals.* Dated May 25, 1867.

This improved furnace consists of four containing walls enclosing a space, two horizontal partitions passing across this space form a chamber within it in which the ore or metal to be roasted is placed. There is a fireplace at one end of the furnace, and the heated products of combustion from the fire pass by passages from the fireplace into flues over and under the chamber. These flues are enclosed at the top and bottom respectively by other horizontal partitions, and the heated products having travelled to the further end descend into return flues at the bottom of the furnace chamber, and so pass into an underground passage leading to the chimney. The roasting chamber, thus, does not communicate with the flues; there may, however, be an opening from the one to the other provided with a valve or damper.—Patent completed.

1560 H. B. BARLOW. *Improvements in apparatus for coupling pipes.* (A communication.) Dated May 27, 1867.

This improved apparatus is applicable in coupling steam, gas, water, and other pipes, having a socket at one end into which the end of another pipe fits. This apparatus consists of four, or other convenient number, of segments, connected together by a hoop; one end of the segments is recessed to fit on the socket of the pipes to be coupled, and to the inside of each segment is screwed a thin steel blade, and these blades are surrounded by a ring or hoop of india-rubber or other packing. The apparatus having been placed on the socket of the pipe, the end of the pipe to be coupled is forced within the blades of steel, thereby expanding them and the packing ring inside the socket; the hoop is then knocked off the segments, and the segments with the blades of steel are drawn out of the socket, leaving the packing ring in its place. By this apparatus pipes can be coupled very expeditiously, and the packing ring is sure to be left in its proper place within the socket.—Patent completed.

1561 H. FROST, sen., and H. FROST, jun. *Improvements in apparatus for measuring fluids, which improvements are also applicable for obtaining motive power, and for pumping.* Dated May 27, 1867.

This invention cannot be described apart from the drawings.—Patent completed.

1562 W. P. METCHIN. *Improvements for taking copies of lithographs, zincographs, and other printed matters.* Dated May 27, 1867.

The inventor proposes to employ a powder composed of nutgalls, logwood, or any other woody substance containing tannin, with sulphate of iron and gum mixed in certain proportions. He then distributes this powder over the surface of the printed matter, which remains on the surface without mixing with the oily substance of the printing-ink. Having done this, a correct copy may be taken by applying a damp sheet of copying paper over the printed matter, and pressing it in the ordinary way in a copying press.—Patent abandoned.

1563 W. AFFLECK. *A new or improved tyre or guard for wheels of reaping, mowing, and other machines.* Dated May 27, 1867.

The patentee claims the construction and employment of a loose tyre or guard for fitting over the wheel or wheels of reaping, mowing, and other machines, substantially as described, and illustrated in the drawings.—Patent completed.

1564 R. R. KNOTT and J. JEYES. *An improvement in preparing wood and adapting it as a substitute for leather.* Dated May 27, 1867.

This invention consists in cutting wood into thin layers, so that it shall be yielding without breaking, and then placing one or more layers together, and securing them together by means of an elastic cement.—Patent abandoned.

1565 P. A. J. DUJARDIN. *Improvements in electric telegraphs.* Dated May 27, 1867.

This invention cannot be described apart from the drawings.—Patent completed.

1568 J. C. MEWBURN. *Improvements in harvesting machines.* (A communication.) Dated May 27, 1867.

This invention consists, first, in combining with a main frame balanced upon two supporting and driving wheels, and having a rigid tongue projecting from its forward end, and a driver's seat mounted upon the rear end, a supplementary frame hinged at its forward end to the main frame in advance of the main axle, and in line with the countershaft, and having the cutting apparatus hinged to the rear end of the supplementary frame in such manner as to have both a rising and falling and an axial movement independent of the main frame. Second, in combining with a supplementary frame, hinged as described, a finger beam pivoted at the heel of the shoe to the inner rear corner of the supplementary frame by a swivcling joint, and at the front of the shoe to a pivoted coupling arm passing over the supplementary frame, and secured to the outer side thereof, and a rocking lever pivoted to the supplementary frame and coupling arm to rock the finger beam axially. Third, in a lever which serves both to lock the finger beam, and to raise it horizontally, or parallel to the ground. Fourth, in combining with the

Digitized by Google

hinged finger beam a rocking lever to rock the beam axially, and a lifting and locking lever which raises the beam horizontally. Fifth, in a novel mode of connecting the finger beam to the frame. Sixth, in a swiveling pitman box..—Patent abandoned.

1569 H. PETHER. *Producing by a new method ornamental bricks for building purposes.* Dated May 28, 1867.

This invention refers to a means of imparting to the faces of bricks a diaper or ornamental pattern, by the following means:—Upon a metallic table is affixed a vertical frame, the inner edges of which are prepared to receive and guide an ascending and descending horizontal frame, which, acting on wedges attached to the sides of a metallic box hinged and secured at the bottom, causes the same to collapse when this horizontal frame ascends, and resume their open or spread position on its descent. Into this box is placed in a firm state the clay intended to form the brick.—Patent completed.

1571 E. T. HUGHES. *A combined seeder, cultivator, and roller.* (A communication.) Dated May 28, 1867.

This invention cannot be described apart from the drawings.—Patent completed.

1572 G. H. J. SIMMONS. *A lamp for burning hydrocarbon oils (explosive or non-explosive, without danger), permitting the same to be replenished without extinguishing the flames of the burner or burners, also without danger, the receptacle containing the oil to be so closed as to prevent evaporation, or the escape of noxious vapours, the position of the receptacle containing the oil so arranged as to prevent any unnecessary shadow.* Dated May 28, 1867.

In performing this invention the inventor employs a receptacle having but one opening at its base for the entrance and exit of the oil; fastened over such opening is a dome of wire gauze; attached into the receptacle are two tubes of unequal length; attached to the shorter tube is a stop-cock to allow of the removal of the receptacle when containing oil without its spilling; the other end of the tubes are inserted into a small chamber; the ends of the tubes screwed into the receptacle containing the oil are level with each other, but the ends attached to the small chamber are not level, the effect of which is that the oil flows from the opening of the longer tube until it reaches the opening of the shorter tube, thereby preventing the admittance of the atmosphere.—Patent abandoned.

1573 F. J. VANDENVINNE. *An improved machine or plough for clearing or grubbing up uncultivated land.* Dated May 28, 1867.

This invention consists in an improved construction of machine for tilling or ploughing uncultivated land to a great depth, and also for the execution of all kinds of open earthwork, such as cuttings for railroads and canals. This is effected by forcing forward a framework carrying two vertical driven shafts in front of it; each shaft is armed with a series of picks stacked firmly on it, and so placed that the series on the two shafts intersect each other, and thus cut away the ground as the machine advances; if for tilling only, the earth is left as the picks leave it, but if a pass or cutting is to be made, the earth is excavated and thrown aside by elevators.—Patent completed.

1574 W. COULSON. *Improvements in the doors and door-frames of furnaces.* Dated May 28, 1867.

This invention consists in making the doors and door frames of furnaces hollow and water-tight, and causing water to circulate through the same. Firstly, in order to keep the doors cool, and prevent or diminish the action of the fire on the metal; and, secondly, to keep the engine and boiler-rooms cool in steamships, and to obtain from the waste heat thus absorbed a supply of heated water for feeding the boiler, or for other useful purposes.—Patent completed.

1578 H. and F. C. COCKRY. *Improvements in seal or dip pipes in combination with gas and other retorts.* Dated May 28, 1867.

The patentees claim, first, the constructing and arranging of the seal or dip pipes used in connection with gas and other retorts in such a manner as that they may be readily sealed before the opening of the retort, and unsealed after the retort is closed, for the purpose described. Second, the making of the seal or dip pipes used in connection with gas and other retorts telescopic, so as to be capable of being sealed or unsealed as required, by lowering or elevating them by a lever or otherwise, as described.—Patent completed.

1579 T. F. CASHIN. *A compound lever (or combination of levers) for working railway points and signals, and for all other purposes to which it may be applicable.* Dated May 28, 1867.

This invention consists in the combination of two levers whereby points or signals, or a set of points and signals of railways, can be actuated and locked in the position required, the points open or closed, and the signals up or down, by the direct action of the levers.—Patent abandoned.

1580 W. MITCHELL. *An improved food for sheep and other animals.* Dated May 28, 1867.

The patentee claims the use of the seed or pulse of the lupin, combined with linseed or other seed or grain or pulse, as food for sheep and other animals.—Patent completed.

1581 L. H. DETHIOU and F. BEAUBRY. *An improved tongless buckle with continuous pressure.* Dated May 28, 1867.

The object of the present invention is to do away with the tongue of the buckle, substituting in its place a spring pressing on an inclined plane; the spring is strengthened on one side by a frame bearing the plane, and is furnished with elbows or projections acting as stops for preventing the overstraining of the spring whilst inserting the belt or band between it and the inclined plane.—Patent completed.

1582 A. M. CLARK. *Improvements in machines for washing and bleaching cloths and all kinds of textile materials.* (A communication.) Dated May 28, 1867.

The patentee claims the improved washing, bleaching, and rinsing apparatus described and represented in the drawings, the chief features being the employment of one or more clasher plates, nets, rods, or other means of supporting the linen, which is alternately raised from and lowered in the of liquid, in the manner and for the purpose described.—Patent completed.

1583 D. TUNKS. *Improvements in galvanometers for receiving signals through submarine and other electric telegraph lines, and for testing them.* Dated May 29, 1867.

The object of the invention is to provide an instrument for use as a galvanometer that is of extreme delicacy, and not liable to be easily put out of order. An instrument which contains all the improvements that are comprised in this invention consists of an electro-dynamic coil in two halves, and having its axis horizontal. Each half is a complete coil, and the two halves are juxtaposed laterally so as to act as one coil upon a horizontal magnetic needle, which is mounted upon a vertical axis that passes freely through the division between the coils. The said vertical axis is mounted in jewel holes that are suitably placed on cocks which rise from the same foundation plate that carries the coil, the lower cock passing into the interior of the coil, and the upper cock projecting over the top of the coil. A horizontal graduated dial plate, and a pointer of aluminium, enable the motions of the needle from its normal position (parallel to the wire coils) to be noted, or its deflections to be observed. The electric current is conveyed to the coil by means of binding screws connected with its terminates, and placed upon the base plate or foundation plate of the instrument. A peculiarity of the invention consists in the use of a pendulum or hair spring in connection with the said vertical axis, and thereby accomplishing two desirable objects. First, the neutralization of the gravity of the vertical axis and its appendages; and, second, it affords the utmost facility to neutralize the directive influence of the earth's magnetism upon the magnetic needle, and thus enables it to move freely upon the slightest impulse.—Patent abandoned.

1584 R. POLLIT. *Improvements in steam boilers and the method of construction of the same.* Dated May 29, 1867.

This invention relates to a former patent granted to the present patentee, dated July 9th, 1860, and consists in the application or addition of "water tubes" to the back internal "elbow flue" of the boiler, for the purpose of obtaining a greater amount of heating surface. These tubes the patentee makes of any suitable section, as circular or oval, and fixes them in the said flue or flues in a vertical, diagonal, or suitable angular position, the ends of the tubes being open to the water space, and the body of the tubes being exposed to the products of combustion passing through the flue. The method of construction of the said "elbow" flue, as adapted to the application and attachment of the "water tubes," is also applicable to other forms of boiler than the one herein above referred to, and is as follows, namely, from about the centre of the plate which is to form one "ring" of the flue, a piece is cut out of a size and form suitable to the cross section of the water tube, and from each end of the plate a piece is out out of a form and size suitable to form a corresponding opening to the one in the centre of the plate. When the plate is bent into a ring or cylinder, and the edges or ends of the plate on each side of the opening are welded together, suitable rivet holes are formed around the openings for the attachment of the water tube in position, and a template is temporarily fixed by means of the rivet holes near the joint for the purpose of maintaining the form of the "ring," and the relative positions of the ends during the operation of the welding. This method of construction enables the patentee to obtain a sound weld, owing to the portion to be welded at each operation being comparatively short.—Patent completed.

1585 W. J. BURGESS. *Improvements in the construction of fingers for mowing machines.* Dated May 29, 1867.

This invention relates to the fingers of the cutting apparatus of mowing machines, and consists in forming the point of each finger of wrought metal, and the other parts of cast metal.—Patent completed.

1586 J. F. N. B. SIMONS. *Improvements in preventing the incrustation of steam boilers.* Dated May 29, 1867.

This invention consists in introducing into boilers several cakes of moulded charcoal, or what is called in France "charbon de Paris," on which incrustation is supposed to take place instead of on the plates.—Patent completed.

1587 C. MINASI. *Improvements in musical wind instruments, called trombomettes.* Dated May 29, 1867.

The inventor divides his invention into six parts; for perusal of which see his patent, which is not proceeded with.

1588 T. MITCHELL. *Certain improvements in the manufacture of felt carpeting.* Dated May 29, 1867.

This invention consists in so preparing the selvages or sides of the "lap" as it comes from the "batt frame" or the piece in its hardened state, and in so attaching them together by yarns or threads, or by gum or other adhesive matter, and submitting the whole fabric after being thus prepared to a subsequent process of "milling up;" that, when completed, the fabric shall present an appearance, and be almost as even and quite as durable as if felted in one width.—Patent completed.

1589 F. J. BREAN. *Improvements in producing letters in gold, silver, and other metals, on glass, and in implements employed for that purpose.* Dated May 29, 1867.

In performing this invention the patentee constructs type or stencil plates of thin metal or other suitable material, and of the form of the letters to be produced, which type, after the surface of the glass has been coated with gold, silver, or other thin metal leaf, are placed upon such coated surface in positions corresponding with those in which it is desired to produce the letters on the glass. The type being held securely in these positions by certain special means, the metal on the glass surrounding each letter is brushed off by means of a brush, thus leaving the metal beneath the type in the form of the required letters, which have perfectly sharp edges, and merely require to be trimmed off at the top and bottom after the type has been removed.—Patent completed.

1590 J. R. COOPER. *Improvements in cartridges for breech-loading firearms.* (Partly a communication.) Dated May 29, 1867.

The patentee claims fixing at the base of the said cartridges, and immediately behind a cap or disc containing the fulminate or detonating powder, a disc of india-rubber, or other elastic substance, through which elastic disc the needle of the gun passes to ignite the fulminate, and which elastic disc, on the explosion of the cartridge, is expanded laterally and made to close the chamber of the gun, and prevent the escape of gas at the breech, substantially as described.—Patent completed.

1591 J. M. FRENCH. *Improvements in instruments or apparatus for measuring spirits and other liquids.* Dated May 29, 1867.

The object of this invention is to permit of the rapid drawing off of measured quantities of liquid from a barrel or reservoir. The inventor describes his invention as being a measuring vessel placed between full and empty casks. Through the axis of this measuring vessel passes a stop-cock plug, which admits the liquid to the measuring vessel by one quarter turn, and lets it off by a further quarter turn.—Patent abandoned.

1592 R. NEWTON. *Improvements in the furnace apparatus of steam boilers.* Dated May 29, 1867.

This invention consists of an endless band of transverse fire bars caused to revolve slowly, carrying the fuel in with them. These bars are supported in the boiler flue by three ribs, one central and one at each side.—Patent abandoned

1594 T. E. PASSEE. *An improved mode of obtaining motive power, and the apparatus employed therein.* Dated May 29, 1867.

This invention consists in a method of procuring perfect vacua, or nearly perfect vacua, in cylinders of any given diameter, and of given volume or content, by pistons moving and fitting air-tight and freely within them, and in the application to an unlimited extent of the vacuum motive principle, either by one, less than one, or more atmospheres, or any other suitable pressure, to produce rectilinear action, which, adjusted with other auxiliary cylinders to alternate or reciprocate by spring, lever, beam, rotary axis, and other mechanical contrivances, and then started, results in continuous movement till stopped by failure of the vacua or other causes of derangement.—Patent completed.

1595 W. B. RITCHIE and J. G. WILLANS. *Improvements in drying peat and other materials.* Dated May 29, 1868.

The patentees claim drying peat, either alone or mixed with other materials, by means of vertical currents of air heated by waste products of blast or puddling furnaces in which peat is used; also, the formation of blocks of granulated iron ore and peat.—Patent completed.

1596 H. TURNER. *Improvements in marine and other steam engines on the high and low pressure compound principle.* Dated May 29, 1867.

This invention relates to an improved construction and arrangement of parts of engines on the high and low pressure compound principle, and has for its object the introduction of connecting links or rods to the shafts of high and low pressure marine and other engines working expansively, so as to obtain a short and direct passage across the high pressure to the low pressure cylinders, these cylinders being placed side by side. By the use of these links and rods, also, a well balanced engine is obtained, without the necessity of resorting to the use of heavy weights, as is now done, and the engine generally occupies less space than other engines on the same principle, while steam is also greatly economized.—Patent completed.

1597 E. JONES. *Improvements in the construction of safety lamps for miners.* Dated May 29, 1867.

This invention is not described apart from the drawings.—Patent completed.

1598 A. V. NEWTON. *An improved method of producing mosaic veneers.* (A communication.) Dated May 29, 1867.

This invention relates to the production of mosaic veneers or surfaces in an economical and expeditious manner, and consists, first, in forming prismatoidal rods of suitable form and colour for producing, when put together side by side, a surface with the required design by forcing through apertures of the form of the cross section of the intended rods a plastic material, which, after the rods have been formed, will become, or which may be rendered, of sufficient hardness to be used as a veneer. And, second, in uniting such strips so formed into blocks the cross section of which will be of the form of the surface to be veneered, or of a section thereof.—Patent completed.

1599 W. E. NEWTON. *An improved mode of producing printing blocks or surfaces for printing or staining various fabrics.* (A communication.) Dated May 29, 1867.

The patentee claims preparing electrotype printing blocks for printing fibrous and textile fabrics by means of a mould formed of different lengths of type (as represented in the drawings), so as to have a highly raised printing face composed of metal margins surrounding a felt or other equivalent soft or plastic substance to lift and carry the colour, substantially as described and illustrated in the drawings.—Patent completed.

1600 T. GREENWOOD. *Improvements in the construction of milling machines.* Dated May 29, 1867.

According to this invention the patentee forms in the bed of the machine, immediately below the spindle, vertical guides to receive a sliding block on which is mounted the slide for carrying the work, and by means of a vertical screw which enters a tapped hole in the bottom of the vertical sliding block he raises or depresses the block, as required, to any given distance within its range, without imparting any unsteadiness to the block.—Patent completed.

1601 H. OAKES. *Improvements in the manufacture of ear rings.* Dated May 29, 1867.

This invention consists in manufacturing earrings without the usual accompaniment of ring or hook, thus obviating any necessity for the ears to be pierced. This the inventor effects by connecting above the pendant a contrivance consisting of a pair of miniature jaws or clips, having a pincer or plier action.—Patent abandoned.

1602 H. BAIN. *Improvements in dyeing yarns, and in the machinery or apparatus employed therefor.* Dated May 30, 1867.

This invention consists, essentially, in a new or improved mode of dyeing yarns in banks, by giving them a slow motion in the direction of their loops or threads, while at the same time they are traversed in sets, also at a slow rate, horizontally immersed for a great portion of their length in the liquids or dyes employed in their treatment, placed within a suitable cistern for the purpose.—Patent abandoned.

1603 C. E. BROOMAN. *Improvements in photographic albums and other like articles.* (A communication.) Dated May 30, 1867.

This invention consists in the employment of movable name cards or slips, and in the formation of a sort of chamber or receptacle in the leaf or passe partout into which these name cards can be readily inserted.—Patent completed.

1604 J. FRANCOMBE. *A new or improved engine or machine for obtaining and applying motive power.* Dated May 30, 1867.

This invention essentially consists in the construction of engines or machines for obtaining and applying motive power wherein the piston is a fixture and the cylinder is movable. According to one arrangement the cylinder is suspended from a cross shaft resting on bearings in a frame, and free to oscillate thereon, the frame uniting the shaft to the cylinder acting as a pendulum.—Patent abandoned.

Digitized by Google

1605 W. ORR. *Improvements in machinery or apparatus for separating liquids or moisture from substances, and also for rectifying and cooling animal charcoal and other substances, and for treating sugar.* Dated May 30, 1867.

The great length of this specification precludes our quoting it here at sufficient length for an intelligible abstract.—Patent abandoned.

1606 J. ASTBURY. *Improvements in casting Bessemer metal, steel, and other metals.* Dated May 30, 1867.

This invention is intended to avoid the chilling and honey-combing arising from and in the present mode of casting. For this purpose the patentee casts the metal to produce the ingot or other form into a mould which is heated in a furnace sufficiently to prevent the metal solidifying, and then he gradually cools the lower part of the mould whilst the heat is still maintained at the upper part of the mould, the cooling and setting of the metal taking place progressively from the bottom of the mould upwards, and then, as contraction takes place, fluid metal descending from the upper part of the mould prevents the formation of cavities in the casting.—Patent completed.

1607 W. WOOD. *Improvements in the manufacture of printed tapestry carpets.* Dated May 30, 1867.

The object of this invention is to make the carpet thicker, softer, more elastic and warm, and consists in making the dead warp wholly or partly of certain other materials in suitable forms and combinations. First, the patentee makes the dead warp of yarns composed wholly or partly of silk obtained from cuttings and rags of woven fabrics wholly or partly of silk, which he tears up, and either alone or combined with any other suitable fibres, forms by the usual or other convenient processes into yarns of suitable size and strength. Second, he forms the dead warp of yarns made wholly or partly of wool, hair, or such like animal fibres, either new or obtained from cuttings and rags of woollen, union, or linsey fabrics, and spun waste, and new or old carpeting; these, also, either alone or mixed with other fibres, he forms by the usual or other convenient processes into yarns of suitable size and strength.—Patent completed.

1608 W. E. NEWTON. *Improvements in the treatment of fabrics made wholly or partly of jute, flax, cotton, or vegetable fibres, so as to prepare them for dyeing or printing, and rendering them applicable for the manufacture of carpets or other printed goods.* (A communication.) Dated May 30, 1867.

This invention is carried out in the following manner:—The cloth after being woven from the raw jute, flax, or cotton in the ordinary manner, is immersed in a bath of water at, say, from 90deg. to 120deg. Fah., in which has been mixed a quantity of either wheat or corn bran, together with sub or bi-carbonate of soda. After remaining in this bath for a sufficient length of time to thoroughly dissolve the tannin in the jute or cotton, or the gluten or gum in the flax, the cloth must be removed and washed thoroughly in clean water. It is then to be immersed in a bath of cold water mixed with a solution of crystallized tin and muriatic acid, or strong muriate of tin with 20 per cent. of oil of vitriol or sulphuric acid, at a strength of from 1deg. to 2deg. Twaddel. When the cloth has been impregnated with this bath, it is to be again washed in clean water, and then submitted to a bath of a weak solution of chloride of lime, after which the cloth is to be washed clean and dried, and it will then be ready for printing or dyeing.—Patent completed.

1609 W. E. NEWTON. *Improvements in the manufacture of felted fabrics.* (A communication.) Dated May 30, 1867.

The patentee claims manufacturing felted fabrics with a velvet plush or napped surface in the manner set forth. He claims particularly producing the napped surface on felted fabrics by teazling the surface or fabric before the felting operation is completed, and then subsequently felting the fabric again in order to obtain the required texture, as set forth.—Patent completed.

1610 T. PETITJEAN. *A new means for procuring the more perfect combustion in the burning of fuel.* Dated May 30, 1867.

The patentee claims, first, the method of converting solid fuel into inflammable gases after having made use of it, that is, by the waste heat of the products of combustion only, when they carry out 60 per cent. of the heat developed in the burning of fuel. Second, the division of the total heat produced by fuel into heat of combination and heat of condensation, the latter forming the latent heat of the gases left after carbonic acid and water have been decomposed. Third, this division in heat of combination and heat of condensation giving a clear insight of the phenomena accompanying the conversion of carbonic acid and water into inflammable gases permits the laying down of rules to regulate the good working of the reproducer by fixing the temperature of its top and bottom, also the quantity of fuel it must contain, and, consequently, its exact dimensions. Fourth, the principle of a great fractional division for the use of the gas fuel which gives an easy control over the proper proportions of air and inflammable material, and secures their perfect mingling.—Patent completed.

1611 M. A. F. MENNONS. *Improvements in the construction of magneto-electric batteries.* (A communication.) Dated May 30, 1867.

This invention relates to improvements introduced into the construction of magneto-electro batteries with a view to obtaining by a slow motion of the armatures any required quantity or intensity of electric fluid. The improved battery may be constructed of different circles of bar magnets set partly around and partly above each other with corresponding intermediate armatures mounted on wooden or other suitable discs on a central shaft.—Patent completed.

1612 W. R. LAKE. *Improvements in breech-loading fire-arms.* (A communication.) Dated May 30, 1867.

This invention relates more especially to the conversion of muzzle-loading muskets and rifles into breech-loaders, which is effected in the following manner:—The rear upper part of the barrel is first cut away to form an opening or chamber for the breech-block. This block consists of a solid piece which fills up the said opening, as well as the bore of the barrel, and is hinged at its front end to a piece firmly attached to the barrel over the rear end of the same.—Patent abandoned.

1613 F. J. DEMANET. *An apparatus for the purpose of giving sufficient draught to any kind of chimney.* Dated May 31, 1867.

This apparatus consists of a square or other shaped chimney or body made of metal or other material, and surmounted by a cap formed of two vertical sides joined by an arched top, the cap being open at the ends. The said two sides are longer than the diameter of the chimney, and thus project beyond its exterior surface. One of the said vertical sides is curved concentric with the chimney, while the other vertical side is half straight and half curved eccentric to the chimney. The cap may have an opening in the top covered by an inclined plate to keep out the rain.—Patent abandoned.

1614 J. SCOTT. *Improvements in apparatus and in the means employed for subduing and extinguishing fires, partly applicable to other useful purposes.* Dated May 31, 1867.

This invention is not described apart from the drawings.—Patent completed.

1615 B. and W. SHAKESPEARE. *Improvements in reverberatory furnaces used for puddling, melting, and heating iron, and for other purposes.* Dated May 31, 1867.

The invention, with reference to a puddling furnace, is carried out as follows:—In a puddling furnace, as ordinarily constructed, the firegrate is placed at one end of the furnace, and the flame, after passing along the arch of the furnace, and over the iron contained on the bed of the furnace, passes to a flue at the end of the furnace opposite to that at which the fireplace is situated. In constructing a puddling furnace according to this inve tion the inventors build a firegrate at each end of the furnace, and they make a flue at about the middle of one side of the back of the furnace, by means of which flue the heated air and products of combustion are conducted to the stack or chimney, which may be placed near to the said flue. The flame from the fires on the said firegrates passes from either end of the arch and over the bed of the furnace, and meeting at the middle of the furnace passes by the flue described to the stack or chimney.—Patent abandoned.

1616 J. and J. HINKS. *Improvements in lamps for burning petroleum oil and other volatile liquid hydrocarbons.* Dated May 31, 1867.

This invention consists, first, in constructing and arranging the holders or galleries by which the shades of the said lamps are supported in the following manner:—The patentees take an ordinary flat wick burner, and place the shade holder or gallery at the bottom, or at the mouth of the said burner, instead of placing the said shade holder immediately below the cone or deflector of the burner. They make the said shade holder immediately below the cone or deflector of the burner, and of about 4in. in diameter, instead of 3in., as is usual, and they pierce in the said shade holder a series of small holes for supplying air to the flame, in place of cutting away about half or two-thirds of the metal of the holder, as is usual. In the shade holder they make a series of indentations or depressions in which they insert pieces of bone, wood, or other imperfect conductor of heat, the said non-conducting pieces projecting somewhat above the plane of the bottom of the shade holder. Upon the projections thus formed they place a disc of wire gauze or perforated metal, and thereby make a chamber through which the air has to pass before it reaches the flame. Upon this disc the shade rests, instead of upon the shade holder itself. By these means the currents of air produced by the punkahs or otherwise are prevented from acting upon the flame and causing the lamp to smoke, while the shade holder is isolated by the non-conducting pieces described from the shade, and thereby prevented from being heated by the said shade, and the punkah at the top of the said shade. The oil in the reservoir is thus kept cool. The invention consists, second, of a conical chimney, either circular or elliptical in cross section, to be used in place of the ordinary bulged shouldered chimney. The said chimney tapers from nearly the middle towards each end. By the use of a chimney of this kind, a free egress of the heated air combined with an equal expansion of every part of the chimney by heat are obtained, and hence the chimney is less liable to break than the ordinary bulged chimney. The invention consists, third, of the following improvements in punkah protectors for liquid hydrocarbon lamps. Punkah protectors are ordinarily made of wire gauze, or perforated metal, the said protectors having a conical figure, and being surmounted by a plain metal disc or a metal crinkle. In constructing the said protectors according to this invention the patentees make them of wire gauze or perforated metal, the tapering of the said protectors being greater than usual, that is, they make the base of the protector about 4in. in diameter, and the summit about 2in., instead of 3in. as usual. They surmount the protector by a cap or cover of a dome shape, the said cap being perforated at top and bottom, the perforations in the top being much larger than those in the bottom. Across the middle of the cap or cover they fix a disc or diaphragm of wire gauze or perforated metal.—Patent completed.

1617 F. W. DOLMAN. *Obtaining an essential oil applicable as a curative agent or medicine in the treatment of inflammatory joint diseases, rheumatism, sprains, bruises, and similar ailments.* (A communication.) Dated May 31, 1867.

This preparation is an oil obtained by distillation from a plant or grass called by the natives of India "Koos," also "Hurdwaree Koos," and is the sacred grass of the Hindoos. The botanical name of the said plant is Poa cynosuriolides.—Patent abandoned.

1618 J. LE BUTT. *Improvements in hay-making machines.* Dated May 31, 1867.

This invention relates especially to the construction of the frame of the machine, and to the means by which the inclination of the shafts to the frame may be adjusted, so as to vary the distance of the teeth from the ground. The sides and ends of the frame, in place of being in separate parts, as is usual, are formed of one bar of iron bent round; and to it, at the front, brackets are fixed to receive the shafts. The shafts are fixed upon a metal tube which enters between the brackets, and a bolt passing through it from end to end, and also through the brackets, secures the shafts, but they are free to turn upon the bolt.—Patent abandoned.

1619 T. PORTER. *Improvements in apparatus for supporting or holding music and other books, and for turning over the leaves of the same.* Dated May 31, 1867.

According to this invention the inventor supports the book, and holds it in its proper position, by the aid of a contrivance which is inserted into the middle of the desk at the lower part or supporting ledge thereof. This consists of two parallel pins connected together at one end by a cross piece, to which cross piece, and between the two parallel pins, he attaches (at right angles to the pins) an upright arm, which lies in the fold of the book when properly placed, and thus keeps the book in position on the desk laterally. To one or both of the two parallel pins there is secured a spring nick, and in the front of the desk two holes are made into which the pins are inserted, one or both of such holes being slightly oblong to admit the spring rack or racks as well as the pin.—Patent abandoned.

1620 JAMES EARL OF CAITHNESS. *Improvements in ships' compasses.* Dated May 31, 1867.

This invention relates to a mode of suspending ships' compasses with a view to prevent undue oscillation in heavy seas, and consists, essentially, in attaching to the compass box or case containing the card or needle a weighted rod or pendulum, which is allowed to swing freely by a ball and socket joint situate as close as possible to the compass. The socket for the ball is contained in the upper part of a "binnacle" or other convenient frame or support, which will allow of the free play or swing of the pendulum. The bob or weight of the pendulum is made adjustable along the rod by a set screw, or other convenient contrivance, so as to admit of alteration or adjustment. By this contrivance the compass is constantly maintained in a horizontal position, as whatever may be the motion of the ship, the pendulum will always remain perpendicular.—Patent completed.

1621 R. REECE. *An improved mode of, and apparatus for producing cold.* Dated May 31, 1867.

This invention consists, chiefly, in the peculiar construction and arrangement of apparatus for effecting the continuous distillation and rectification of dilute solution of ammonia upon what is known as the separative principle, and in the combination with the said apparatus of a condenser and refrigerator. The ammoniacal gas is reduced by its own pressure to a liquid condition in the said condenser, from which it passes into the refrigerator, and having a very low temperature, quickly abstracts the heat from any fluid passed through the latter.—Patent completed.

1622 J. LANCELOTT. *Improvements in the manufacture of ornamental chains and bands.* Dated May 31, 1867.

This invention is not described apart from the drawings.—Patent completed.

1623 P. LAWRENCE. *Improvements in apparatus for applying adhesive agents to pieces of paper and other light materials, and for lifting the same, especially applicable to machinery for the manufacture of envelopes.* Dated May 31, 1867.

This invention consists of an improved construction of apparatus in which a holder or vessel for containing an adhesive agent receives reciprocating up and down motion, and carries with it in its travel contrivances with which it is furnished, and which are so actuated as to effect and interrupt as required the emission of the adhesive agent which such vessel or holder contains, and which adhesive agent when emitted is, by the action or travel of such holder or vessel, brought into contact with the pieces of paper or other material to which it is to be applied, and is applied to the same thereby, causing the same to adhere to the vessel or holder, and to be raised by and with it in its upward travel. In one arrangement for the purpose the vessel or holder which has outlets at bottom is fitted with a piston or plunger, or a stem carrying a valve for opening and closing such outlets; such piston, plunger, or valve is raised by means of an adjustable abutment at the upward motion of the vessel, so as to open the outlets, and is depressed when released from the action of such abutment so as to expel the adhesive agent and close the outlets.—Patent completed.

1624 A. M. CLARK. *Improvements in apparatus for applying and regulating motive power.* (A communication.) Dated May 31, 1867.

This invention is not described apart from the drawings.—Patent completed.

1625 T. POULTNEY. *Improvements in the construction of revolving fire-arms.* Dated June 1, 1867.

This invention is not described apart from the drawings.—Patent completed.

1626 T. POULTNEY. *Improvements in breech-loading fire-arms.* Dated June 1, 1867.

This invention relates to that description of arm in which the movable block for closing the breech is hinged or attached either permanently or temporarily to the rear end of the barrel, in such a manner as to admit of it being turned back in order to open the breech for the reception of a cartridge. In this description of firearms the movable breech block when in place lies snugly in a recess formed either by cutting down the upper half of the rear end of the barrel, or by screwing on a piece of the required size and form. It has been found that with this description of arm, as ordinarily constructed, some little difficulty is experienced in inserting the cartridge in consequence of the projecting vertical sides of this recess. The present invention has for one of its objects to obviate this inconvenience, and this is effected by cross cutting down the sides of the recess, and turning the part down into a horizontal position on the wooden stock, thereby giving more easy access to the open breech, not only without weakening the arm, but actually strengthening this part of the arm. Either one or both may be turned down in this manner.—Patent completed.

1627 W. BRADFORD. *An improved combination of wood and textile substance for the construction of boats, baths, and other vessels to be folded up for carriage.* Dated June 1, 1867.

The inventor takes thin slips of wood and attaches them firmly to cloth or textile material, so that their edges are close where a curve is required, and are further apart where a sharper angle is to be formed. The slips are flat, and the whole can be rolled up or folded for carriage. Or when the edges are bent and confined by suitable bars, strings, or bolts, the whole may be made to form a boat or bath, or other vessel, according to the various forms of the slips, and the relative positions of their edges and ends.—Patent abandoned.

1628 A. G. SCHAEFFER. *Improvements in obtaining increased light in the combustion of illuminating matters.* Dated June 1, 1867.

This invention consists in effecting approximation of incandescent atoms, or clusters of atoms, by the approximation or coalescence of two or more flames containing these atoms, and in such manner as to obtain the most close possible approximation of the heated atoms in one flame to the heated atoms in another flame (but not so as to cause gases), to emit before ignition. Patent abandoned.

1629 F. B. HOUGHTON. *Improvements in steam boilers and in superheating pipes.* Dated June 1, 1867.

This improved boiler is fitted with a coil of pipes which is kept full of water, and the novelty consists in employing such pipes of a larger diameter than have heretofore been used, and in a different arrangement of them.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated September 3, 1867.

2492 A. E. Gelhaye, Windmill-road, Croydon, engineer. Improvements in machines for manufacturing chains, cords, ropes, and the manner of making such chains, cords, and ropes.

Dated November 23, 1867.

3318 P. Salmon, Great Smith-street, Westminster, engineer. Improvements in the manufacture of gas, and in the treatment and application of such and other gases for cooking, warming, lighting, generating of steam, and other purposes, combined with their use as a motive power, previous to being burned or consumed, and improvements in the apparatus for these purposes.

Dated December 2, 1867.

3421 W. Black and T. Hawthorn, Gateshead, Durham. Improvements in valves for steam engines.

Dated December 12, 1867.

3530 N. Paxman, jun., of Clifton Hampden, Oxfordshire, farmer. Improvements in steam cylinders and the peculiar arrangement of the mechanism connected therewith.

Dated December 13, 1867.

3542 E. B. Sintzenich, Duke-street, St. James's. Improvements in the treatment of gutta-percha, india-rubber, Honduras gum, and the other allied gums, for the production of a preparation or preparations applicable as a varnish, cement, paint, stain, water and air-proof material, solid or elastic material, and for other purposes. (A communication.)

3543 G. Whitehead, Newcastle-on-Tyne, chemist and druggist. Improvements in capsules or coverings for bottles and other like vessels.

3548 L. A. Damm, Seething-lane, City. Improved appliances and means for conveying salt water fish through fresh water and overland and on land. (A communication.)

Dated December 14, 1867.

3556 A. McMurdo, Rear-Admiral in the Royal Navy, Cargenholm, Dumfrieshire. Improvements in apparatus for saving life from drowning.

Dated December 18, 1867.

3597 T. Comfield, jun., Queen's-road, Buckhurst-hill, Chigwell. Improvements in breaks for railway and other carriages, and in signalling and other apparatus in connection therewith, which improvements are also partly applicable to other purposes.

3598 W. Preston and C. Walker, Dewsbury, York, overlookers. Improvements in machinery known as the condenser carder.

Dated December 19, 1867.

3605 E. T. Bellhouse, Manchester, engineer. Improvements in the construction of fireproof floors for buildings.

3607 W. A. Hubbard, Ramsgate. Improved proportional compasses and dividers.

3608 J. S. Gisborne, Liverpool, electrical engineer. Improvements in electric telegraphic apparatus, and in the symbols or characters connected with the transmission of messages by electric telegraphs.

3609 L. M. Becker, Guildhall Chambers, Basinghall-street, London, telegraphic engineer. Improvements in the arrangement of electric telegraph and other wires and the apparatus employed or connected therewith, and in laying and supporting wires for telegraphic or other purposes.

3611 J. Clay, Yardley, Worcestershire, saddler. Improvements in saddles.

3613 E. Breffit, Castleford, York. Improvements in glass bottle house pot carriages, and implements used in setting glass bottle house pots, which invention admits of improvements in the construction of furnaces for melting bottle or other glass in open pots.

3615 R. Chauncy, Clyde-street, Brompton. Improvements in the preparation of a substitute for emery paper.

3617 J. Simmons, Ravenscourt Park, Hammersmith. The purpose of producing an optical illusion of apparently beheading or otherwise dismembering a human being.

3619 C. Beck, Queen-street, Cheapside. Improvements in joining horn and whalebone.

Dated December 20, 1867.

3621 H. A. Bonneville, 38, Porchester-terrace, Bayswater. Improvements in machinery for carding and spinning wool and other fibrous materials. (A communication.)

3623 E. Field, Chandos Chambers, Adelphi, Westminster, consulting engineer, and F. P. Warren, Norwood, Surrey, Commander in the Royal Navy. An improved cowl for chimney tops.

Dated December 21, 1867.

3627 J. Kenyon, Blackburn, Lancaster, cotton manufacturer. Improvements in apparatus for boiling size.

3629 C. de Bergue, Strand, engineer, and W. Dredge, Buckingham-street, Strand, civil engineer. Improvements in the construction of and mode or modes of connecting and working railway carriages or trains.

3630 W. Walker, Rochdale, and E. Holt, Newton Heath, Lancashire. Improvements in direct-acting double-action steam pumps.

3633 J. Davidson, Woolwich. Improved machinery for manufacturing central-fire cartridges.

3637 J. Davison, Bishopswearmouth, Durham. Improvements applicable to the rigging, chains, windlasses, anchors, and other parts of ships or vessels, or to collieries, railways, rolling stock, or other purposes, to prevent sudden blows, jerks, or strains.

3639 J. G. Tongue, Southampton-buildings, Chancery-lane, engineer. Improvements in the manufacture of pomade for the human hair. (A communication.)

Dated December 23, 1867.

3641 W. Dixon, Maple-street, and W. Brown, Gray-street, Newcastle-on-Tyne, engineers. An elastic coupling for the prevention of sudden or undue strains upon ropes or chains, when used in towing, hauling, or lifting.

3643 W. W. Urquhart and J. Lindsay, Dundee, engineers. Improvements in machinery for softening jute, hemp, and similar fibrous materials.

3647 C. J. Adams, Stockton-on-Tees, architect. A self-acting fire alarm and extinguisher.

3649 J. Dawkins, Pembroke, tanner and currier. Improvements in tanning, and in the apparatus to be employed therein.

3651 M. J. Rice, Sherlock-street, Birmingham, engineer. Improvements in machinery for cutting and heading nails.

Dated December 24, 1867.

3652 F. A. Abel, Royal Arsenal, Woolwich. Improvements in the production of explosive compounds.

3653 S. Myers, St. George's-road, Kilburn. Improvements in apparatus for roasting coffee. (A communication.)

3654 W. Burley and W. H. Glasson, Landport. Improvements in the construction and arrangement of plummer blocks and bearings for propeller shafts, and other analogous purposes.

3655 P. F. Tranchat, Rue Gaillon, Paris, engineer. A universal machine for manufacturing circular cutters and milling tools of any form or outline, with either a rectangular or a helicoidal direction of cut.

3657 A. M. Clark, Chancery-lane. An improved colouring matter, chiefly applicable for dyeing and printing purposes. (A communication.)

3659 G. Layton, Liverpool. An improvement in the manufacture of soap.

3660 F. Render, Manchester, corn merchant. Improvements applicable to traps for pigeon and other shooting.

3661 T. Harbison, Manchester. Improvements in rails for railways.

3662 W. E. Newton, Chancery-lane, civil engineer. An improved alcoholmeter or instrument for ascertaining the alcoholic strength of liquids. (A communication.)

3663 J. Addie, Langloan Ironworks, Coatbridge, Lanarkshire, ironmaster, and F. Kohn, Westminster, civil engineer. Improvements relating to blast and cupola furnaces.

3664 G. E. Allshorn, M.D., M.R.C.S., Ludgate-hill, City. Improvements in the manufacture of artificial fuel.

3665 S. Lennard, Newark-street, and F. Lennard, Belgrave Gate, Leicestershire Improvements in the manufacture of warp fabrics.

3666 W. Hewitt, Birmingham, manufacturer. Improvements in holders for holding or gripping reins, whips, and other articles.

3667 G. J. Hinde, Wolverhampton, manager, and T. C. Hinde, Ynispenllwch, near Swansea, Glamorganshire, colliery proprietor. Improvements in the manufacture of iron and steel, and in furnaces and apparatus used in the said manufacture.

Dated December 26, 1867.

3670 B. and J. B. Bowen, Chipping Norton, Oxfordshire. Improvements in the manufacture of gloves.

Dated December 27, 1867.

3672 E. G. and E. E. Raffer, Rue d'Enghein, Paris. An improved braiding machine.

3674 E. J. Hughes, Manchester. Improvements in blankets used in machines for printing textile fabrics, and in the mode of joining together the ends of double-woven fabrics. (A communication.)

3676 J. Cockshoot, jun, coach builder, and H. Weatherill, Manchester, manager. Certain improvements in railway breaks.

3678 D. Steele, Farnworth, Lancashire, manufacturer. Improvements in apparatus for heating and agitating liquid or fluid substances.

3680 J. Clark, Redditch, Worcestershire, needle manufacturer. Improvements in wrappers or envelopes for needles.

3684 C. E. Brooman, Fleet-street, patent agent. Improvements in the application of electricity to clocks, watches, and other timekeepers, and in the apparatus employed therein. (A communication.)

Dated December 28, 1867.

3686 J. Capper, Birkenhead, accountant. Improvements in the construction of chimney tops or caps.

3688 A. V. Newton, Chancery-lane, mechanical draughtsman. Improvements in the mode of and machinery for making shot and shells for ordnance. (A communication.)

3690 W. E. Newton, Chancery-lane, civil engineer. Improvements in motors or apparatus for generating motive power, and in the method of applying the same to produce useful effect. (A communication.)

3692 R. Howarth, Southampton-buildings, Chancery-lane. Improvements in carriages, railway trucks, and other vehicles.

3694 E. Evans. Peacock-street, High-street, Newington Butts. Improvements in the construction of the sash frames and boxings of windows and shutters, and in the mode of hanging the sashes of windows.

3696 C. Churchill, Norwood, merchant. An improved gas burner. (A communication.)

Dated December 30, 1867.

3698 R. Fothergill, Abernant House, Aberdare, Glamorganshire. Improvements in the process of and apparatus for producing heat by the combustion of fuel for metallurgical and other operations where heat is required, and in the means for utilizing the waste heat from blast furnaces.

3700 W. Kendrick and J. Wooldridge, West Bromwich, Staffordshire, ironfounders. Improvements in the apparatus for consuming or preventing the formation of smoke in steam boiler and other furnaces.

3702 J. Davison, Bishopswearmouth, Durham. Improvements in furnaces for smelting glass, or the materials employed therein, and for consuming smoke.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated January 3, 1868.

3 W. R. Lake, Southampton-buildings, Chancery-lane, consulting engineer. Improvements in electric telegraph apparatus. (A communication.)

Dated January 3, 1868.

27 M. J. Frisbie, Fitzroy-square. Improvements in mechanism or apparatus for feeding fuel into furnaces, fire-boxes, and fire-grates.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," January 14, 1867.

2473 I. Dixon. Submerged propeller.
2474 M. Hammerstein. Smoking tubes. (A communication.)
2489 A. Field and W. B. Nation. Ornamenting candles.
2492 A. E. Gelhaye. Chains.
2495 L. N. Le Gras. Milk-cans.
2501 W. Weldon. Artificial oxides of manganese.
2503 F. B. Dœring. Working in rock.
2504 J. K. Smythies. Carrying passengers through the air.
2509 R. A. Jones and J. C. Hedges. Fire-escapes.
2510 A. C. Henderson. Applique embroidery. (A communication.)
2513 H. Carter and G. H. Edwards. Breech-loading firearms.
2514 G. Cope. Shaping cigar bunches.
2515 J. Ford. Securing wheels.
2521 H Gardiner. Miners' safety lamps.
2526 W. G. Creamer. Excluding dust from railway carriages.
2527 T. W. Helliwell. Looms.
2528 A. M. Clark. Ships.
2534 J. B. Rogers. Projectile anchor.
2539 B. F. Stevens. Illuminating roof.
2544 E. J. C. Welch. Artificial ice.
2547 W. R. Lake. Cartridge holder. (A communication.)
2548 C. E. Brooman. Hydrogen. (A communication.)
2554 J. Turnock. Cask stands.
2558 J. Dicken. Yielding fishplate.
2564 J. Rae. Filtering water.
2570 S. Brown. Ornamenting bottles.
2580 W. F. Cooke. Quarrying slate.
2584 J. Perrin. Fuel economizer.
2590 P. R. Couchoud. Chenille.
2593 W. F. Batho. Cooling liquids.
2595 J. M. Napier. Wine glasses.
2597 W. Whitehead. Printing fabrics.
2603 R. Canham. Sharpening knives.
2607 J. A. M'Kean. Cutting rocks. (A communication.)
2617 S. C. Amesbury. Communicating between railway trains.
2644 A. M. Clark. Colouring artificial flowers.
2662 B. and A. B. Blackburn. Lucifer matches.
2686 H. Forbes. Rotary pumps.
3075 R. B. Roden. Breech-loading firearms.
3106 A. V. Newton. Sewing machines. (A communication.)
3148 J. F. Brinjes. Cooling liquids.
3193 F. Ransome. Grindstones.
3292 J. Owens. Pile fabrics.
3311 A. Munro. Cutting rocks.
3341 E. Townshend. Tobacco pouches.
3471 S. Goldstein. Wearing apparel.
3483 R. B. Jones. Prevention of incrustation in steam boilers.
3496 W. H. Cooke. Door springs.
3523 G. A. Young. Curtain.
3572 J. E. A. Gwynne. Sinking tubes.
3688 A. V. Newton. Making shot. (A communication.)
3 W. R. Lake. Electric-telegraph apparatus. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed January 11, 1868.

2040 E. Hohenbruck	2108 T., J., and J. Palmer jun.
2045 F. Wilkins	2112 R. T. Bradbury and T. Bottomley
2047 W. B. Haigh	2186 E. Ravenscroft
2065 H. Fletcher	3066 J. T. Caird and S. Robertson
2067 E. T. Hughes	
2076 J. M. Hetherington and R. W. Pittield	
2180 P. A. Rohart	

Sealed January 14, 1868.

2078 A. B. Ibbotson	2117 G. T. Bousfield
2079 T. Redwood	2129 W. Potts
2082 F. B. Vallance	2158 C. H. Murray
2085 G. W. Hayes	2166 C. E. Brooman
2086 J. Mannock	2168 G. L. Barens and J. F. Ladougne
2087 W. M'Andrew	2234 J. Edwards
2088 T. Pirie	2282 E. T. Horsley
2094 G. Weedon	2294 H. A. Avery and G. Penabert
2096 A. de Smet	2408 A. M. Clark
2098 G. H. Daw	
2106 A. Morton.	

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

50 T. Richardson and M. D. Rucker	101 F. Barnes
55 G. B. Galloway	119 G. Davies
60 J. J. Blackham	127 J. Young
77 H. Chamberlain	129 F. C. Fourgeau
82 J. F. Spencer	130 J. B. Farrar
89 J. Ramsbottom	164 R. Mallet
95 R. Chidley	166 W. C. Hicks
96 J. G. Jones	228 J. Hamilton
	725 H. Owen.

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

62 S. Moulton	88 W. Bullough
89 G. Whight	194 T. Gibson and W. and H. Knighton

THE

MECHANICS' MAGAZINE

LONDON: FRIDAY, JANUARY 24, 1868.

DR. LIVINGSTONE.

THE Livingstone search expedition has returned, and has brought with it news of an assuring, although not entirely satisfactory, character. We have always looked upon the hopeful side of this question, and have believed in the safety of our great African explorer—at least, as far as regards a violent death. This we have been enabled to do simply because the balance of evidence was in favour of such conclusions. Sir Roderick Murchison has ever been most sanguine, and he now has not the shadow of a doubt that the white man seen on the west side of Lake Tanganyika was Dr. Livingstone. We are heartily glad to hear it, and we believe that this will prove to be correct. Turning to the report of the members of the expedition, we find that Dr. Livingstone did not take the route expected from the Ruvuma River at about 11deg. S. along the north coast of Lake Nyassa in from 36deg. to 34deg. E., but from the Ruvuma went south round the south end of Lake Nyassa, going as far as 14·28deg. S. Thence he proceeded to the north-west, and was left pursuing that route either with the view of exploring the west coast of Lake Nyassa, and thus ascertaining how far it extends north, and then to proceed on to Lake Tanganyika, or he had gone direct for Tanganyika, and thence down the Nile home. Mataka, Makata, Marenga, and Maksura, mentioned by the Johanna men, were found on the southern route instead of the northern. The expedition followed Dr. Livingstone up to within a few miles of where it was reported he was murdered, and there found that the doctor and his "boys" were ferried over a marshy lake by Marenga, but the Johanna men under Moosa made a detour round the lake and returned next day to Marenga, saying they had deserted Livingstone and should return to the coast, because he was leading them to a country where they would be murdered by the Mavite. The expedition also had interviews with the native porters who had carried Livingstone's luggage five days' journey further to Pasombe. This is confirmative of Sir Roderick Murchison's oft-repeated conviction that the doctor had proceeded into the interior.

So far, we are well pleased with what the expedition under Mr. Young has done. But the question which occurs to us is, could they not have done a little more? The safety of the indefatigable traveller has only been proved negatively; could not the expedition have afforded some positive proof on this point, and thus have set at rest all doubts and uncertainties? We were ourselves somewhat surprised at the early return of the expedition, but attributed it to extraordinary success in their investigations. Some experienced African travellers, however, are inclined to think the return of the expedition somewhat hasty, and that it is possible, after all, that the natives were clever enough to say that which they thought would please rather than what they knew to be the fact. It appears that deception has certainly been practised on the expedition in one instance, and it was in this way:—The leaders of the expedition were specially instructed to recover, if possible, some papers known to have been left by Dr. Livingstone with a chief on the borders of Nyassa. When five days' journey from this chief's village, Mr. Young dispatched a few of the natives to the chief with presents, to obtain the papers desired. These natives returned eight days afterwards, however, with the story that the documents were lost or destroyed. With this answer, Mr. Young was so far content that he did not think it necessary to take steps to corroborate the information. This is to be regretted, as we find that on the return journey it was elicited that the messengers had halted when they had gone one day's journey, had bartered the cloth and beads sent to the chief as presents for personal refreshment, and afterwards returned to the Europeans with a lying story as to the missing papers. Moreover, the absence of the messengers was suspiciously less by two days than it had been calculated it would be. This circumstance should have been sufficient to have induced an investigation into the matter, and the dispatch of other messengers under trustworthy supervision. Indeed, it appears to us that this should have been done in the first instance. Surely, one of the European members of the expedition, if not the leader himself, should have accompanied the native messengers. And why not, when their trick was discovered, have retraced their steps, and have proceeded to the village where the papers were supposed to be? Surely, there is some want of heart in the matter. It is true, we have reason to hope, that these documents are now on their way to England; but how much more satisfactory and assuring to have had them here now? We repeat that the members of the expedition have done well in proving the safety of Dr. Livingstone by a negative process, but they would have done far better had they endeavoured to prove it positively. We might even go farther and suggest that, having so easily satisfied themselves of the fact that Livingstone had not been murdered, the expedition might have pushed on in his wake, and have ascertained a little more of his actual existence and whereabouts. We write, of course, under the disadvantage of non-acquaintance with the local conditions and other circumstances attending the expedition, but we write with a feeling of disappointment which must be shared in by every friend of the great explorer. We shall, no doubt, hear the details of the expedition next Monday evening at the Geographical Society's meeting, when a little more light may be thrown upon the matter. Besides, we are looking for Mr. Young's narrative, which is to be published. This, we believe, will be followed by a pamhplet from the pen of Captain Faulkner, who accompanied the expedition; and as the narratives are expected to be somewhat dissimilar, if not contradictory, we shall have the opportunity afforded of judging of the conduct of the expedition. Meantime, we continue hopeful as to the safety of our great traveller, and believe that we shall see him amongst us yet again.

THE AMERICAN RAILWAY CONSTRUCTOR.

THE Union Pacific Railroad presents an example of rapid construction unparalleled in the history of American railway formation, much less of our own. Granted that the lines in the States are for the most part less substantially made than ours are, still we could not construct them even in a similar manner in the same time. Much of the material is so well to hand, and there is such ample room for whole troops of workmen to move in, that with discipline and order the progress made in this class of work is really astonishing. On the 9th of May, 1866, forty miles of the Union Pacific Railroad were completed, but in 182 working days from that date 245 miles more were laid and put in prime condition, every rail, sleeper and spike being brought up from the rear. Seven saw-mills furnish the sleepers—or, as the Americans call them, "ties"—and lumber, and all the bridges are framed, the pieces being numbered and fitted where wanted without delay. In this way was constructed a bridge at Loup Fork, 1,500 feet long, on the Howe principle, and which is as fine a truss as any put up in the States. On the 1st of January, 1867, 305 miles of this railroad were completed, and by June last 500 miles were in working order. There yet remains much work to be done, and during the past winter some heavy rock-cutting has been accomplished. The work at the California end of the route is being energetically pushed forward towards the east, and it is expected that the whole grand line to the Pacific will be open in 1870.

The way in which this important work is being so rapidly carried out deserves a brief allusion here, as well on its own account as that it will contrast with what we shall presently have to say. Two engineer officers lead the way, laying out the work, fixing the gradients, laying down the track, and putting up the telegraph. With these officers are first 2,000 navvies, or "graders," as the Americans term them. Next there are 1,500 timber getters and tie makers, then follows a small army of tie layers carefully performing their share of the great work. Twenty miles behind these workers are the construction trains loaded with materials. Beyond these again some miles is another grand reserve of trains of a similar character. Near the working party, and following it hour by hour, as the line advances, are the boarding cars and a construction train. The boarding cars are 80 feet long, and include dining rooms, sleeping berths, kitchens, store rooms, and offices. The boarding cars go in advance, followed by a construction train, which unloads, and then goes back for fresh supplies. The boarding train is then run back beyond the unloaded materials, and trucks are placed on the line which supply them to the tracklayers. The arrangements throughout are the very embodiment of system, and this is the key to the rapidity with which the work advances.

One would have supposed that this rate of progress would have contented any nation. We should have been—nay, we are—satisfied with very much less. Fancy a line of railway from London to the Land's End constructed in less than two-thirds of a working year. But this rate is not sufficient for our transatlantic friends. A people who peel their apples, shell their peas, and stone their plums by machinery, must of necessity construct their railways by the same means. So we find them bringing out a railway constructor, which is certainly one of the most remarkable machines we have ever heard of. Its birthplace is San Francisco, where it has been tested in the presence of all the local authorities, and pronounced to be a perfect success. Its invention is due to Mr. D. W. Robertson, of Star City, Humboldt, Nevada, who pithily describes it as an apparatus which, by a combination of movements, will level the loose surface of the soil, place the ties at uniform distances, follow any curve, and accommodate itself to ordinary gradients, deposit the rails with the chairs attached, and nail them securely in their places. It is estimated that, with a complement of twenty men, it will do as much work as two hundred men can without its aid. We gather from the San Francisco "Bulletin" that the machine is comprised within a frame 60ft. long, 8ft. high, and 12ft. wide, and with its trusses, struts, and tie-rods, has the appearance of the skeleton of a wooden bridge placed on a low railway truck. The frame, however, is only supported over the truck wheels one-third of its length; the forward part of the frame, which is two-thirds of the whole, overhangs the ground on which the track is to be laid. To preserve the balance of the apparatus, the heavy stringers, which give strength to the machine, taper gradually to the front, so that without the engine and boiler, or any load of ties, rails, or other ballast, there is no possibility of its tipping forward.

When completed for actual service, it will

Digitized by Google

be fitted with a ten-horse power engine, which will be placed between the two supporting trucks, and with twenty or thirty rails laid lengthways, and a ton or two of ties stored transversely at the extreme rear, the suspended portion, when the concern is in motion, will be as firm and solid as if supported on wheels the entire distance. As the machine travels forward, it will move on rails of its own laying. In front of the machine is a plough which levels the ground for the permanent way. The ties are brought from the back over the machine and above the heads of the workmen by two endless chains, and are laid on the ground in front exactly in the position required. On each side of the motive power, on the rear of the platform, are the stacks of rails, which are picked up singly by clamps connected with a hoisting apparatus raised to a sufficient height, and while in suspension are run forward by means of overhead cars and tracks till they hang over the spot they are destined to occupy. The chairs are slipped over the rail ends as they travel, and at a signal by the foreman the rails are lowered by machinery to their places. The chairs have then only to be nailed firmly to the woodwork, the spikes driven home, and the work is complete, and the machine moves on over the road it has just constructed. Fresh ties can be constantly supplied by the track behind without stopping the work. When the gradient rises or falls, the front of the machine is elevated or depressed to a fractional part of an inch by a system of rods and set screws, which perfectly adjust the machine to its work. The constructor will, if necessary, turn itself on a radius of 200ft. The position of the managing engineer is on a platform built above the heavy framing of the machine, where, housed as comfortably as the pilot of a river steamer, he can overlook all the machinery in the work, direct, and control, and survey the ground ahead, and view the finished line behind. Such is the new constructor which is to revolutionize the system of railroad construction by laying a track at the rate of from six to twelve miles per day. Should the Union Pacific Company take to this machine, they will finish their work in far less time than they will under the present system of manual labour. Repeating our parallel, with the aid of the constructor working at the slower of the two rates named, we can say,—Fancy a line of railway from London to Land's End constructed in forty-one days!

NEW SYSTEM OF GASLIGHTING IN PARIS.

OF all the practical applications of science to the welfare and comfort of civilized nations, that of gas is unquestionably the most valuable and most conducive to public convenience. In spite of many attempts to manufacture gas from other sources than coal, it has nevertheless remained as the material "par excellence" from which to obtain that illuminating luxury. So far back as the year 1838, London possessed upwards of twenty gas works, representing a capital of three millions invested in apparatus, mains, and pipes. The great difficulty to overcome in manufacturing gas from coal was the purification, which at the present day cannot be said to be altogether vanquished. In many towns the reverse is the case, and the gas is far from possessing that brilliancy and illuminating power which should be the result of it attaining the orthodox standard of the light of so many wax candles. Some years ago, gas evincing superior powers of illumination to that manufactured from coal was produced from oil, by bringing that substance into contact with coke in a retort heated to redness. A company was started in London to carry out the project. The oil in this situation becomes decomposed and converted into a volatile gas, which being altogether destitute of sulphur and those ammoniacal ingredients which adulterate coal gas, requires no purification. Notwithstanding this great advantage, owing to the comparatively high price of the material, and other circumstances—possibly the strenuous opposition of the existing companies—the scheme proved abortive, and the undertaking was abandoned. The fact, however, that gas produced from coal is not the best description of artificial light that can be procured has long been the opinion of chemists and scientific men. To bring the matter to a crisis, a company has been quite recently established in Paris to light that city with an illuminating medium of a new description. The proposed method of illumination may be termed new when applied upon a scale so vast as that under consideration, but viewed simply as a means of producing a brilliant light, it is familiar to every chemist or even student of the laboratory. Most of our readers are possibly acquainted with the vivid light obtained by what is termed the oxy-hydrogen process, and can recall to their minds the dazzling effect produced by throwing an incandescent jet of this compound gas upon a piece of chalk.

The Parisian Gas Company propose to illuminate Paris by means of igniting the gas formed by the union of oxygen and hydrogen. One of these elements, namely, oxygen, is not "per se" an inflammable gas, but rather the agent or a source of combustion for other substances. This is apparent from the simple and elementary experiment of burning bits of phosphorus, or a bit of red hot wire in a receiver of oxygen. The gas does not take fire and suddenly blaze up, but performs the part of a feeder, as it were, to the combustion already set up in the substance placed within its influence, which it at once intensifies and maintains until it is itself exhausted. Very opposite features characterize the other component, hydrogen. It is inflammable, but when burning emits only a feeble light, although its flame possesses a very high temperature. When mixed with a certain proportion of air it is rendered explosive. Apropos to our subject, it may be remarked that its diffusive power is so great, that it becomes no easy matter to secure it in a receptacle which shall totally prevent its escape. The immediate application of a light to certain proportions of these two gases, as is well known, determines their combination, producing water, but by adopting precautions the compound jet may be burned in a manner similar to that of the ordinary coal gas. A peculiarity of the flame of the oxy-hydrogen light is that it is solid, and not hollow, as is the case with other illuminating agents. In fact, independently of what the actual flame may be composed of, it is oxygen which really supports all combustion, and it therefore appears at first sight the proper medium to utilize, if possible, and cause it to be a principal instead of playing a merely subordinate part. Assuming, therefore, that it is proposed to employ pure oxygen in place of that existing in the air, it is evident that the first step is to obtain means of procuring that gas in a state of purity, at a cost which will prove remunerative. Granting that this indispensable step is achieved, the utility may be questioned of establishing expensive reservoirs, and laying down a costly system of mains and branch pipes to supply that which can be obtained from the air gratuitously. It must, however, be kept in view that it is one thing to supply a flame with oxygen diluted, or rather adulterated, with four parts of nitrogen, and another to feed it with that gas in a state of purity, and supplied, moreover, in the exact proportion required, so that from the mixture is obtained the maximum illuminating and warming effect that the constituent elements are capable of developing. At the same time, a light too vivid is insupportable—the electric light, for instance—and the ordinary gas flame has frequently to be toned down and softened by globes of muffled glass. From a peculiar class of schist, from many resinous substances, and other sources, all possessing a large proportion of carburetted hydrogen, an excellent gas can be procured, endowed with a high power of illumination. The practical impediment to its employment is that during its passage through long pipes it loses, by condensation and other causes, those very elements which render it valuable.

Although we have stated that the object of the new Parisian Company is to use a gas produced by the union of hydrogen and oxygen, yet it must not be supposed that the process is identical with the well-known oxy-hydrogen light. The project to be carried out does not consist in adopting any other method of illumination than that arising from the use of the ordinary gas, nor does it include any new method of manufacture of that substance. In a few words, it is simply a new plan for burning or consuming the gas already supplied to the city. We now return to the question of the feasibility of producing upon a large scale the quantity of pure oxygen required for the execution of the intended scheme. Evidently the source from which this gas is to be derived must not only contain it in great abundance, but must also be capable of yielding it up with what might be called "very little persuasion." It must not in any sense come under the category of what are known to chemists as refractory bodies, or those which refuse, except under very strong pressure, to part with the particular constituents demanded of them. Manganate of soda is the substance at present considered to possess these qualities, and it is therefore proposed to give it a trial. The element manganese, especially in the binoxide, $Mn\,O_2$, is a fruitful source of oxygen, and is often used for the production of that gas. By submitting the manganate of soda to the action of heat, it first yields up its oxygen, then draws a fresh supply from the air, which it again parts with, and this process of loss and recovery continues for an indefinite period. There is another and a grave difficulty to be surmounted in furnishing the actual quantity necessary, without reference to the mere price. In a period of twenty-four hours each retort could supply only 9 cubic yards of oxygen, which is a very small quantity compared with the 220 cubic yards of coal gas furnished by each existing retort in the same interval of time. The result of a calculation demonstrates that nearly 12,000 retorts for the production of oxygen would be needed, while the total of those used for the manufacture of coal gas is but 2,000. Conceding that both in quantity and quality the oxygen can be produced and stored in suitable reservoirs, the next step is to convey it to its destination, and this involves a task of no ordinary magnitude. Owing to the tremendous explosive powers of the two gases when mixed, and ignited without due precaution, the oxygen and the coal gas could not be conveyed in the same pipes. The former must, therefore, have a special service of its own, and also one in every respect superior to that given to its neighbour. Coal gas is so readily manufactured, that, comparatively, its value is not very high, and companies are quite satisfied to regard with indifference the enormous loss that occurs through leakage and bad manipulation of the pipes. It has been alleged that so much as 50 per cent. of all the gas made in London is lost in one way or another. When, however, it becomes a question of transporting a substance which under the same volume possesses a much higher value than coal gas, the service pipes must be laid in a better manner, and the whole system attended to with a commensurate degree of vigilance and precaution. In addition to entailing a new set of pipes, all the present burners would be useless under the proposed system, and it would be necessary to replace them with others adapted for the employment of a solid instead of a hollow flame. Reviewing all the points to which we have drawn attention, the truth of the

Digitized by Google

economy of the project, as announced, is not altogether apparent. The projectors of the scheme intend employing the oxygen in the proportion of about a fourth of the coal gas, so as to increase the intensity of the illuminating power nearly eight times. Firstly, can this result be accomplished? secondly, if it can, will it be more economical than the present system? Taking the relative values of coal gas and pure oxygen as 1 to 7, it is evident that in order that the price should remain the same, the quantity of gas consumed by the proposed plan should only be one-seventh of that burned at present. But the quantity of light developed by a burner, is proportional to the area of the flame for a given intensity. If oxygen be the illuminating agent, the intensity will be greater than that of the same quantity of coal gas consumed in a given time; but since the combustion of the former will be more energetic, the area of the flame will undergo a corresponding diminution, which may be estimated at one-fourth. As the quantity of gas is reduced to a seventh, the actual flame is, therefore, represented by a twenty-eighth, and, consequently, instead of an illuminating power of seven times the intensity of coal gas, one of twenty-eight times is required to maintain an identity in the cost. Unless the manufacture of pure oxygen can be reduced to a price less than 1s. per cube yard, which is certainly assuming a condition of affairs for which there is no warrant, it is scarcely possible that the new project will be found to succeed. With respect to a city similar to Paris, there are many additional disadvantages which a company of this description has to contend against which are unknown to ourselves. Our streets are common property, and anyone who owns a few yards of piping may prove his title to "a right of way" by ripping up the road, obstructing the traffic, and causing a local nuisance for almost any length of time. There is not a single main thoroughfare in London that is not disembowelled at least once every three months. Matters are otherwise managed on the other side of the Channel, and in connection with our subject it may be remarked that the ground is already occupied by an existing company whose interests would be carefully protected. There is another feature presenting itself worthy of consideration. The City of Paris levies a duty upon every cube yard of gas consumed. If, therefore, the employment of pure oxygen will reduce the annual consumption of that article to one-seventh of the original quantity, there is no question but that in order to preserve the total amount of the rate unaltered, seven times the duty will be levied off the oxygen which has caused the decrease.

MOLECULAR VIBRATIONS CAUSED BY THE ELECTRIC CURRENT.

IT has long been known that a thin wire which has conducted a current of electricity for some time becomes somewhat shorter and, as it were, crinkled, or it may be slightly spiral, also that it becomes harder by use; but a more decided proof of these molecular vibrations in a metallic conductor of electricity, as we think, has come under our notice than anything we have seen noticed by any experimenter. Some time ago we were engaged in some experiments for the deposition of iron from various solutions, such as sulphate of iron, chloride of iron, ferrate of potash, and ferrocyanide of potassium. For the deposition of iron from the first three solutions, an intensity of one cell only being necessary, the molecular vibrations are but slight, but for the deposition of iron from ferrocyanide of potassium, under the most favourable circumstances, not less than three cells are effective, and, even with these or higher intensities, the phenomenon we are about to name does not always take place.

The conditions under which the experiment was made are these. In an outer cell, containing common salt and water, was placed a porous cell, within which was a saturated solution of ferrocyanide of potassium in the cold, to which was added one-third its weight of pure potassa; this potassa was to take up any carbonic acid gas that might be disengaged from the ferrocyanide solution. The whole was then placed in a chafing dish containing water which was kept at 150deg. Fahrenheit. A positive electrode of gas carbon was placed in the outer cell in the salt and water. Within the porous cell the steel blade of a knife was placed as a negative electrode. Three cells of Daniel's battery were then attached with a regulator, and the current was adjusted till there was just a slight evolution of hydrogen at the negative pole. The apparatus was kept in action for four hours. The steel blade before being placed in the solution was thoroughly cleaned and examined, and was perfectly sound. At the end of four hours it was taken out to ascertain the amount of iron deposited, and it was found that there were two cracks in the steel from the edge towards the back; the longest being about a quarter of an inch. This being so unexpected, the blade was again placed in the solution for four hours more under the same conditions, and again on examination it was found that there was another crack; but this time from the back towards the edge, and the other cracks were extended somewhat. A third time it was subjected to the same treatment, and another crack was found much longer than the others in another part of the blade, from the edge towards the back as the first ones.

If this last crack had been directly opposite to the one produced in the second experiment, the blade would have parted, because the two cracks together were longer than the width of the blade. Similar results have been produced in later experiments, though not to the same extent. No doubt these results are produced by the molecular vibrations of the metal while the current is passing, but it is only in exceptional cases that they occur, and they are doubtless owing, when they do occur, to some inequalities in the steel, either in density, composition, or temper; for in most steel blades no such thing happens, nor in blades of brass or copper, nor in a very hard and brittle alloy of copper and tin. Apparently, if the metal be perfectly homogeneous no such thing happens. The cracks are altogether similar to those produced in steel, when it is hardened by being plunged into cold water, and these, it is well known, are the results of unequal contractions, whether from injudicious manipulation or from inequalities in the structure of the metal. And this latter cause is probably the reason of the electric cracks. However, these experiments prove this fact in a new form, that any metallic electric conductor conducts with its whole substance. This is a fact well known to electricians, and though sometimes it has been disputed, yet it has been abundantly proved to be the fact, but we think never in so striking a manner.

There is another matter that we think it also bears upon, which has been much in dispute. That is, whether electricity is a fluid or simply a peculiar form of vibrations of material molecules. Certainly of late this latter notion has much gained ground, to the exclusion of the irrational theory of an imponderable fluid. Light now is considered to be motion, heat also is considered to be motion, and without doubt electricity is motion, and moreover these motions are convertible.

At the present time, Professor Tyndal, in his lectures on heat and cold, is teaching this doctrine of molecular vibrations to his juvenile audience in a very simple but very effective manner, by means of a row of solitaire balls. The first being struck, motion is communicated to the last, not by the transmission of anything, but by each communicating its vibration to its neighbour; and we think such an illustration of electric conductivity is also applicable, and not only so, but it is most appropriate. Many who hold electricity to be a force and not matter, have considered that the most apt illustration of an electric current was that of water flowing through a pipe, quantity being represented by the bore of the pipe, and intensity by head of water. But why not take the musical vibrations of a string, or the air of a musical pipe, or the vibrations of the reed of a harmonium, for here we have something like the compass necessary to represent electric intensity, the vibrations ranging from about two thousand in the second to many hundreds of thousands. However, we will leave this for the consideration of electricians, but think that our experiment at least proves this, that an electric current is manifested by the molecular vibrations of the conductor.

RAILWAY ACCIDENTS.

THERE should not be, of course, any preventable accidents, but accidents will happen, it is to be feared, while the world endures, or, at least, until the millennium arrives. Some classes of casualties receive quite as much attention from the press and the public, and some others, again, much less than their numbers and character respectively entitle them to. Railway accidents are almost invariably thoroughly ventilated, and full publicity is given to the details, both before and after the scrutiny of the Government inspector, sent by the railway department of the Board of Trade, who reports upon the casualties which the companies are bound, under penalties, to report to the Board. There is much less alarm excited by, and much less known concerning, the far more numerous fatal accidents that occur in connection with horses and vehicles in the streets of London. Often there are as many such fatal accidents in a week as there are upon all the railways in the United Kingdom in a year. There is, of course, when a person is killed, a coroner's inquest, a verdict in accordance with the evidence, a two line record in the Registrar's fortnightly return, and there an end. It is a startling fact that to those who tread the streets of London the chance is ten times greater of their being killed in the streets than of their being killed by railway travelling. A curious calculation has been made, in vindication of the rail, with all its imperfections, as by far the safest mode of travelling now practised, or ever known; that a man runs a greater chance of being struck dead by lightning, or actually of being hanged, than of his being killed by railway travelling. The chances of the last-named mode of departure from this life are of course based upon figures, and apart from any moral considerations.

From the Board of Trade railway returns just published it appears that in 1866 there were fourteen passengers killed on railways by causes beyond their own control in England, and one in Scotland; in Ireland not a single passenger was killed or hurt. Of the six accidents in which lives were lost, two, involving nine deaths, are of an exceptional nature, and can scarcely be regarded as attributable to railway travelling, in the ordinary sense. In one of these cases, where six persons were killed, the accident occurred on the Carnarvonshire Railway, upon which the contractor ran an excursion train before the line was inspected. In another instance, upon the Metropolitan, an iron girder fell upon a passing train and killed three persons. The passengers who lost their lives were one in above 20,000,000, and the passengers injured one in about 600,000. There was no fatal accident to passengers upon the systems of any of the great companies, excepting the Brighton and the North-Eastern. The London and North-Western, the Great Western, the Great Northern, the Great Eastern, the Midland, the South-Eastern, the Lancashire and York-

Digitized by Google

shire, and the Manchester, Sheffield and Lincoln, all conducted their enormous traffics without the loss of a passenger's life. On the South-Western there was not even an injury of any kind sustained by a passenger. In Scotland, the Caledonian, the Great North of Scotland, the Highland, and the North-Eastern, conveyed the whole of their passengers without an injury being sustained, as was happily also the case with all the Irish railways. We therefore arrive at the inevitable conclusion that, notwithstanding the terror inspired by a railway accident, the rail is really by far the safest mode of locomotion with which the travelling public have ever been made acquainted.

ELECTRICITY AND TELEGRAPHY.

IT has been reported during the last few days that the honour of baronetcy is about to be conferred upon Professor Wheatstone for his numerous inventions and their great practical value. The invention of the stereoscope, and, in a very great measure, the present position of telegraphy, are due to him. It will be recollected that he was associated with Mr. W. F. Cooke in introducing the needle telegraph, and telegraphy generally into this country. Since that time, he appears to have given his time and attention more to the study of electricity and telegraphy than to other matters, the result being the enormous practical advantage to the profession and to the public by the invention and adoption of many valuable instruments, and amongst them we may mention his balance, or, as it is generally known, "Wheatstone's Bridge," by the use of which testing resistances of various kinds have been so much simplified and made so accurate; his magneto-electric alphabetical telegraph, rendering signalling so easy that the veriest tyro can exchange communications with one equally unacquainted with telegraphing, an instrument that is so pretty and complete in its appearance that it usually forms an ornamental object in a merchant's office. Very lately he has introduced an automatic instrument for sending messages at a high rate of speed; his other inventions and practical applications of electricity are really too numerous to mention. We feel sure that any recognition of his valuable services will be looked upon by all as a suitable recompense for time spent in bestowing practical advantages upon the country, and that an honour conferred upon one so high in the electric world will be deemed an honour to the profession generally, of which he is, and we trust may long continue to be, so bright an ornament.

Mr. Latimer Clark is bringing generally into use a unit of inductive capacity which will be found of great practical advantage. Its value has, we believe, been determined by Mr. Fleeming Jenkin. It is contained in a small box, and consists of a number of sheets of tinfoil fastened on to thin sheets of talc, by means of a hot iron and Thomson's wax, in series like an ordinary condenser, sufficient being used to make up the required unit.

The Spanish Government have invited tenders for the construction and submergence of a submarine line from Spain to the Antilles—to Porto Rico, and to Cuba—with a further extension to Panama and Nicaragua, the tenders to be sent in by the first of February. One special clause is worthy of remark: the contracting parties are to deposit the sum of £20,000 as guarantee for the fulfilment of the contract, which must be completed within three years. We have seen the rise of several schemes for crossing the Atlantic, but few with so little to recommend them as the present one, and we do not think it will be taken much notice of by our submarine telegraph manufacturers. Is it not strange that this should take place almost simultaneously with overtures made by the Spanish Government to the United States for the sale of the islands of Porto Rico and Cuba?

We noticed in our summary the appointment of instructors for the Indian Telegraph Service; two such appointments have been made. Mr. Louis Schwendler, from the firm of Messrs. Siemens, and Mr. Lambert, who has been for many years an assistant to Mr. Latimer Clark. Mr. Schwendler has already left, Mr. Lambert follows in a day or two.

Colonel Robinson. R.E., the Director-General of Telegraphs in India, has just returned to India to superintend in person the many improvements he has been organizing since his stay in England. Amongst these improvements may be mentioned the appointment of gentlemen to fill the positions of superintendents, who by passing through a course of studies in physics, electricity, and practical telegraphy, prepare themselves for a final examination preparatory to being sent out. By this week's steamer six of these gentlemen leave for India who have been undergoing for some time this course of study, and have satisfactorily passed their examination, a result we cannot but feel due to their studying so much under a practical telegraph engineer. We feel quite sure that the plan of placing them under a well-known electrician and practical telegraph engineer is a step in the right direction, and we understand that the progress made by them under the care of Mr. Preece, to whom we allude, has been so satisfactory that it has met the approbation of the Director-General. Mr. Preece still has a number of pupils under him studying electricity at Southampton, in addition to which they are undergoing further instruction in chemistry and mathematics at the Hartley Institution, preparatory to their examination for the various appointments in the Indian service.

A suit promising to be of great interest has been commenced in New York; a bill in equity has been filed on the part of Horace B. Tibbits against Cyrus W. Field and others representing the New York, Newfoundland and London Telegraph Company. The original concessions for Newfoundland appeared to have been obtained for the plaintiff by Mr. Frederick N. Gisborne, and after constructing some works, until stopped by financial embarassment, agreements were made with the defendants, and the works finally carried out for certain considerations to Mr. Tibbits, which not being, as he states, fulfilled, he has brought this suit. The total amount of his claims may be stated to be, with interest added, equal nearly to one-half of the whole capital stock of the existing company.

We have an account from America of a late telegraphic feat there—speaking from Houston (Texas) *via* New Orleans, Washington, New York, Chicago, Salt Lake City, and Helena (Montana), a total distance of nearly five thousand miles. It is considered as a very remarkable performance, and the account states that the wires were in fine condition and the weather favourable!

PHOTOGRAPHY.

MR. WARREN DE LA RUE'S PHOTOGRAPHS OF THE LUNAR MOUNTAINS.—CLOUDS IN LANDSCAPE PHOTOGRAPHS. — THE LONDON PHOTOGRAPHIC SOCIETIES.—PRINTING ON COLLODION.—IMPROVEMENTS IN THE COMMON CAMERA.

THE experience gained by Mr. Warren De La Rue, F.R.S., during a course of many years, as to the best methods of photographing the moon and other astronomical bodies, has led him to the adoption of collodion salted with iodide of cadmium only, coupled with pyrogallic and acetic acid development. Mr. Hardwich, the standard authority on photographic chemistry, also came to the conclusion, in opposition to the opinion of many practical photographers, that when collodion free from organic reactions and very pure chemicals are employed, the greatest rapidity is obtainable with iodides, without any admixture of a bromide. Mr. De La Rue's pictures are taken by means of the mirror of his reflecting telescope at Cranford Observatory, the image of the moon being thrown direct upon the photographic plate by the mirror, without the intervention of any second reflector, as in the Newtonian telescope, to cause loss of light. But owing to the unequal refraction, and ever-varying currents in the atmosphere, the image of the moon will not keep still upon the collodion plate, but is always quivering more or less: hence the necessity of a very rapid process to take the picture.

As already stated, Mr. Warren De La Rue works upon sound principles, but for theoretical reasons we think he may not yet have attained the greatest possible rapidity in his manipulations. It is a principle in photography that solarization, or over-action of light upon the plate, may be counterbalanced by the employment of a stronger retarding acid in the developer, but the stronger the retarding acid, the longer must be the exposure. Thus, if solarized pictures are obtained with acetic acid in the developer, the substitution of citric acid is the remedy, but the exposure must be longer. This argument cuts both ways, because if a weaker retarding agent than acetic acid be employed, greater rapidity is the result, and a shorter exposure of the plate is necessary. Formic acid is a very weak retarding agent, giving excessive solarization when the plate has long been exposed to a bright light, so there is reason to suppose that formic acid instead of acetic acid in the developer will slightly shorten the time of exposure. Very little difference in time will be noticeable, but in instantaneous photography, as it is called, every fraction of a second saved in exposure is of value.

Mr. De La Rue's exposures may possibly also be further shortened by another method. In instantaneous photography, the colour and composition of the glass forming the lenses affect the results, for all glasses are opaque more or less, to a portion of the visible rays of the spectrum. The same difficulty besets photographic work with a reflecting mirror, for the experiments of Professor W. Allen Miller, F.R.S., show that polished metals do not all reflect the extra-violet rays so perfectly as they reflect the visible rays. For instance, he found that speculum metal and polished steel reflect exactly the same rays of the spectrum, and give spectra on a photographic plate of exactly the same length each. But he also found that speculum metal gave an intense image for one-half only of the length of its spectrum, whilst steel gave a more intense image than any other metal throughout the whole length of the spectrum of the light reflected from its surface. These results point to the conclusion that a steel parabolic mirror will enable a photograph to be taken more rapidly than can be done by speculum metal or silvered glass reflectors.

Nothing but experiment can decide the two points here raised, and the first is very easily tried. The common formic acid of commerce is very impure; it frequently strikes a purple colour when added to pyrogallic acid, and some samples of it have a tendency to cause fog. Hence the pure monohydrated acid, as imported from abroad, should be chosen; and as it acts injuriously upon the skin, it may be at once diluted with nine times its bulk of water. Ten minims of this dilute solution will act as a sufficient restrainer over three grains of pyrogallic acid in winter and two in hot weather. In instantaneous photography, the quantity of restraining acid added to the developer should always be as small as possible. Professor Miller's results could be very easily tested by polishing two small circular pieces of steel and speculum metal, each exactly the same size, and allowing them to reflect two beams of lunar light upon separate parts of a photographic plate for a few seconds. On applying a developer it would at once

Digitized by Google

be seen which plate reflected most chemical rays.

The lunar photographs are copied in an enlarging camera. Mr. De La Rue finds that the enlarged positives are never so good as the original negatives, some of the smaller details being always lost in the process. Mr. Dallmeyer is now specially making an enlarging lens, which he thinks will give a perfect copy. The best slabs of optical glass are not commonly used in photographic lenses, as perfection is less necessary for such purposes than for the object-glasses of telescopes. Mr. Dallmeyer has the reputation of being a good optician, and it will be interesting to see how perfectly he can make a lens, to enlarge to a given size, without any loss of detail, now that he has put himself to solve the problem.

At the last meeting of the South London Photographic Society, Mr. J. R. Johnson called attention to the necessity of photographing the clouds and natural atmosphere of a landscape at the same time that the view is itself taken. In the days of old, photographers rarely produced natural clouds in their pictures, because the sky requires far less exposure than is necessary to obtain all the details of the landscape below, and except with very quick processes, the operators were usually under the necessity of spoiling either the sky or the landscape, by wrong exposure, and the former alternative was always chosen. At last, photographs of great beauty, with natural clouds in the sky, appeared in the market, and had a great sale, since which time, natural clouds have become common in photographs, being usually produced by double printing, the landscape being printed first, and the sky afterwards, from a cloud negative. Mr. Johnson pointed out that the clouds and landscapes of such pictures are not always illuminated in the same direction, and are otherwise untrue to nature. He exhibited some beautiful natural clouds, taken by means of the V-shaped moving diaphragm in the pantoscopic camera, and announced his intention, at a future meeting, of showing how to alter the common camera, so that the natural atmosphere can always be taken at the same time as the landscape or building below.

At the last meeting of the Photographic Society of London, Mr. Spiller, F.C.S., of the Royal Arsenal, at Woolwich, read a paper suggesting the use of hyposulphite of ammonia in the place of hyposulphite of soda to fix photographic prints, stating that it is slightly more efficacious, and that such pictures are likely to be more permanent. Mr. James Glaisher, F.R.S., presided, and stated that he had been absent from many of the past meetings in consequence of illness. He also spoke of the death of M. Claudet, F.R.S., and announced that the council recommended that the vacancy thereby made in its ranks should be filled up by the son of the deceased gentleman.

There are three photographic societies in London, and it has often been suggested that it is a pity they do not unite into one, thereby acquiring more power and more spare funds to devote to the advancement of the science. These divisions are much to be regretted.

Mr. Sutton, editor of the Jersey "Photographic Notes," is now yachting off the coast of Brittany. He suggests an improvement upon the method of printing photographs on wet collodion, recently published in these columns, and recommends that after the positive is taken out of the bichloride of mercury bath, it should be immersed for a long time in weak ammonia before fixing with hyposulphite of soda. This, he says, gives a richer black colour to the picture. One of the advantages of taking pictures for this process of enlarging is that the original negative may be very small, so that when taking views out of doors the operator need be burdened with a camera no larger than an opera-glass. With short focus, small lenses, such as would be used in a camera like this, negatives may be taken rapidly enough to secure tolerably good natural clouds, but, except in sea views, the best effects will only be obtained when some radical alteration is made in the ordinary photographic camera, so that the sky shall always be exposed for a much shorter time than the foreground. Some such plan will probably be broached by Mr. Johnson at the next meeting of the Photographic Society of London, where he will read a paper upon "A New System of Landscape Work." At the next meeting of the South London Photographic Society, Mr. John Traill Taylor will read a paper "On a Lime Light Burner of the First Order, by means of which an Explosion is rendered Impossible, either by Accident, Carelessness, or Design." This title is somewhat long-winded, but it betokens an interesting paper.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

THE USE OF A MIXTURE OF GAS AND AIR FOR ILLUMINATING PURPOSES — ANOTHER ICE-MAKING MACHINE—AN INDELIBLE MARKING INK.

WE have before referred to the proposed use of the Drummond light for the illumination of public places in Paris, and to the process by which oxygen is procured for the purpose. The manufacture of the oxygen is indeed the chief difficulty in the way of the application, and the municipal authorities of Paris hesitate to regard the method of M. Tessié du Motay, which we have described, as perfectly satisfactory. In this state of affairs another inventor comes forward with a scheme for burning a mixture of coal gas and atmospheric air so as to produce an intense light. Every one knows that the ordinary flame of a Bunsen's burner is but faintly luminous. The particles of carbon are so rapidly consumed that their momentary incandescence which, according to the generally received opinion, gives luminosity to the flame, is not permitted. It is necessary, therefore, to introduce some other substance which shall be maintained at a white heat, and so furnish the light. M. Bourbouze employs for the purpose a roll of very fine platinum wire gauze, upon which he directs a large number of very small jets of the mixed gases. The combustion of these gives a vivid incandescence to the platinum, and furnishes light at a considerably reduced cost. The air, however, has to be supplied by a sort of blow-pipe apparatus, which complicates the matter; but, notwithstanding this, the inventor assures us that a great saving is made by the use of his invention.

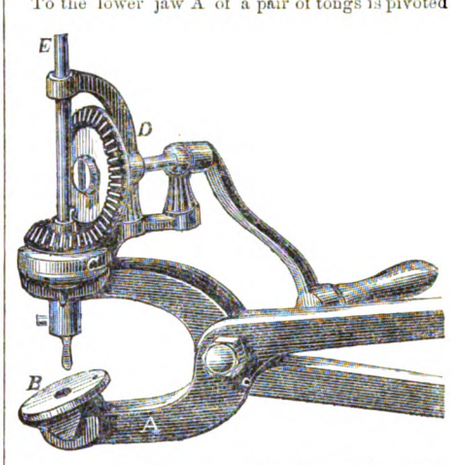
Another ice-making machine is described by M. Tellier, but it can hardly come into general use, although no doubt very efficient, since it involves the use of condensed methylic ether. This body at the ordinary temperature and pressure of the air is a sweet smelling gas; but, by great cold and by moderate pressure, it can be condensed into a colourless liquid. It is easily supposed that by the rapid evaporation of this liquid, when the pressure is removed great cold will be produced, and by proper arrangements, easily devised, large blocks of ice may be procured. The principal difficulty and cost will be the first production of a sufficient quantity of the condensed gas.

Dr. Jacobsen suggests the use of Lightfoot's aniline black for marking ink, which, on the score of indelibility, must possess some advantages over the ordinary nitrate or tartrate of silver ink. We give the author's receipts for two preparations. He first prepares a solution, No. 1, by dissolving 8·52 parts of crystallized chloride of copper, 10·65 parts chlorate of soda, and 5·35 parts of chloride of ammonium in 60 parts of distilled water. Another solution, No. 2, is made by dissolving 20 parts of hydrochlorate of aniline in 30 parts of water, and adding 20 parts of mucilage (one of gum to two of water), and 10 parts of glycerine. To make the ink, which must be prepared as wanted, one part of No. 1 solution is mixed with four parts of No. 2. The mixture will be of a dull greenish colour, and is ready for use at once. It can be applied either with a quill pen or with brush and stencil plate. The colour of the writing will at first be only pale green, but it will darken gradually on exposure to the air, or the black may be produced at once by employing heat. The best way of using heat is to hold the article marked over a vessel of boiling water, but the heat from a lamp or fire will of course effect the purpose. When the articles are washed with hot soap and water, the colour of the writing will be a dark bluish black. It will not be affected by dilute acids nor by alkalies. A strongish acid will turn it green, but an alkali will directly restore the black. A very strong solution of chloride of lime will first turn the colour red and finally discharge it, but only for a time. It will return again in a few days with increased intensity. The colour, in fact, can only be removed by destroying the fabric, which is more than can be said for the silver inks.

IMPROVED HAND DRILL.

THERE are frequent occasions in a machine shop where light drilling is required on work it is inconvenient to bring to the lathe. For this the Scotch or ratchet drill, if the job is heavy, is employed, and if light the breast drill. The placing and working of the former consumes considerable time, and the labour of drilling with the breast drill is excessive and exhausting. It is difficult also to hold the instrument so steady as not to cramp and break the drill. The combination of the drill with tongs and a pivoted bed piece, as seen in the engraving, which we take from the "Scientific American," obviates these objections.

To the lower jaw A of a pair of tongs is pivoted



a platten or bed B, having a hole through its centre, which is continued through the jaw for the passage of the drillings. The upper jaw is formed with a circular flange on which is mounted the circular or disc-like base C of the drill frame D. This, with the frame, is secured on the jaw of the tongs by means of two screw bolts—one seen in the engraving—passing through the jaw and screwing into the base of the drill. These bolts pass through semi-circular or segmental slots, by which the drill frame can be swung around at different angles to the tongs, to adapt itself to the convenience of the workman and the requirements of the work. If desired, the crank by which the drill is driven may be used on the upright spindle E. It will be seen that the pivoted base or bed B will allow the work to adapt itself always to the line of the drill.

In operation, the work being placed between the drill and platten, the left hand presses the handles of the tongs together, while the right turns the crank; the feed is thus graduated wholly by the pressure of the hand. This tool is the invention of Messrs. Nevergold and Stackhouse, of Pittsburgh, America.

AT the first ordinary meeting of the Society of Engineers for this session, held on Monday, the 20th inst., Mr. W. H. Le Feuvre in the chair, the following candidates were balloted for and duly elected as members:—Messrs. R. F. Fairlie, J. T. Chappell, Henry Gore, Lieutenant-Colonel Henry Wray, R.E., and Mr. George Spencer. As associates, Messrs. James Knox, Edward Harlock, and C. W. Salmon.

SOCIETY OF ENGINEERS.

THE first ordinary meeting for this session was held on Monday last, Mr. W. H. Le Feuvre, the president for the past year, in the chair. Premiums for papers read during the year were presented to Mr. S. W. Worssam, jun., for his paper on mechanical saws; Mr. A. Rigg, jun., for his paper on heavy guns; Mr. J. Gresham, for his paper on the injector; and Mr. E. Matheson, for his paper on the quality of iron. Mr. Baldwin Latham, president for 1868, then took the chair and delivered the following

INAUGURAL ADDRESS.

It is with mingled feelings of pleasure and anxiety that I enter upon the duties and responsibilities of the important office of President of this Society. It gives pleasure by reason of the honour conferred upon me, which I assure you I feel deeply; but I also feel some anxiety as to the results of my term of office. We have just terminated the most successful year in the annals of the Society, and I succeed, in the duties of the office of President, a gentleman who has devoted a larger amount of time to the affairs of this Society than usually can fall to the lot of a professional man to give. It is my intention, so far as lies in my power, diligently to discharge the duties imposed upon me; and I earnestly solicit your hearty co-operation and support. On an occasion like the present, I know it is expected that the President of this Society should give an address upon some subject associated with the objects of the Society. Year by year the task becomes more difficult, but on this occasion it is my intention, after having drawn your attention to some matters of passing importance to our profession, to speak to you of the results that have been attained from the prosecution of the sanitary works that have been carried out in the towns of this country. At the present time we cannot be unmindful of the position in which our profession is placed, the period being marked by the almost total suspension of public works. The present condition of things may not be without its lesson, and the time may not be unprofitably employed in taking our bearings and ascertaining our position, in order that in future we may steer clear of the rocks and quicksands of speculation. Engineers are, in a measure, responsible for the present position of affairs; and every engineer should know that the success of great public works is due, not only to the care and skill which have been displayed in the design or execution of the works, but also to the financial results of the enterprise; for unless public works, of whatsoever character or description, are made to pay, the employment of the private capital employed in their construction will be diverted into other channels.

In the railway system of this country we have an immense capital employed, but, unfortunately, at the present moment this description of property is at a discount, and there is a want of confidence in the public mind in all public works, arising, in a great measure, from the financial disclosures of the condition of some of the railway companies of this country; for when we know that upwards of 600 millions of money have been authorized by Parliament to be raised for the railway companies of the United Kingdom, and that probably upwards of 500 millions of the money have been actually raised in the shape of ordinary capital, preferential capital, debenture stocks, and debenture loans, we cannot but see that any commercial panic or failure of the system, tending to deteriorate the value of the property, must be attended with an immense amount of inconvenience and loss to the country. In a great measure the present financial position of some of the railway companies of the United Kingdom is due to the influence of Parliament in encouraging a rivalry that has led to the construction of many unprofitable works and to the deterioration of others. The conduct of Parliament with regard to the legislation on railways appears to have been most incongruous; at one period the committees report against the possibility of maintaining competitive schemes; on another occasion powers are given to increase the capital of existing companies, and, after all, schemes are sanctioned that tend to divide the traffic and divert the legitimate profits of the original undertaking. All the great works in this country that have been established with the sanction of Parliament should have their interests protected; at the same time, judicious regulations as to the limitation of profit and as to the general management of the concern should be imposed, which would give the public those advantages which are supposed only to accrue in the face of competition—competition often ruinous, and which is ultimately terminated by failure or combination. It cannot but be seen that the opening of upwards of thirteen thousand miles of railway in the United Kingdom, apart from the capital employed in their construction, has given an immense impetus to the trade and commerce of our country; moreover, the works of this character have not been without their influence in increasing the value of property throughout the kingdom. The knowledge of these simple facts will, at no very distant date, lead, it is to be hoped, to the resumption of operations whereby the benefits of our great railway system may be further extended; and, when this day does come, we shall be the wiser and more able to meet its requirements; in the mean time we must direct our attention to other works, and so provide employment for the industrial classes of this country.

With our railway system has sprung up that system of electric telegraphy which has been so generally adopted and usefully employed throughout this country. This branch of engineering has received very great attention, and has reached a high degree of excellence. The completion of the Atlantic cable, the successful measures taken in grappling for the original and broken cable in deep water, are now facts of history; but we well know that the news of the success attending the various operations of laying the cable sent a thrill of joy through the veins of every true citizen. We rejoiced with those who had successfully linked the New and Old Worlds; we felt thankful that their skill, industry, perseverance, and enterprise had been rewarded with a success that marks the event as an era in history. The present period is a critical one for those who have devoted their attention to the telegraph system of this country; for it is not impossible that Parliament, in the ensuing session, may be asked to adjudicate upon a measure by which the telegraph system of the country may be handed over to the Post Office authorities. It is thought by some persons that, by combining the offices of the telegraph and the postal arrangements of the country, a great reduction of expenditure will accrue, and that, therefore, the cost of forwarding telegrams will be reduced. We cannot but see that the proposed measure is one of those steps tending to centralize power in the hands of Government, and it may have the effect of stopping the efforts of private enterprise; therefore, a measure of this kind, although it may be attended with some advantages, yet, as it may tend to cramp the spirit of enterprise of the country, it should be carefully watched by those interested in the development of all public works.

The past year has been signalized by one of those international exhibitions of the industry and commerce of the nations of the earth. The late Exhibition of Paris differs somewhat from the former Exhibitions, inasmuch as an attempt was made to render the visitor conversant, not only with the products and state of the manufactures of different countries, but likewise with the habits and customs of their inhabitants. Exhibitions of an international character were inaugurated by our own countrymen with a view to stimulate the trade of the country, by inducing a spirit of rivalry and competition, which would lead the manufacturers to vie with each other in advancing and perfecting our arts and manufactures. The International Exhibition of Paris of the past year cannot be studied without giving a lesson to the manufacturers of our country; for we saw in it how closely we are being copied and followed in those manufactures that mark the modern progress of science, and that we have a task to undertake if we hope to maintain our supremacy and sway the commerce of the civilized world. There are those at the present day in this country who believe that, unless immediate steps are taken to avert the calamity, our manufactures are fated for destruction, and our commerce doomed to perdition; and who look to the little progress made by our country, between the Exhibition of 1862 and that of last year, in support of their views. It does appear that the short time that has elapsed between these Exhibitions is not sufficient to throw out in strong contrast with other nations the improvements and advances that we, as a nation, have made; but, if we take a longer period, dating from the Exhibition of 1851, of which the late and lamented Prince Consort spoke prior to its formation, "as a new starting-point from which all nations will be able to direct their future exertions," we shall be enabled to see that we have been moving forward in the march of human progress.

In chemistry important discoveries have been made; amongst others, those beautiful colours known as the aniline series have been produced. Hydrocarbon oil distilled from coal is manufactured on a large scale. The art of photography has been extended until it is become of infinite service to every branch of art and manufacture. The fine arts of painting and sculpture have not been surpassed. Electric telegraph communication has become oceanic. Magneto-electricity has been adapted and used for illumination of lighthouses, The manufacture of iron has been improved, and steel is now made by one process. The art of ship-building has made great strides. The appliances and munitions of war have been perfected. Economic appliances in connection with steam power have rapidly advanced. Greater attention has been paid to the value of human life, and the conditions best calculated to preserve its integrity. Steam power has been successfully applied to the cultivation of the soil. Numerous inventions have been patented tending to abridge and facilitate labour. The old established manufactures of the country have been improved, and new industries have arisen, which have a vitality that promises long endurance. The wealth and commerce of the nation have increased.

Although it must be clearly seen, when viewed through the long vista of time, that we have progressed and are still progressing in our arts and manufactures, we cannot lose sight of the fact that foreign nations have advanced fasetr than we have. They started in the race with a place far below us, and are now treading closely on our heels, and even now compete with us in our own markets for works requiring engineering skill and knowledge, as can be seen from the returns of the exports and imports of our country, which show that the value of the exports of raw and unmanufactured iron has year by year steadily increased, while our exports of machinery have decreased, and the imports of manufactured iron and steel into the country have increased. We find that Austria, Belgium, France, Prussia, and Switzerland are the nations that have made the greatest progress; and these are the nations, by a singular coincidence, which have paid the greatest attention to the education of their populations. The art of learning has been fostered by them, and has grown up and developed itself simultaneously with the development of the manufactures of those empires. The foreign workman is taught the principles that govern his every-day operations; and, by the aid of his theoretical knowledge, the successful copying of English designs, and the use of English tools, he has been able to develope and advance his particular manufacture in his own country; and so an impulse has been given to foreign industries, that we, in this country, only realize by the startling results. It cannot be gainsaid that the English nation have displayed in a greater degree than any other nation talent for inventions and all the energy and enterprise necessary for success; and therefore, if we develope and cultivate the intelligence of our citizens to the same extent as in foreign countries, we shall never be beaten in the great race of human progress. We, as a nation, must remove every obstacle to the progress of our people; we must teach our workmen applied science, which will give them confidence in the development of improvements; above all, we must teach them to emulate those truly great men who have risen by their own exertions from lowly positions to be the brightest ornaments of our profession, and whose memories still endure in all that perpetuates the memory of men on earth—in the offsprings of their genius and in the respect and homage of mankind. We cannot be unmindful of the fact that, in order to secure the result we hope to bring about by the means of technical education, we must place labour and capital in closer relationship, and must adopt measures that will put an end to strikes and lock-outs. The combinations of capital against labour, and labour against capital, must come to an end. The restrictions of trade societies compelling men to work with an average ability must be removed. Labour, like trade, should be free, and having all the blessings of liberty it will expand and progress.

We will now consider briefly the results of the sanitary works that have been carried out in this country. History teaches us that in remote periods works of drainage and water supply were considered necessary, whenever men congregated together in large masses; hence we find that the oldest cities of the world were sewered and well supplied with water. But then came a period in history, when the benefit of sewers and abundant supplies of pure water appear to have been forgotten, or at least ignored; when sanitary science, like many other branches of science, descended to the very lowest ebb, only to be revived in its

Digitized by Google

true spirit within the memory of living man. In our own country, the evils arising from retaining decaying animal and vegetable substances in the vicinity of our dwellings, and in some cases in our habitations, was patent to the early sanitary reformers. Year after year the fearful scourge of epidemic and endemic diseases, and the clear and unmistakable warnings of the cause, compelled Parliament to pass that measure known as the Public Health Act, 1848, the aim and object of which was to maintain and improve the state of the public health of the country. No sooner was the measure passed, than a large number of towns took advantage of it; and there are now about 650 towns and districts in this country that are governed in their various sanitary operations by that Act and its subsequent amendments. The sanitary laws of the country are intended to promote the adoption of such measures as are calculated to secure the health of its citizens. Pure air and water must be considered absolute necessaries, if life and health are to be maintained. The crowding together of masses in the cities, towns, and villages of our country naturally leads to the production of much offensive matter, which, if retained in the midst of our populations, will vitiate the atmosphere and poison the water supply; and the human body, robbed of its life-giving elements, is poisoned by the emanations of its own creation, and soon becomes the victim of disease and death. The modern works of sewerage and water supply have been experiments made for the purpose of improving the state of the public health, and that they have accomplished the end for which they were inaugurated will be seen by the following table, containing the results in twelve towns:—

Name of Place.	Population in 1861.	Average mortality per 1,000 before construction of works.	Average mortality per 1,000 since completion of works.	Saving of life per cent.	Reduction of typhoid fever rate per cent.	Reduction in rate of phthisis per cent.
Banbury	10,238	23·4	20·5	12½	48	41
Cardiff	32,954	33·2	22·6	32	40	17
Croydon	30,229	23·7	18·6	22	63	17
Dover	23,108	22·6	20·9	7	36	20
Ely	7,847	23·9	20·5	14	56	47
Leicester	68,056	26·4	25·2	4½	48	32
Macclesfield	27,475	29·8	23·7	20	48	31
Merthyr	52,778	33·2	26·2	18	60	11
Newport	24,756	31·8	21·6	32	36	32
Rugby	7,818	19·1	18·6	2½	10	43
Salisbury	9,030	27·5	21·9	20	75	49
Warwick	10,570	22·7	21·0	7½	52	19

It will be seen at a glance that the sanitary works which have been carried out in these towns have had a marked effect in staying the ravages of disease and death, and of prolonging the average duration of life, in those towns that have adopted proper measures. By reference to the last column we see that a great reduction has been made in the number of deaths from that painful and lingering disease that is so fatal in our country; which is an unlooked-for success, and is probably due to the drying of the soil by works of sewerage. How much society loses annually by preventable diseases it is impossible to fully estimate, as health is so intimately connected with all the branches of every-day life. We know full well that the power of physical ability forms the basis of all descriptions of labour, and that the full value of work cannot be got from a sickly, and therefore feeble population; therefore those communities that are in bad sanitary condition are considerable losers. The national prosperity of the country is impeded by the undue amount of sickness we have to support, and the losses of human life we have to sustain. If, upon no other than economic grounds, it is true economy to spend some little of our earnings in the prosecution of sanitary works. An estimate of the probable result of the value of sanitary works can be propounded in this way:—1st. The saving in the cost of funerals, inclusive of mourning and fees, which may safely be set down at £5 each. 2nd. The saving, by reason of the escape from sickness, with its cost, and the value of lost labour; and it may safely be taken that, for every life saved by sanitary works, twenty-five persons escape sickness, and that £1 per case would represent a moderate value of the result. 3rd. The value of the labour saved to the country by prevention of premature death. For every adult female 5s. per week, and for every adult male 10s. per week, or a mean of 7s. 6d. per week, may be taken as the value of the labour over and above the cost of maintenance. Taking a town in this way, and comparing the result with the expenditure that has been incurred in providing the means by which these results have been obtained, we shall see at a glance the result of sanitary operations. We will take, for the sake of example, the town of Croydon, in connection with which many of you are aware I have laboured for some years:—

EXPENDITURE IN CROYDON.

Purchase of freehold lands	£50,000
Construction of waterworks	70,000
Construction of sewers, sewage irrigation works, public baths, abattoirs, and general improvements...	75,000
	£195,000

The average mortality of the town of Croydon for seven years previous to the construction of sanitary works was 23·66 per thousand; and for thirteen years since they have been in operation it has been 18·64 per thousand, showing a saving of 5·02 per thousand per annum. The mortality in the year 1848 was 28·16 per thousand, and in the year 1867, 16·6 per thousand; in 1848, the population was 19,380; in 1867, it was 50,750, showing that the population increased 160 per cent., and the death rate reduced 40 per cent. between the extreme periods. The mean population for thirteen years since the works have been completed and in successful operation, commencing with the year 1855, has been 37,375. By taking the mean saving of life of 5·02 per thousand, and multiplying it by the mean population in thousands, and again by the number of years, we get 37·375 by 5·02 by 13 equal 2,439 lives saved. Of this number, six-tenths, or 1,463, would be adults, or persons above the age of twenty years, and probably one-tenth would be infirm from age; by making this deduction, we have still 1,317 lives, in the full vigour of life, saved. By using the figures before quoted in connection with the lives saved, we shall get the money value of the benefits conferred by the works:—

2,439 funerals, &c., saved, at £5 each...	£12,195 0
2,439 by 25 equal 60,795 cases of sickness prevented, at £1	60,975 0
1,317 value of labour, at £19 10s. for 6½ years	166,828 5
	£239,998 5

These figures show that in Croydon, in the short space of thirteen years, a sum exceeding by 25 per cent. the total expenditure for all purposes has resulted from the prosecution of the sanitary works. Although it has been here attempted to put a money value on life, we feel individually that life is priceless, and that we may look to the 2,439 persons saved from the jaws of death in this town alone as the living testimonies of the great value of sanitary works.

It cannot but be seen that the case has been understated. The averages do not give the full saving, when the population increases rapidly, and the scale of mortality as rapidly declines; and, moreover, it should be considered what would have been the probable increase in the death rate if the original state of affairs had been allowed to continue to the present period; for an examination of the mortality tables, prior to the existence of sanitary works and the efforts of sanitary labour, shows a gradual increase. With all the benefits that have been conferred by the prosecution of sanitary works, it cannot be overlooked that the first efforts of our sanitary reformers have been marred by reason of the state of pollution of the watercourses and rivers of the country. The growing evil of the system has found a remedy in the application or the liquid sewage to land; and, by a natural process, those foul streams that taint our rivers and water supplies may be turned from a course of destruction into a channel that will add to the material wealth of the nation. The results of sewage irrigation, as it is termed, are marvellous. Large and luxuriant crops are produced, while the foul streams are converted into comparatively pure water. The following analyses will show the result: they are by Doctor Oddling, a result of samples taken every quarter of an hour for twenty-four hours on the 23rd and 24th of November last. The sewage at the time was flowing over thirty acres of land, on which it had been continuously flowing for about two days; the volume of sewage passed on to the area in the twenty-four hours was 3,274,300 gallons, and the effluent water, flowing off after purification, was 2,245,200; so that 31½ per cent. of the whole volume was lost by evaporation and absorption. As the land was completely saturated prior to the experiments, it may fairly be taken that 15·75 per cent., or one-half the entire loss, is due to evaporation through the plant and from the water surface. This would tend to condense any impurities that remain in the effluent water in the proportion of the reduction of volume. In the analyses given, the result that would be obtained by condensing the water supply is shown in the third column:—

	Water Supply of Croydon. Average of the wells, Nov. 1867. Analysis by Dr. Oddling.	Sewage of Croydon after purification by irrigation, Nov. 1867. Analysis by Dr. Oddling.	Water Supply of Croydon condensed to some extent as sewage.
	Grains per gallon.	Grains per gallon.	Grains per gallon.
	21·777	26·180	25·233
Total solid residue	21·409	25·025	24·807
Mineral matter	·368	1·155	·426
Volatile matter	1·454	3·400	1·684
Chloride of sodium.....	·032	·042	·037
Ammonia	·026	·032	·030
Nitrogen as ammonia	·243	·419	·281
Nitrogen as oxides.....	·002	·144	·0023
Nitrogen as organic matter.			

A comparison between the second and third columns will show how nearly the sewage has returned to the state of the pure water as supplied to the town. It may be observed, that the total amount of organic and volatile matter contained in the effluent water after passing over the land is less than the average amount contained in the water supplied by any one of the existing London water companies; and, therefore, it may safely be laid down that sewage after such purification is fit to be turned into any fresh watercourse. It may be remarked, that the analysis of the sewage was made at a period of the year very unfavourable to the system. We must all have seen that as the process of applying sewage to land has become successful in effecting the purification, doubts have arisen as to the probable effect of spreading large volumes of it over areas in the immediate vicinity of populous places. The result of the application of sewage to land, in a sanitary point of view, is equally assuring, for we find, upon examination, that Norwood, which has its irrigation area close to an inhabited district, during the three years the sewage has been applied to the land, has had a mortality of 18·17 per 1,000 in 1865, 15·13 in 1866, and 14·21 in 1867; while the same area, but inclusive of more distant localities, has had during the same period, the respective mortalities of 21·26, 20·04, and 16·60, so it appears that, in the rapid growth of the plant, the assimilation of nitrogenous and carbonaceous matter, and the elimination of large volumes of oxygen by the plant, we have the antidote for what otherwise might prove baneful in its effects.

NEW METHOD OF CONSTRUCTING AND PACKING SLIDE VALVES.

BY MR. N. W. WHEELER.

FIG. 1.

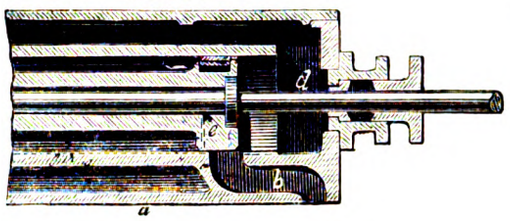

FIG. 2.

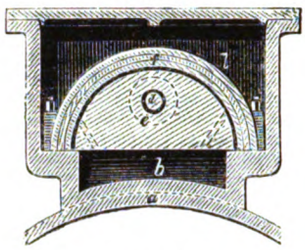

FIG. 6.

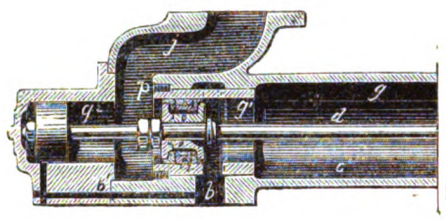

FIG. 4.

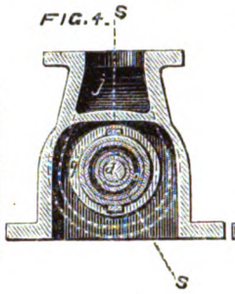

FIG. 5.

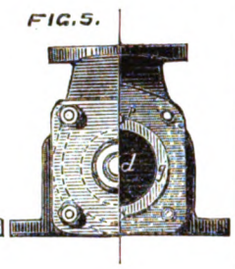

FIG. 3.

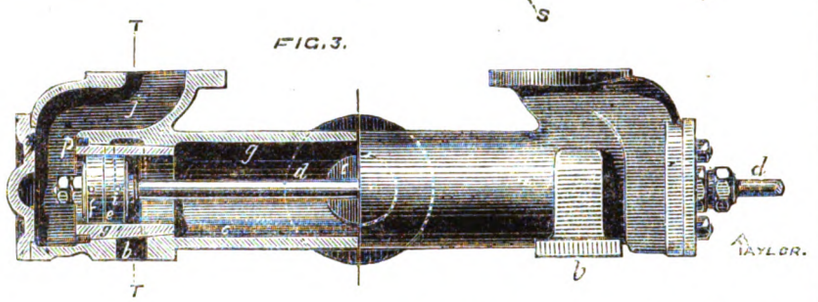


CONSTRUCTING AND PACKING SLIDE VALVES.

THE accompanying engraving illustrates a system of constructing and packing slide valves which has been patented here by Mr. N. W. Wheeler, of Brooklyn, U.S. Fig. 1 is a longitudinal section of a part of a steam chest fitted with a half piston or valve; fig. 2 is a cross section of the same; fig. 3 represents a steam chest fitted with a piston valve, the left half being a longitudinal section, the right half a side elevation; fig. 4 is a cross section of the same on line T T in fig. 3; fig. 5 is an end elevation of the steam chest, the left half having the cover on, the right half the cover off; fig. 6 is a longitudinal section on line S S representing an additional detail.

Piston slide valves have been considered by theorists the best valves known for steam engines; they probably would be so were it not for the difficulty of mechanically adjusting the packing rings to meet the peculiar requirements of their functions. In all examples that have come to the knowledge of Mr. Wheeler, the packing rings have been set or compressed against the sides of the valve cylinder by springs or other means by a constant energy. Now when the valve covers only a part of a port which is taking steam, so much of the surface of the piston as is not covered by the surface of the valve cylinder is pressed inwards by the action of the steam, and if the springs be not so strong as to cause a great amount of friction, the ring must yield to such pressure and allow steam to pass the valve into the exhaust chamber. This difficulty has instigated the trial, in many partially successful instances, of methods of setting the rings by rigid mechanical arrangements, whereby the valves while in use were in effect solid and unyielding pistons or discs, and only adjustable while less hot than when in use, and not capable of accommodating themselves gradually to the gradual wear of the parts.

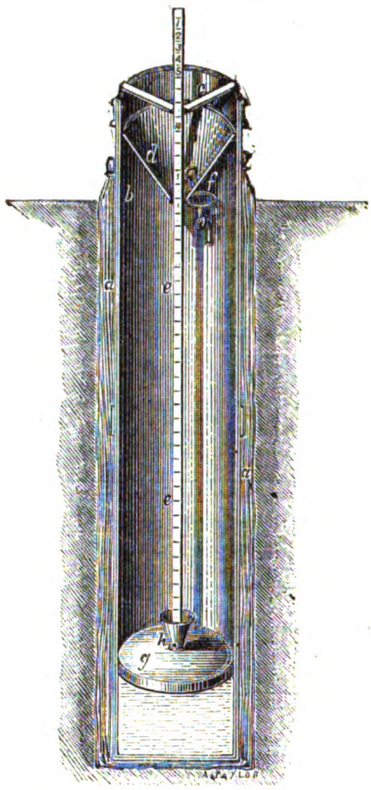
In the examples before us *a* is the steam cylinder; *b b* the steam ports; *c c* the exhaust way; *d d* the valve rod; *e e* the piston valves; *f f* the packing rings; *i i i* small ports leading from the exposed valve faces into the space within the rings *j j*, the live steam passages *g*, the valve cylinder which is seen in figs. 1 and 2 as a semi-cylinder *l l*. When the engine is in motion the valves *e e* have a reciprocating motion longitudinally with their axes over and across the ports *b b*, and when either valve is delivering steam to the engine steam passes into the corresponding port and presses the rings inward; or in the example figs. 1 and 2 presses the valve up against the semi-cylinder *l l*, but at the same time steam passes into the spaces *o o* inside the rings and neutralizes this pressure. When the exhaust takes place the valve is in such position (see the left in fig. 3), that the steam flows out of the ports *i i* and relieves the internal pressure at the same time that the external pressure is relieved. Thus if the valve pistons be fitted with ring springs, or the rings fit the valve cylinder by their own elasticity, in the same manner as is usual for working pistons, the rings will have for all the time not requisite for the lap of the ports *i i* the effective pressure only of the springs against the sides of the valve cylinder, and will accommodate themselves to the varying expansions and wear of the valve cylinders in a more perfect manner than analogous devices have hitherto been made to do.

In figs. 1 and 2 the valves having a solid face and being backed with packing rings, the rings are made in halves or such parts of a circle that their ends may fit fair upon the valve face, the semi-rings being riveted together near the ends, and the cuts distributed properly around the semi-circle. In the construction and use of piston valves, especially in the case of these, which are provided with periodical steam packing behind or inside the rings, experience has shown that the bridges across the port for the cuts of the rings to traverse are necessary, and that it is difficult to bore the valve barrels truly cylindrical if the ports are made in the barrel before it is bored; and, further, that the aberrations occur chiefly upon the surfaces of the bridges. Of course, if the barrels are not true the valve rings will not fit tightly in all positions, and there will occur a loss by leakage, and the friction will be increased. For the sake of truthful work, Mr. Wheeler bores out the chamber to fit a tapered bush g^1, which is in turn fitted by turning and grinding to the chamber, and secured tightly by the half-and-half threaded set bolts *p p*. The bush is then easily bored true, and the ports cut afterwards, leaving the bridges true with the other parts of the barrel. The work is greatly facilitated, for the reason that the bush may be treated separately and no hand holes or caps to allow access at the proper points to cut the ports are necessary, as would be the case if the barrels were in one piece with the chamber.

Fig. 6 shows an attachment which is useful in some cases; for instance, when it is not desirable to construct the engine with a crank attachment. g^2 represents a small cylinder in one with the cap of the valve chamber, into which is fitted a corresponding piston attached to the end of the valve rod, and so proportioned that the steam port for the small cylinder will be covered by the piston as it approaches the end of its throw, so as to imprison the steam beyond it and form a steam cushion to arrest the movement at the proper point. At the opposite end of the valve chamber is fixed a corresponding piston and cylinder. The steam passages b^1 lead from the steam passages *b* between the valve and the working cylinder. Now, when the valve is thrown by means of a tappet, so far that steam will enter the working cylinder through one of the passages the release will have taken place through the other, and the steam pressure upon the respective small pistons will be equal to that in the respective ends of the working cylinder by reason of the communications through the small passages b^1, and the overbalancing pressure upon one of the small pistons will complete the throw beyond that made by the tappet, which must compress or cause the partial expulsion of the steam in one of the cylinders opposing its action until the release takes place.

RAIN GAUGES.

IN his excellent little work on rainfall, noticed by us last week, Mr. Symons describes a form of rain gauge, which we have reproduced, together with the inventor's description and remarks. It is one of a class known as float gauges, and its principles are readily seen from the engraving. The rain falling in the cylinder



b is obviously equal to that falling on any equal area of the surrounding ground, and as the cylinder is uniform throughout, the float *g* will raise the divided rod *e*, inch for inch as the rain falls. Evaporation is prevented by the float *g* nearly covering the water, and also by the funnel *d*. The measuring rod is sometimes attached to the float, and sometimes dropped in only when it is desired to know the contents. The former arrangement is objectionable, because directly the amount of rain in the gauge equals the semi-diameter of the funnel, the measuring rod stops some rain which should pass over the gauge, and conducts it into the gauge, thus unfairly increasing the amount collected. The rod *e* is detached, and only dropped into the cup *h* when an observation has to be made, the exact quantity being shown by the loose cross piece *c*, which cuts the rod at the true reading, viz., as shown, at 8½ inches. The rod, cross piece, and funnel being lifted out, the whole inner case, with the accumulated rain, is removed by the handles *f*, emptied, replaced, and the funnel being returned to its ledge, the gauge is ready for another month. It is 4ft. long and 8in. in diameter; the cylinder *b* is double, the inside one lifting out when it is requisite to empty the water, and the outer one being wrapped in straw *a*, covered with canvas saturated with gas tar—the object of these strong precautionary measures being to prevent the water from freezing and bursting the inside cylinder; a handful of salt is also thrown in after each time of emptying. By the joint action of all these frost-resisting schemes, they have

Digitized by Google

defied Jack Frost amid the Cumberland mountains, even in the severe winter of 1865-6. We are not aware of any gauge better adapted for rough usage in mountain districts than this. Its price, made by Casella, is very moderate, and it can hardly be read incorrectly by the most stupid, or ingeniously perverse, inhabitant of these islands. We think, however, that the gauge is somewhat too small; a larger one would prove much better in practice.

In the form of gauge just described, we have explained that inasmuch as the cylinder is of uniform diameter throughout, the float rises inch for inch as the rain falls. But showers often yield very small quantities of rain, such as one or two hundredths of an inch. This would be almost invisible on the scale just described, and therefore a modification has been introduced, in which the collecting area is twice, thrice, or more than that of the cylinder. In this case it is obvious that the float will rise two inches for one inch of rain, three inches for one inch, or more, as the case may be. These are generally perched on a pedestal, but Mr. Symonds says they cannot be recommended for several reasons. 1. They are too much above the ground. 2. They are too much exposed to sunshine. 3. The rods are always attached to the float. 4. The rods are very frequently broken. 5. Owing to the exposure of the cylinders, the water often freezes and bursts them. Mr. Symons found one, which by causes 4 and 5, had in its old age recorded 25 per cent. too little!

ENGLISH AND FRENCH NAVIES.

THE following letters, illustrative of the manner in which naval matters are managed in England and France, are from the "American Army and Navy Journal." They are particularly interesting to Americans at the present time, from the additional light which they throw on the subject of boards of survey, which it is now sought to establish in the States. This step does not appear to the taste of Mr. Isherwood, who has at present the sole direction of these matters. But that it is necessary we may infer from the following passage in the above journal. Says the editor:—"A board of survey would not be expected to build ships or engines, but to hold a rigid scrutiny over those who have charge of the several departments. The experience of the past would tell them that no more Monitors should be built that would not float, like the twenty-eight that were designed by Mr. Isherwood, and superintended by his chosen subordinates. They would negative such private contracts as have taken millions out of the public treasury, and, having found out the inefficiency of our present chief of the Bureau of Steam Engineering, they would call to their aid the best ability among the civil engineers of the country."

The writer of the first letter says:—At one period in our history, when the United States were comparatively remote and unknown in the great family of nations, our policy was shaped with a modesty becoming our circumstances; but now, by the westward course of empire brought into a more central, and by our late struggle a more commanding and influential position, our policy must necessarily change with our condition. One result of this must be the building up of a modern navy; and as we will always rely mainly on the militia or volunteer elements for its expansion, that navy, forming a nucleus merely of the force that would be actually employed in a naval war, should be as perfect in its conception and detail as the genius of the country can make it. Probably a more propitious time for a recast of characters and a change of scenes than the present never occurred. But who is to line out the plot or perfect the detail? Both in England and in France the navy is under the direct control of naval officers, or, in other words, its destiny is shaped by those who know it best, and who are most deeply concerned in its welfare, whose honour in time of war depends upon its efficiency, and who, consequently, are the most likely of all others to devote to its interests their time, talents, and strength. Uninfluenced by party feeling, alone undisturbed amid the ceaseless mutations of office, unshaken by political convulsions, they are the conservators of their own history, and calmly pursue even amid civil discord, one high and undeviating line of policy. The exact sciences afford no plainer axiom than that to such hands should be confided the administration of naval affairs.

In France, the Board of Admiralty consists of a president and seven members. The first office is filled by the Minister of Marine, who may be either an admiral or a civilian; the others by six vice or rear-admirals, one of them having the title of inspector-general, and one inspector-in-chief, a civil office for which we have no equivalent. In addition to the Board of Admiralty is a Board of Works (*Conseil des Travaux*) to which have to be submitted all plans, propositions, &c., relating to works, plans of ships, engines, guns, &c., for the navy, and pronounced by the Board before being presented to the Board of Admiralty for their final decision. After the Board of Works comes the various bureaus for the transaction of the business of the several departments, as navigation, light-houses, &c., somewhat like ours. The French system is almost perfect of its kind, and is conducted with great precision, nor am I aware that the machinery of their naval administration is so cumbersome, or so complicated, as to impede work. One thing is quite certain, that waste and peculation are rare, and if we are to judge from results, the French method has in its composition a large element of success.

The much-abused English Board of Admiralty presents a curious contrast to that of their neighbours and rivals, and, so far as I can learn, has no very clearly defined duties, and yet does everything. The two Boards are eminently characteristic of the two countries; one has produced a navy by force of science and skill, the other by dogged perseverence, and both are remarkably fine in their way. I was told by English officers that they could get nothing better to take its place were their Board abolished, and by all persons on both sides of the channel, the opinion was expressed that naval officers of experience must necessarily govern their navies if they were to exist at all. Judging from the records of history, it would seem to be one of the most natural and self-evident deductions of experience, that a commercial marine will always require in proportion to its extent a military marine for its protection, for, however pacific the character and policy of a people may be, they must perforce provide against the warlike and aggressive propensities of their neighbours, and the responsibility of such protection cannot be avoided, for according to the ethics of nationalities, a country is as deeply committed to the security of its commerce as to any other of its obligations. Who that compares our commercial statistics of 1857 with those of 1867 will not say we have paid the full penalty attached to a violation of this well-established law.

On comparing the powerful squadrons of England and of France, and their great naval depots with our own, it is impossible to close one's eyes to the fact that our naval establishment is not what it should be. Who can contemplate the partial ruin of our once transcendant commerce—a ruin wrought by one pitiful corsair—without lamenting that violation of sound principles, that pursuit of false economy, which kept our navy far within the limits of efficiency, for want of a proper board of survey? Still smarting from the scourge that enforced the lesson, it would seem that the present is the auspicious time for a wise and far-sighted policy to apply the dearly-bought knowledge in laying the foundation for a navy, which shall be commensurate with the great country whose flag it has the honour to bear. An attempt has been made to pourtray the characteristics of the two Boards of Admiralty—each a type of its respective country. Our national character partakes of both. We have the indomitable energy of the one, the science and organizing powers of the other. With the histories of their navies before, with their failures to warn, their grand success to instruct, we only need with our superabundant wealth of material, the master spirit to call into existence a navy which shall be superior to either.

Another officer, writing from England, says:—We are a long way behind England in our material resources, so far as our facilities for building steam engines are concerned. England possesses fine Government workshops for building steam engines, but in time of war she would rely mainly on the private establishments, which are on a large scale, and turn out the finest engineers in the world. Indeed, several of these establishments are actively engaged at this time in constructing engines for some of the heaviest class of iron vessels which have lately been ordered; also, at private establishments, and built on plans designed by the Board of Admiralty. One cannot but feel disgusted when going over these huge, clumsy-looking, iron-plated vessels of the English, to see their light and beautiful engines that propel them thirteen and fourteen knots an hour, and then to see how little speed can be got out of this beautifully-modelled ship, the ——, which has an engine with twice the necessary weight of iron, and boilers that take up nearly all the ship. It is a reflection upon our engineering skill that we should be so far behind the English in our public vessels, while we are so far ahead of them in our magnificent river steamers. All this is owing to the difference in the two systems. We have given up everything to a chief engineer without any practical knowledge, whose theories are laughed at by all the great engineers in this country.

They are entirely at variance with English practice, and do not satisfy the English mind, no matter how many books may emanate from the Steam Bureau to cheat the world. The British Government employs none but the best private workshops to build its engines, and the Board of Admiralty exercise the most rigid scrutiny over them while they are building. The Board of Admiralty call to their aid the best naval and civil ability to be found in the country. Every marine engine is set up on shore before it goes on board ship, and every part is made to work harmoniously before it is accepted. Such is the result of having naval officers at the head of naval affairs; the men who have to sail and fight these ships exercise a positive and intelligent control, in a matter where our line officers have nothing to say. They build engines for one third of what it costs in the United States, not because the prices are higher, but because we seem to have no fixed plans, but go on altering from day to day, frittering away millions on doubtful experiments.

THE LEEDS ASSOCIATION OF FOREMEN ENGINEERS.

WE have much pleasure in noticing the progress of the Leeds Association of Foremen Engineers—a society which is doing an important work, not only in promoting a better feeling between capital and labour, but also in advancing that technical education about which so much has been said of late. At the annual dinner of the institution (dinners are the things to consolidate those societies), the half-yearly report was read, and from it we glean the following particulars:—The report congratulated the members upon the position the association had attained during the comparatively short period of its existence. The want of such an association had been long felt, and on March 4, 1865, the society was formed by the enrolment of seventeen members, a number which had steadily increased, there being at present thirty-eight ordinary and seven honorary members. The members were required to be managers, foremen, or principal draughtsmen connected with the different branches of the engineering trade, the object being to afford facilities for promoting acquaintance and information amongst its members, the formation of a library of standard works on mechanical and scientific subjects, and for philanthropic purposes. The first two objects had been satisfactorily accomplished, and no less than ten papers on very important subjects—such as the clip pulley as applied to mines, the injector as an elevator, safety valves, the manufacture of iron, coal, the application of steam power on common roads, &c.—been read, all of which had evinced considerable skill and laborious research, and most of them had been illustrated by carefully executed drawings and diagrams. The discussions elicited by the reading of the papers were of the greatest importance, the members reading up on the subject, and criticizing freely and reasoning acutely. The committee urged upon the members the fact that it was only by close and careful study, especially in professional subjects, that they could hope to retain a right to the title of foremen in their various departments; and they expressed the hope that when any member was in doubt or difficulty on any mechanical or scientific subject, he would bring it forward at a general meeting, so that he might have the benefit of the experience of other members, if such information could be given without infringing upon any trade secret. The report concluded by alluding to the notion entertained by some persons that that was a trade society, and in proof that this was a misconception of the objects they had in view, the committee referred to the preface to the rules, where it was stated that the association did not, on any occasion, discuss the politics of the trade, that it had no secrets, but rather courted publicity; that its objects were purely and solely philanthropic and instructive, and that it essayed to assist its members in creditably filling the important posts confided to them.

HEAT WITHOUT COAL.

RECENT scientific discoveries should do much to lessen the alarm of those who fear the exhaustion of our coal fields. Mr. H. W. Pond, of Newark, U.S., remarks, in the "Mining Journal," that economists have speculated on the possible discovery of some method of producing heat independent of coal, and the decomposition of water has been regarded as a probable expedient. With our present knowledge and appliances it appears not to be difficult to realize this proposition, even in competition with coal—at least in a small way. The agents are obvious—wind-power, a magneto-electric machine, oxygen and hydrogen gasholders, and the electrolysis of water. The result would be that oxygen and hydrogen would be available for the production of the heat which would be required. For use in the arts the oxy-hydrogen furnace would, of course, offer advantages far above any other known, and results could be reached impossible with the lower temperature of the coal fire, while the flame would be free from deleterious substances common to coal. Owing to its gaseous form, and the intensity of its heat, this fuel would be manageable in many ways impracticable with coal. For instance, seams could be hard-soldered with great rapidity with the jet of the compound blow-pipe, and it is probable that the joints of steam-boilers could be heated for welding in a suitable oxy-hydrogen jet.

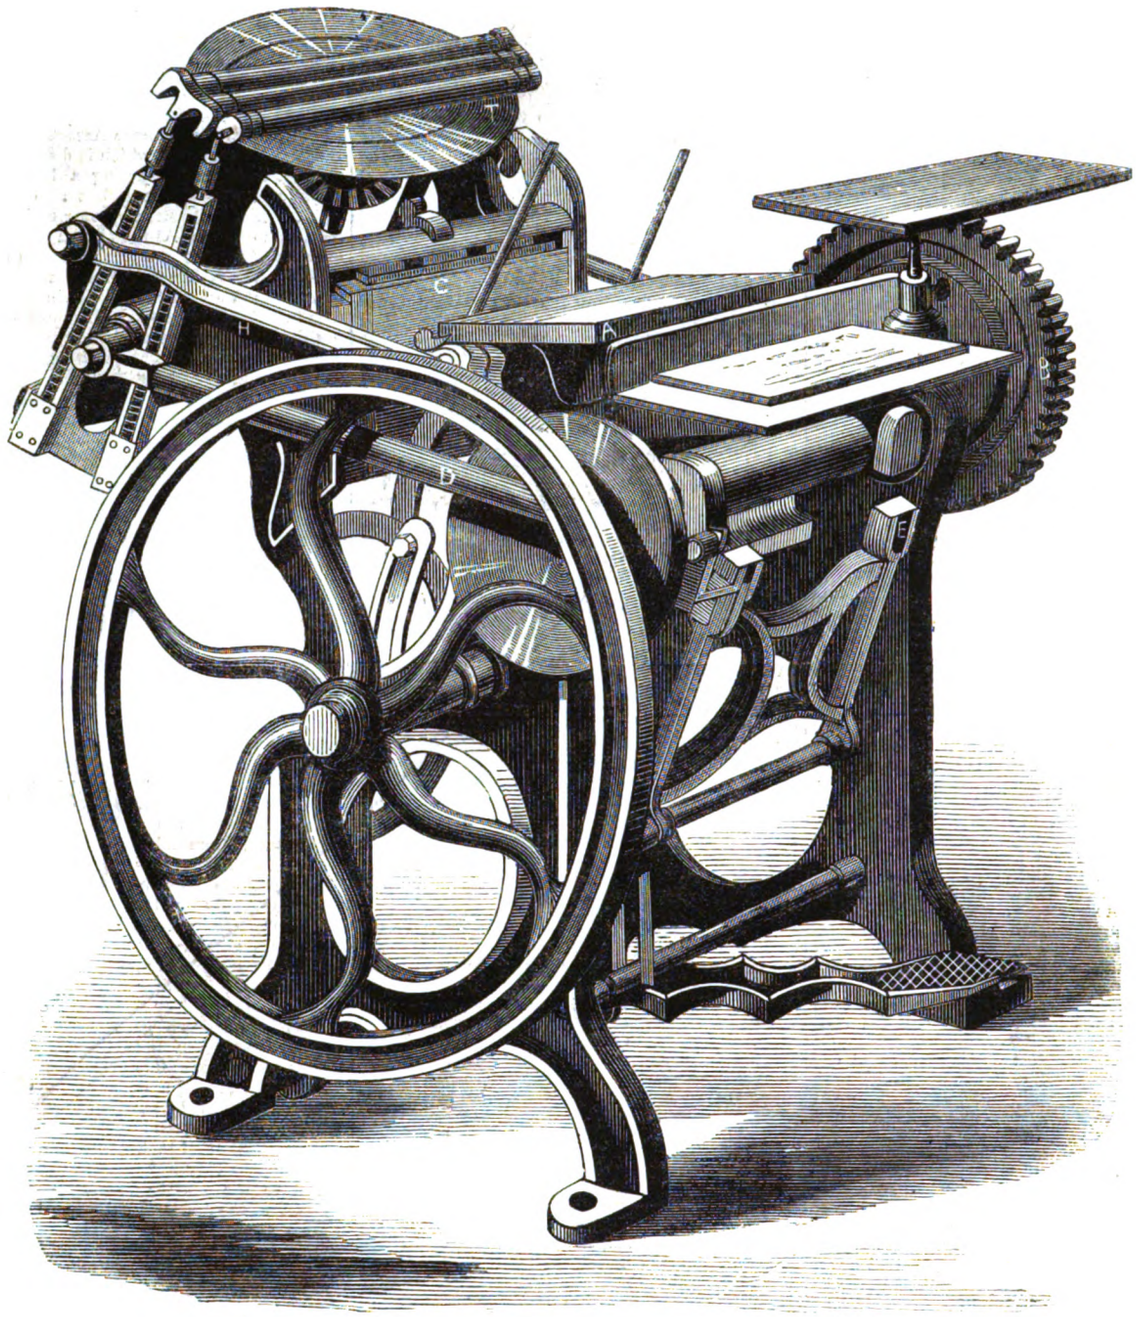
THE MINERVA PRINTING PRESS.

BY MR. CROPPER.



THE MINERVA PRINTING PRESS.

THE press illustrated above is specially designed for the execution of all that class of work ordinarily performed by hand in the platten press. It may be well to explain to such of our readers as are not acquainted with the process of printing, that two forms of presses acting on distinct principles are in use. In the simplest of these the type, locked up in an iron rectangular frame or chase, is fixed on a metal table, which can be traversed in V grooves like a plane table by a rack and pinion worked by the operator. The table being drawn to the front of the machine is inked by running a roller over it. The sheet to be printed is then placed on the "forme" of type, and pushed back beneath the platten, an iron horizontal plate worked up and down between guides through a small distance. The printer then takes the impression by pulling a horizontal lever, which operates very powerfully on the platten through a series of knuckle joints. This answers well where the number of impressions required per hour is limited; in other cases cylinder machines are employed. The type is locked up and placed on a sliding bed as before, but the pressure is applied by passing the forme under a large roller or cylinder, on which the paper is held by tapes for the time. As the paper is generally printed on both sides, two cylinders and formes are employed, the paper being passed over and under the cylinders from one to the other by an ingenious system of tapes. The whole is worked by power. The forme is inked by being drawn under a number of small inking rollers made of treacle and glue. In this way a very large number of impressions may be thrown off in a limited time, and the proper amount of pressure can be brought to bear on a large sheet which could not possibly be worked by manual power.

The Minerva press very ingeniously combines many characteristics of the two. It can be worked by either hand or power according to the size of the sheet. Its construction may be thus explained:—The platten, A, is operated upon by an internal cam on the spur wheel, B, and is brought into a horizontal position, as shown in the engravfng, to receive the sheet. It is then rocked upon its axis by means of this cam until it stands in a vertical position opposite the forme, C, when the forme is brought towards it to give the impression by means of the arms, D, on each side of the machine. While receiving the impression, the platten, or its counterbalance, is securely locked by the gate, E, so as to prevent the possibility of any movement of the platten by vibration or otherwise. This gate is operated upon by a surface cam inside the crank disc, F. The disc carries the axle of the crank arm, D, which rocks the back frame to and fro; the back frame carries the type bed and inking apparatus. The inking apparatus consists of two discs, which revolve in opposite directions, to ensure a more perfect distribution. The inking rollers receive their supply from the disc, to which a self-feeder may be applied if necessary, and are thence carried down over the type. These rollers are operated upon by the arm, G, which has a peculiar and novel motion not easily rendered intelligible. The rollers are held down to their position by means of elastic springs, and are thereby suitable for any size of type. The chase for the type is held by a screw and clip; it is perfectly secure and instantaneously removable. The sheet is withdrawn from the type by the "frisket" arms, which are operated upon by the cam and lever, H. For card printing there are two guides attached to the surface of the platten, one of which is operated upon by the cam, B, which allows the card to fall into a suitable receptacle after receiving the impression, so that the machine merely wants feeding, an operation which any lad of ordinary energy may perform at the rate of 2,500 to 3,000 copies per hour, working the machine with his foot. The engraving shows the manner of working. The press is open to receive the sheet; the operator puts on with the right hand and takes off with the left. He has perfect command over the machine

FIG. 2.

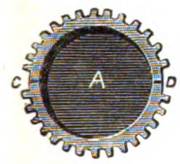

FIG. 3.

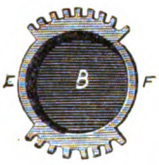

—sees the face of the type, the ink disc, the rollers, and all the working parts of the machine—without changing his position, and the printed sheet is presented to him face upwards, so that any imperfection may be instantly detected. The impression is adjustable by means of four screws and check nuts under the platten. As the platten is brought into a horizontal position to receive the sheet there is no danger of the operator being trapped, as in some other platten machines.

THE DUJARDIN TYPE PRINTING TELEGRAPH.

IT is now just three years since we placed before our readers particulars of the Dujardin type printing telegraph, and pointed out its advantages for overland lines.* We now illustrate some improvements in this apparatus, recently patented in England by M. Dujardin, whose address is 29, Boulevart St. Martin, Paris. These improvements consist, firstly, in a special arrangement of cross type wheels which being made to oscillate on one common axis will allow of printing at will either letters or figures; secondly, in an inking piston pad especially applicable to this system of cross wheels; thirdly, in a sort of electro-magnet as distributor of the printing currents; fourthly, in a system of governor for regulating the gear by which the transmittor is driven. These various improvements are represented in the accompanying engraving, in which fig. 1 is a plan view of part of the receiving apparatus provided with M. Dujardin's system of type cross wheels; these being fixed crosswise one on the other rock on their common axis, and are placed now the one now the other opposite to the paper strip, which always keeps the same direction.

A and B are two type wheels cut out in a ring shape; A is the letter wheel, and B the figure or other complemental mark wheel; A has at C D two apertures formed through both ends of one of its diameters; B has likewise at E F two similar apertures through the two ends of one of its diameters. The wheel B is made to enter the wheel A so that the apertures C E and D F may coincide. A and B are made to cross over one another, and are secured to each other by rivets. I J K L represent a metallic disc fitting exactly within the wheel B; this disc being placed within the wheel B two screw cut holes are pierced in its periphery through the apertures E F into which apertures are engaged headless screws G H where the cross wheels are pivoted. The disc is then so cut out as to only preserve a centre and two spokes, both centre and spokes constituting the rocking axis of the cross wheels. The cross wheels thus prepared are secured on the last mover axis of the clockwork, whereby the type wheels are rotated; a piece of steel O P serving as a stop to the cross wheels is screwed upon M N, and a double lever Q R is securely fitted in a slide formed in M and N. A connecting rod S is jointed to the double lever and the figure wheel; a horseshoe-like spring T is pressing on the two ends of the double lever so as to give the cross wheels proper steadiness.

With regard to the mechanism whereby the cross wheels are made to oscillate, A^1 B_1 represent the last axis in the clockwork which serves for printing; it makes a complete revolution at every time a type is printed; it carries an eccentric C^1 which through the connecting rod D^1 and the bell lever E^1 F^1 causes a to-and-fro motion being made by the rod G^1 H^1, which is elbowed at H_1, and terminated by a spring I^1. A pin J_1 fixed into G_1 H_1, and sliding in a groove formed in the knee K_1, serves to maintain G^1 H^1 in an invariable direction. When by means of the transmittor of the apparatus one of the double lever ends Q R is set in contact with the spring I_1, the printing action will cause the

* See MECHANICS' MAGAZINE for February 10, 1865.

Digitized by Google

cross wheels to oscillate in one direction until they are stopped by the piece O P, and vice versa.

In fig. 5 we have represented another device which M. Dujardin uses for procuring the oscillation of the cross wheels. *a b* is a flexible finger or pin effecting through the action of the printing gear a complete revolution at each time a letter or a figure is printed. Whenever through the transmitter one end of the lever Q R is set in contact with *a b*, the cross wheels will rock in one direction, and when the other end or side is set in contact with *a b*, the cross wheels will rock in the opposite direction. This system of cross wheels requires an inking pad which may work softly or by slight touch.

This inking piston pad is shown at fig. 2. It consists in a brass tube U, fig. 1, to the top side of which is applied a piece of velvet fixed thereto by means of an edge ring, and inside which enters a piston-like acting screw V. A thick leather washer X fixed by rivets to the mouth of the tube U serves as a female screw to admit the screw V. The pad is set on an axis on which it is free to rock; an adjusting screw Y and its abutment allow of the pad being brought more or less close to the type wheels, so that the nap only, and not the very fabric, can touch the wheels; a spring Z throws the pad on the type wheels. In tube U is put some cotton impregnated with an oleic ink, and by means of the piston V the ink is made to pass through the velvet gradually, and as wanted.

M. Dujardin's improvements also consist in a special electro-magnet distributor of the printing currents. We should here observe that the type wheels of his receiving apparatus are turned through the action of alternate positive and negative successive currents without any apparent intermission, and that the printing is produced by the breaking off of the line current corresponding to the letter or type to be printed. This special electro-magnet receives the line currents in the like manner as the electro-magnet or magnets of the type wheels. The rod of its pallet communicating with a local battery and abutting against two regulating screws, the one against which it is abutting during the attraction presents no peculiarity, but the other against which it abuts when the attraction subsides is isolated and communicating with the printing electro-magnet. The special electro-magnet is so disposed that its pallet during the whole time it is run through by the line currents may be attracted in a continuous or equivalent way, which prevents the local current from being conveyed to the printing electro-magnet. But when an interruption of the line current is taking place, the pallet rod attracted by a reacting spring, or by a counterweight, abuts against the adjusting isolated screw above mentioned, which allows of the local current being conveyed to the printing electro-magnet, so as to actuate the printing mechanism.

Two arrangements of this electro-magnet are shown in the annexed engraving, one being represented at fig. 6. A B is a vertical thin wire coil run through by the line currents. Inside the same is fixed a soft iron cylinder C D, terminated at its lower part by a soft iron washer E F. Another cylinder G H of similar metal, hollow and thinner than C D, is suspended above C D from the end of the lever I J oscillating round the point K; this lever is provided with a movable counterweight L, for which may be substituted a reacting spring; the end I of the lever is abutting against the adjusting screw M. The local current or printing current enters the lever I J at K, and is conveyed through the regulating screw to the printing electro-magnet. Now, when it is desired to set the type wheels in motion, the iron cylinder G H is drawn continuously by the cylinder C D, and the local or printing current is cut off at I M. When the line current is cut off, G H being no longer attracted by C D, the lever I J falls back on M; on the local current passing into the electro printer, printing is produced. As soon as the current is returned to the line, the local current is broken, and so on.

Fig. 7 represents the other arrangement of M. Dujardin's electro-magnet. A B is a thin wire electro-magnet run through by the line currents. The pallet C is very light, and so is its rod; it oscillates round the point D; E is its reacting spring; F is both an abutment screw, and an adjusting or regulating screw. The local current passes into the system through the support of screw F, and goes out therefrom through the support of the pallet C. When the type wheels are set in motion the pallet C is attracted continuously by the electro-magnet A B, and the local current is broken at F. When the line current is cut off, the pallet being no longer attracted, rushes on the screw F, and affords passage to the local current, whereby printing is to be effected. When the current has returned to the line the pallet C cuts off the local current, and so forth. The electro-magnet and its pallet may vary in their shapes and sizes indefinitely, which is unimportant, the main point being that the wire of the distributing electro-magnet, and that of the electro-magnet, by which are rotated the type wheels, can receive the line current in bifurcated ways.

The gear regulator or governor by which the transmittor is operated is represented at fig. 8. A B is the vertical axis gearing with the last mover axis of the clockwork; C D cross bar secured to the top of A B; E F vertical rods jointed to the ends of C D; G H are the axes of the jointings; I J metal balls fixed on E F; K L screw pincers secured on E F, above the jointings or articulations G H; M N pieces of leather held by the pincers K L; O P springs which may be given more or less tension by means of an adjusting screw; they serve to bring the rod E F close to one another. In the resting condition of the governor the leathers M N do not touch the circle which they are intended to rub upon; Q R pillars supporting a circle, S T serving as a support to circle U V arranged quite horizontally by means of three wedging screws. When the axis A B is allowed to rotate, its rotary speed increases, or is accelerated so far as the centrifugal force of the ball I J has become superior to that of the springs O P, when the balls I J recede from each other, and compel the leathers M N to rub on the circle U V, which prevents the rotary speed from accelerating any longer. The more the springs O P are bent, the more can be accelerated the rotary speed before the leather pieces M N can rub on the circle or hoop U V, and vice versa. By varying the weight of the balls I J, the march of the governor may also be regulated at various speeds. The circle U V needs no lubrication.

ROYAL GEOGRAPHICAL SOCIETY.

THE fourth meeting of the present session of this Society was held at Burlington House on Monday evening last, Sir R. I. Murchison, Bart., President, in the chair. The following new fellows were elected:—A. L. Elder; Dr. J. A. B. Horton; R. Jardine, B.A.; Eugene Morris; M. C. Morrison; A. H. Mounsey; G. Macnair; J. F. Pownall; J. Pender; J. B. Redman, C.E.; H. P. Stephenson; Dr. T. Staley, Bishop of Honolulu; T. O. Stock, M.P.; H. A. Tilley; Major G. H. Waller; R. Watson; and E. B. Webb, C.E.

Before the commencement of the ordinary business, the President read a letter respecting Dr. Livingstone, which he had received the same day from Dr. Kirk, of Zanzibar, dated 29th October; it ran as follows:—"I write now only to assure you that nothing further has reached us regarding the traveller in the Lake Regions, who must, without doubt, be Livingstone, since we have news of him from Quilon as having been seen west of Nyassa, where gold is found. Bunduki, the native to whom the letters were given, has not yet reached the coast, being delayed, as we hear, by carrying ivory in double journeys from village to village; and he is still too far off to make it of any use sending men to receive the letters which he has in his possession. It will be some time before we can write to Johanna, but I hope that Moosa and his companions may be well watched, and, when the time comes, severely punished for the misery they have caused. They, however, press their claims for salary, and have even sent men here, in the hope of getting their wages paid."

A paper was read on Explorations in the Isthmus of Darien, by M. Lucien de Puydt. The author, in this memoir, gave the scientific results obtained during two expeditions he had made, in 1861 and 1865, into the interior of the isthmus, having for object the discovery of a practicable line for a ship-canal from ocean to ocean. He first directed his attention to the routes followed by Captain Prevost, Mr. Gisborne, and others; ascending the river Savannah, and crossing to the confluence of the Rio de la Paz and the Chucunaque, acquiring the conviction of the impossibility of constructing a canal in this direction towards Caledonia Bay. The statements made by Dr. Cullen on this subject he ascertained to be completely erroneous. He found, moreover, that the altitude of 152 metres—on which was built a host of projects for a canal—was founded on an erroneous reading of the tables of Colonel Codazzi, the New Granadian surveyor; this altitude being given as that of a village on the road and not as that of the greatest height of a pass in the mountains. M. de Puydt afterwards turned south, and ascended the Tuyra River as far as Paya. The broken nature of the Andean chain there gave him hopes of finding a low pass; and he returned to Europe, organised a new expedition, and penetrated the isthmus again in 1865, from the side of the Atlantic. With three companions and a party of eleven labourers he entered the river Tanela, north of the delta of the Atrato, and sending away his vessel to cut off the retreat of his men, he opened a path through the forest, and on the 25th of August discovered a break in the mountain chain, having an altitude of only 120ft. above the level of the sea. His observations for heights were taken by measuring the velocity of current of a river which flows from the pass to the sea. The memoir included interesting details on the orography, ethnology, &c., of the isthmus.

The President observed that the paper gave a well-written and attractive description of a country very little known to geographers, and that the author's enterprise was carried out with a gallantry deserving of all commendation. In so far as related to the course of the Tanela River, and the depression in the chain, the geographical facts communicated were new.

In the discussion which followed, Mr. G. W. Hemans, C.E., disputed the accuracy of the means employed by M. de Puydt for the determination of the altitude of the pass. Captain Bedford Pim stated that should the line examined offer facilities for a ship-canal, the construction of one could not be carried out in the face of a treaty concluded on the 26th of August last, between the Government of New Granada and the Panama Railway Company, by which the former bound itself not to concede to any one the right to construct a railway or ship-canal west of a line which would include the Pacific terminus of M. de Puydt's project.

A second paper was read "On the Physical Geography of the Belize River," by Mr. S. Cockburn: an account of the extent of the Belize River-basin, the rainfall, evaporation, and so forth, over the area.

The President announced that an exploration of the Belize region, of some interest to geographers, had been made by Lieutenant Cooper Abbs, of the "Doris" frigate, an account of which had been that day communicated to the Society.

PEAT FUEL.

THE great difficulty encountered hitherto in the utilizing of peat for purposes of fuel in Ireland has arisen from the existence of the large quantity of water which the bog-land contains. By a system just invented by Mr. Hodgson, a member of the Irish Institute of Engineers, this obstacle to success appears to have been removed. Mr. Hodgson uses a tube of iron 5ft. long and 4in. in internal diameter, at one end of which a hydraulic ram works. The tube is filled with the peat to be operated upon, and at each stroke of the ram a cake one inch thick is produced, the peat in the tube being at the same time pushed forward an inch. As each cake requires about a minute to traverse the length of the tube, there are 60 cakes produced at the time. Numerous experiments have proved that a tube of this description, worked by a ram, will produce 100 tons of compressed peat weekly. In order to make the peat serviceable for fuel, it is necessary that the tube be supplied with dry turf. This is obtained by using the upper surface of the bogs, which, having been exposed for a few hours to the atmosphere on a fine day is rolled slowly over iron plates, heated only by the waste steam of the compressing machine. By this treatment the turf is rendered sufficiently dry to face the tubes, and it has been ascertained that by the combustion of 25 tons of compressed fuel, power and heat enough can be obtained to dry and compress 75 tons of excellent peat. It has been further computed with a tolerable degree of certainty that eight acres of bog-land are sufficient to yield during fine weather some 5,000 tons of compressed fuel. The cost of production, as far as it has hitherto been ascertained by experiment is, for 400 tons per week, 3s. 11½d. per ton, exclusive of the expense of management. The total cost of production cannot be more than 5s. 10d. or 6s. per ton, and as the peat has been sold for 9s. a ton at the works, and for 11s. 6d. in Dublin, a considerable margin is left for profit.

THE POISON OF THE COBRA.

OUR readers will recollect that some interesting experiments have lately been made in India relative to the action of the poison of the cobra by Dr. Shortt. This gentleman, having regard to the numerous lives that were lost annually in India from the bite of this snake, was mainly anxious to discover some antidote for its poison, and set about testing its various remedies in repute for that object. After much expense, and no little risk to himself, he has found that all are valueless. Still thinking that some effective agent might be known to the natives, he offered a reward of 500 rupees for its production, stipulating that he (Dr. Shortt) should find the cobras and conduct the experiments, which were to be three in number. The prize still remains unawarded. Recently Dr. Shortt has received a communication from Sir T. Madava Row, the Dewan of Travancore, intimating that his Serene Highness the Maharajah has taken much interest in the question, and begs to offer a reward of 1,000 rupees, under such conditions as Dr. Shortt may think desirable, to the person who can produce a remedy, and satisfy him that it is effectual against snake bite. The prize, therefore

Digitized by Google

now amounts to £150. The discoverer, whoever he may be, will serve the cause of humanity greatly; and this announcement, we hope, will awaken an interest in the question that may lead to some satisfactory result. Dr. Shortt has been good enough to say that he will be glad to facilitate the conduction of experiments (or to receive any suggestions thereon), and that he will consign to the "Lancet," for the use of any gentleman disposed to investigate the question, heads of cobras, uninjured, preserved in spirits or simply dried, or in any other way that may be desirable; and, should it be advised—the idea is exceedingly unpleasant, but if science demand we must obey—he will send one or more cobras themselves for experiment, on being fully satisfied that every precaution will be taken to prevent the likelihood of any accident occurring. Certainly never were conditions more favourable for experiment, ugly though it may be. We therefore hope the result will be the discovery of an antidote to a poison which kills so many human beings every year.

The "Madras Times" observes that Dr. Shortt's challenge will doubtless call forth Indian specifics from all parts of the country. We would recommend to him a trial, if possible, of those remedies which the South American Indians practise in their gloomy and snake haunted forests. For every vegetable poison and for every snake poison—and they are many—which exist in the forests of Brazil, it is asserted there is a vegetable antidote growing close at hand, and it is to be regretted that when Mr. Clements Markham introduced his chinchona trees into India he did not endeavour to procure a few of these boasted South American plants which are said to cure the most venomous bites. The experiment would have been worth a trial, and may yet be tested.

SCIENTIFIC EDUCATION.

IN order to assist the artizan classes who may show an aptitude for scientific instruction, the Committee of Privy Council on Education have resolved to aid local efforts in founding scholarships and exhibitions. The scholarship is intended to maintain the student while remaining at the elementary school, and the exhibition to support him while pursuing his studies at some central institution where the instruction is of a high grade. The local scholarships are of two kinds, the elementary school scholarship and the science and art scholarship. With regard to the first, the Science and Art Department will make a grant of £5 towards the maintenance of a deserving student to the managers of any elementary school who undertake to support him for one year and subscribe also at least £5 for that purpose. The grants will be made from year to year on the condition that the student each year pass in a new subject or in a higher grade of the same subject in which he first passed. It will be for the locality to determine for how many years the student may hold the scholarship, but in no case can he be allowed to hold it for more than three years. With respect to the science and art scholarship, the Science and Art Department will make a grant of £10 towards the maintenance of a student at an elementary school, who has taken a first grade in freehand or model drawing and elementary geometry, and passed in one of the subjects of science. The Department will also make a grant of £25 per annum to the managers of any school or educational institution, or any local committee formed for the purpose, who will raise the like sum by voluntary contribution for the maintenance of a student at some college or school where scientific instruction of an advanced character may be obtained. The exhibition may last for one, two, or three years. The conditions under which these grants will be made may be obtained from the Science and Art Department, South Kensington.

ALLEYNE'S PUDDLING FURNACE.

PUDDLING furnaces offer a wide field for improvements to the practical man. Of this stamp is Mr. J. G. N. Alleyne, of the Butterley Iron Works, Derby, whose invention has reference more particularly to puddling furnaces having rotating beds, and consists in an improved arrangement for keeping these beds cool. For this purpose the bed is made of wrought iron, and is supported centrally either directly by the vertical shaft from which it receives rotary motion, or it is carried by means of a wrought or cast-iron cylinder fixed on a turntable upon the vertical shaft, the inner part of which cylinder has a communication by means of pipes or air tubes with the outer part, to allow of the circulation of the air and water jets.

Our engraving shows at fig. 1 a sectional elevation of a puddling furnace with a rotating bed, and at fig. 2 a sectional plan on the line X X of fig. 1. A is the bed, constructed of wrought iron, and provided with a lining of fire-clay, slag, or other material. This bed is supported upon a wrought-iron cylinder B fixed on the turntable C, carried by the shaft D, and by rollers E at its circumference. A slow rotary motion is imparted to the shaft D, and through this to the turntable C and furnace bed A, by a worm F and worm wheel G. Between the bottom of the bed A and the turntable C, and surrounding the cylinder B, is an annular water trough H, carried by the girders I, in which a continuous circulation of cold water is maintained by means of the inlet pipe J, and the overflow pipe K. To the outer circumference of the bed A is fixed a cylindrical flange L, passing down as shown, and having fixed to it a second flange or rim M projecting over the outer edge of the trough H, and dipping into the water. A second cylindrical flange or rim N is fixed centrally to the under surface of the bed A, which flange also dips into the water in the trough H.

By this arrangement, while the flanges L and N are free to revolve with the bed A, they form, by means of the hydraulic joints, an enclosed air-tight space surrounding the entire outer surface of the bed

FIG. 1.

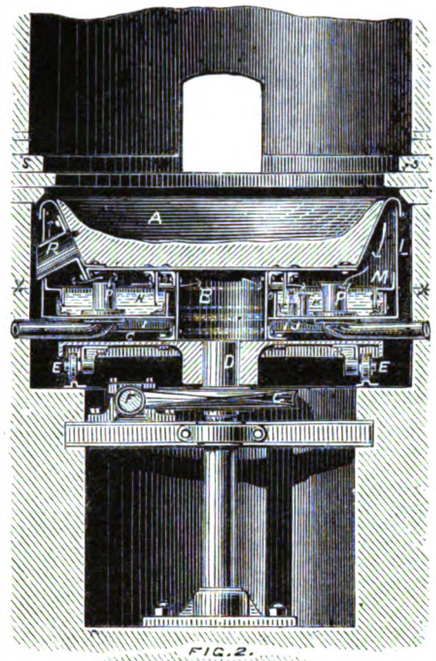

FIG. 2.

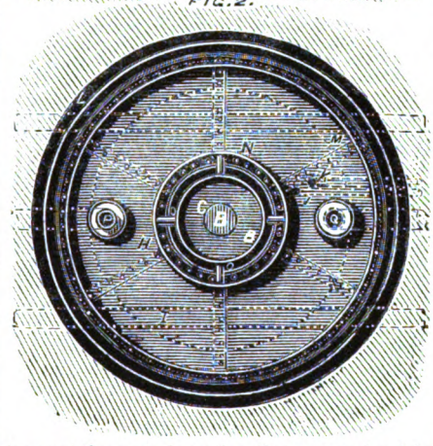


A except the central portion, that part enclosed by the cylinder B being, however, put in communication with the air-tight space by means of pipes O O. A pipe P passing through the trough H projects into the enclosed space below the bed A, through which pipe air is forced by means of a fan into the space, a jet of water entering such pipe being at the same time made to mix with such air in the form of spray. This mixture of air and water spray, in circulating in the space, passes in contact with the under surface of the bed A and very effectually absorbs the heat therefrom, and then passes away through a second pipe Q as indicated by the arrows, the escape of the air being, if necessary, accelerated by the application of an exhaust fan to the pipe Q. R is a spout to the bed A passing through the enclosed space for running off fluid slag or metal when required. The brickwork S of the furnace is made to project over the edge of the rotating bed, in order to protect it as much as possible from injury.

Mr. Alleyne's apparatus has been in use at the Butterley Iron Works for some time, and has made over 250 tons of iron. Mr. Alleyne first commenced working in June, 1866, with the machine applied to an old puddling furnace without a revolving bottom, the machine being arranged to turn on its centre and by a self-acting motion to move across the whole bottom of the furnace. It was arranged to turn from the bridge to the flue and work all the iron on the bottom in two minutes. By this arrangement it was found that the quantity of coal ordinarily used for 4 cwt. of metal melted and worked 10 cwt. It would have worked more, but the capacity of the furnace was limited, and it boiled over. Although only on an experimental scale, 10 cwt. heats were actually worked. Mr. Alleyne next put up a furnace worked by the same machinery with a rotating bottom, kept cool by the spray jets. This rotating bottom was made to work in an ordinary furnace. This self-acting, vibrating, or rather oscillating motion was disconnected, and the machine worked beautifully. The bottom was necessarily limited in size, but 5cwt. heats were worked, the apparatus for cooling the bottom and all the driving gear acting most satisfactorily. The waste on the average of the last month's work with this apparatus was 1cwt. 2qr. 16lb. per ton, being lower than the average of the whole works, and only using the same quantity of coal on 5cwt. as the ordinary furnaces did for 4cwt. Mr. Alleyne is now taking down this rotating bottom and putting up one to hold a ton, which will be worked with the same quantity of coal as is now used for 8cwt. We understand that this system works very well with puddled steel, as it stirs the iron so vigorously and steadily. In puddling by hand, the puddler cannot do this when the mass gets pasty; some parts are decarbonized too much and others not enough. With the machine, however, perfect uniformity can be attained. We may certainly pronounce this invention to be a practical success.

THE SILICATED CARBON FILTERING TAP.

THERE are various methods of obtaining pure water; by some it is filtered in the cistern, and by others it is purified after having been drawn. But these means are not within the reach of all; in fact, those who as a rule are obliged to use water of the greatest impurity, are just those who can least afford to pay for such methods of rendering it wholesome. Now, however, they can do it by using the silicated carbon filtering tap, which is just the thing for the proprietors of small tenements in poor localities to have fixed to their cisterns. The filtering medium is placed in the front part of the tap, which is removable. To clean the tap (which may be done without running off the water), it is only necessary to unscrew the front part and blow strongly through it. By this means all the impurities are brought to the surface of the filtering medium, and may be washed off before replacing the tap. Upon sanitary grounds it is impossible to over-estimate the advantage of thus being able to obtain a supply of pure water in a poor district, where the water is exposed to every kind of contamination. We would therefore draw the attention of the medical officers of such districts to this simple and efficacious preventive of disease. As we have referred to filters, we may here mention that an improvement has lately been introduced by the Silicated Carbon Filter Company, of Church-road, Battersea, London, in their filters. They use india-rubber instead of cork for the sockets of the taps, and thus prevent leakage of water from the softening or cracking of the corks, an evil which all filter users will be glad to see remedied.

Correspondence.

THE SQUARE OF THE CIRCLE. AND THE GREAT PYRAMID OF GIZEH.

LETTER VIII.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

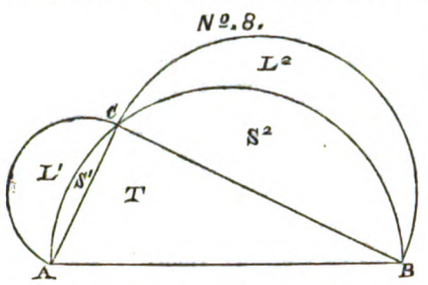
SIR,—In reply to the interesting letter of your correspondent, Mr. S. R. Bosanquet, in your issue of 27th December ultimo, the following extract from "Hutton's Philosophical and Mathematical Dictionary," 2 vols., 4to, London, 1815, will show to him and to your readers in how far there is a relation betwixt my discovery that the square of the circle is four-fifths of its tangent square, and the discovery of Hippocrates, of Chios, of the quadrature of the lune, respecting which Mr. Bosanquet correctly and properly quotes the argument of Aristotle:—

"Though the quadrature of the whole circle has never yet been effected, many of its parts have been squared. The first of these partial quadratures was that of the lune or lunule, given by Hippocrates, of Scion or Chios. The lune of Hippocrates is this. Let A B C (diagram 8) be a triangle right angled at C, and semicircles be described on the three sides as diameters; then the triangle T (A B C) is equal to the sum of the two lunes L^1 and L^2. For the greater semicircle is equal to the sum of the other two. From the greater semicircle take away the segments S^1 and S^2 and there remains the triangle T; also,

Digitized by Google

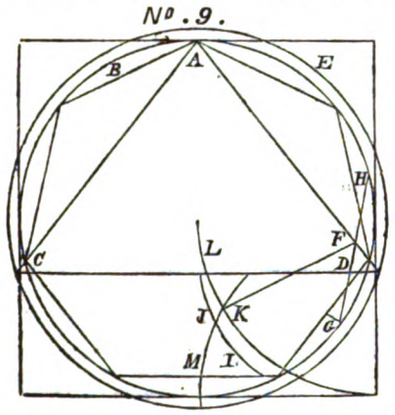
from the two less semicircles take away the same two segments S^1 and S^2 and there remains the two lunes L^1 and L^2; therefore, the triangle T is equal to the two lunes L^1 and L^2." The same demonstration is given in Montucla's Great Mathematical History in French, where, in vol. 1, the first and second diagrams are in elucidation of the quadrature of the lunule by Hippocrates.

In referring Mr. William Hayden, in reply to his letter of 21st December ultimo, in your issue of 3rd



current, to my letter No. VII., which appeared in the same issue, as to what may result from his perseverance in proof of the truth and value of my discovery that four-fifths of its tangent square is the strictly accurate area of any circle; I would only urther remark that if he will look back to my letter No. III,, in your issue of 18th October ultimo, he will observe that he has made a somewhat disingenuous and unacknowledged use—perhaps unwittingly—of my own diagram No. 7, in his last diagram as well as formerly.

I now go on with the result of the evidence contained in Colonel Howard Vyse's record of the measurements of the angles and lines of the Great Pyramid of Gizeh, quoted in my last letter. I, therefore, draw attention to the accompanying diagram, No. 9. It will there be seen that the exterior



lines of the Pyramid, viz., its base and sides, form a physical representation of the major part, or four-sevenths of the ancient "diatessaron" or perfect fourth in music, which was considered the only perfect or complete harmonious illustration of infinite symphony. Hence the antique myth of the music or motion of the spheres or planets placed by the ancient Egyptians as follows:—1, Saturn; 2, Jupiter; 3, Mars; 4, The Sun; 5, Venus; 6, Mercury; 7, The Moon; and our own musical gamut of seven notes or tones. The "diatessaron" is described by Hutton as "the perfect fourth, or a musical interval, consisting of one great tone, one lesser and one great semitone; the lengths of the strings to sound the 'diatessaron' are as 3 to 4." The sides of a perfect pyramid proceed as in diagram 9, from its apex in the zenith angle at A of the inscribed heptagon of the circle B, each over two-sevenths, or taking both sides, four-sevenths of the circle B, which may be assumed to represent a sphere. Passing through that circle in the angles of its inscribed heptagon at C and D, the side lines reach the base of the pyramid on the circumference of the circle E. The circles B and E represent relatively the annual circles of revolution of the moon and sun, that of B being the lunar year of 12 months, and that of E being the solar year also of 12 months. The values of these circles are calculated on the true ratio of the diameter to the circumference discovered by me, and explained in my letter No. IV., in your issue of 25th October last, viz.:—diameter 5, circumference 16; and the unit of measurement is the whole breadth of the Grand Gallery of the Great Pyramid, viz., 6ft. $10\frac{1}{4}$in. British. This is the grand unit of measurement of all parts of the Pyramid, as I shall afterwards show; and in these two circles by its means are represented relative periods of revolution of $354\ \frac{36708}{100000}$ days and $365\ \frac{25}{100}$ days. In order to explain my meaning here I have been obliged in some measure to anticipate the facts of my subsequent letters. But without going further into those, it will be already clear to your readers from the given measurements in the angles and lengths of the base and sides of the Great Pyramid that there is no other possible geometric explanation of them than that I have now, I believe, adduced for the first time and theorized from, viz., the lines given in the stated manner by the equilateral heptagon inscribed in a circle, and when applied to a pyramid is a sphere. And if it has been hazarded on many previous occasions that the Great Pyramid is one of the pillars of Sothis or columns of Hermes which Plato travelled from his Athenian home to Egypt to see, and to learn astronomy and geometry from, at the hands of the Egyptian priests, and, previous to him, on the same errand, Pythagoras; I am not aware that the astronomical fact of this Pyramid representing the old Egyptian luni-solar year, which was in use before the time of Osiris or Hyperion, has ever been pointed out in the manner of which I have now attempted a commencement, and which in following out in the interior of the Pyramid its further numerical relations are emphatically stamped.

In respect to the points to which I have already drawn attention in this wonderful structure, I think it not out of place to quote what (putting aside for the time what the Greek and Roman historians say) one of the oldest known reliable authors relates on the objects of its builder, as well as the remarks of one of our cotemporary and most distinguished philosophers after his receipt of Colonel Vyse's measurements of 1837.

Masoudi, who died in the 345th year of the Mahommedan era or Hegra, writes as follows:—"In the Eastern (the Great) Pyramid were inscribed the heavenly spheres and figures representing the stars and planets in the forms in which they were worshipped. The king also deposited the instruments and the 'thuribula' with which his forefathers had sacrificed to the stars, and also their writings; likewise the position of the stars and their circles." "There were different degrees among the priests who were employed in metaphysical speculations, and who served the seven planets. Every planet had two sects of worshippers, each subdivided into seven classes. The first comprehended priests who worshipped or observed seven planets, the second those who served six planets, the third those who served five planets, the fourth those who served four planets, the fifth those who served three planets, the sixth those who served two planets, the seventh those who served one planet. He (the king) filled the passages with talismen, with wonderful things and idols, and with the writings of the priests containing all manner of wisdom—the names and properties of medical plants, and the sciences of arithmetic and geometry, that they might remain as records for the benefit of those who could afterwards comprehend them. He ordered pillars to be cut, and an extensive pavement to be formed, &c." Notice will be taken of this extract when the objects of the Grand Gallery of the Pyramid are demonstrated. The other writer is Sir John Herschel, who was furnished by Colonel Howard Vyse with certain facts and measurements, especially the horizontal angle of the entrance passage, and the angle of the sides of the Pyramid with its base. Sir John Herschel's words in replying are—"The supposed date of the Pyramid 2123 years before Christ, added to our present date 1839, form 3962 years (say 4000), and the effect of the precession on the longitude of the stars in that interval having been to increase them all by the above named quantity (55deg. 45min.) of longitude, it will follow that the pole of the heavens at the erection of the Pyramid must have stood very near to the star, a Draconis; in short, speaking as in ordinary parlance, the entrance passage may be said to have been directly pointed at, a Draconis, at its inferior culmination, at which moment its altitude above the horizon of Gizeh (latitude 30deg.) would have been 27deg. 9min. No other astronomical relation can be drawn from the table containing the angle (26deg. 41min.) and dimensions of the passage. The exterior angles are remarkably uniform, but the angle 52deg. is not connected with any astronomical fact, and was probably adopted for architectural reasons." I shall offer some remarks on this passage also, when I proceed to sum up the evidence of the different measures of the Great Pyramid, to eliminate the entire theoretic significance which I attach to them as a whole astronomically and in connection with the Biblical seventh day as a day of rest and refreshment, of completion, of fulfilment and return. I only now observe that the entrance passage pierces the side of the Pyramid connecting two angles of the inscribed heptagon, at a point F, exactly 49 feet perpendicularly above the base of the Pyramid, by Colonel Vyse's measurements, where one of the sides of the inscribed heptagon G H cuts the side of the Pyramid. For reasons to be afterwards explained, the inscribed heptagon was multiplied by 4, and thus was produced 28 sides, of which the side G H is one. The length of the entrance passage is determined by the circumference of a circle I of equal diameter with the circle B, and the centre of such circle being advanced 1-28th along the circumference of the circle B. The angle of it is determined by its having to pass from the circumference of the circle I at J, through the point of junction at K of the two circles L and M, each equal to the circle B, the original circle having the value of the annual rotation of the moon in units of the whole width of the Grand Gallery of the Pyramid, as already expressed. In conclusion, it will be seen that the whole of the values of the angles, and lengths of lines of sides, base, and entrance passage of the Pyramid, depend upon the quality impressed upon the circle by the power of its inscribed heptagon. I ought to add that Colonel Vyse gives the length of the entrance passage when entire, from its entrance at the side of the Pyramid 49 feet perpendicular above the base of the structure to the level of the horizontal passage leading to the subterranean chamber hewn in the solid rock, as 343ft. 10in. British. I fear I have already trespassed sufficiently on your space. In my next I shall endeavour to complete the description of the lines and angles of the passages and rooms of the interior of the Pyramid already known.—I am, Sir, yours, &c., WILLIAM HARVEY.

London, January 22.

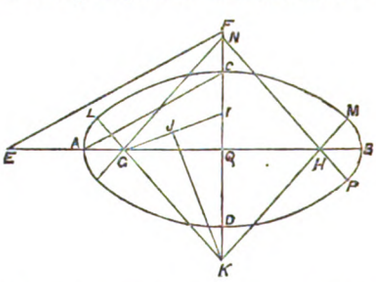
HEAT.

SIR,—May I request the insertion of a few remarks upon a subject upon which so many theories have been unsuccessfully brought forward. The subject is heat. As it is the key to the knowledge of the universe, a few observations upon a question of so much importance may not be unacceptable to your readers. It appears to me to be a subject that is beyond the grasp of the philosopher of the present day—the chemist. It eludes an analysis. Great in its simplicity, it is rejected by science. Nature exists but in unceasing change. Heat is the decomposition of mattter. Light is its modification. By this theory, and by this alone, can the phenomena of the universe be explained. The unceasing source of power that retains the planets in their orbits is at the expense of that orb which forms the centre of the system. In the constantly increasing magnitude of the planets increases also the distance from the central power, until such influence having become enfeebled they assume or reassume an active form, and become the centres of systems of their own. The two bodies from which we can form the most correct ideas are the earth and its attendant satellite. In the one we inhabit, what do we behold beyond (comparatively speaking) the formation of recent ages? An igneous rock, beneath which still glow the fires of a former system. And if we turn our eyes towards its satellite, where can we find a greater picture of exhaustion? A truer representation of a world burnt out? It is not my intention to enter further into a question of such magnitude in a communication such as this, my purpose being to draw attention to that which I conceive to be the key to the knowledge of our existence.—I am, Sir, yours, &c., H. SALOWAY.

6A, George-street, Dover-road.

METHOD OF DRAWING AN ELLIPSE.

SIR,—Having had my attention drawn to the subject of practical geometry by the recent correspondence in your pages concerning the circle, I beg to forward you a method of drawing any ellipse with common compasses, which was proposed by me in 1849. The figure produced is of course a compound one, made up of four arcs of circles, very pleasing to the eye; and I think the rule will commend itself as much to the geometrician for its comparative correctness, as it does to the mechanical draughtsman for its facility in practice. It is as follows:—Let



A B be any major axis and C D any minor; produce A B towards E, and C D towards F; make A E equal to C Q, and draw E F parallel to A C; then set off A G, B H, and C I, equal to F C; join G I, bisect it in J, and at J erect a perpendicular cutting C D (produced) at K. Next make Q N equal to Q K; and G, H, N, K will be the centres of the four circles required. Through G and H draw K L, K M, N O, and N P, all equal to K C; then the curve drawn through the points A, L, C, M, B, P, D, and O will be the ellipse required. I will have your readers to demonstrate the correctness of this method, and prove its utility or otherwise for themselves, observing only that the ellipse produced by it is not mathematically perfect, but is nearer the true figure than that produced by any other process I know of.—I am, Sir, yours, &c.,

Lee-crescent, Birmingham, January 9. JOHN CRANE.

FLOW OF WATER.

SIR,—I have a cistern 120ft. by 40ft. by 7ft., supplied by a water course with an inclination of 1 in 16 running 1in. deep. At the lower end I have an opening for letting out the water for use 7¼in. wide. When the cistern is quite full I find raising my sluice 1in. I get a sufficiency of water. Supposing there to be no waste, how long may I count on being supplied with a sufficiency; and what is the formula for working out this.—I am, Sir, yours, &c.,

Matale, PLANTER.

November 28, 1867.

[As you have not given the breadth of the watercourse it is impossible to calculate the rate at which your cistern is supplied, consequently the question resolves itself into the following. Given a cistern containing, as yours does, 218,400 gallons, the contents of which are let out by an opening 7¼in. by 1in., how long will it be before it is run dry. You should have given the exact height of the opening, but in absence of the precise data we consider the discharge to take place under a variable head, commencing with 7ft. as the maximum.

The formula to work by in this case would be

$$T = \frac{2A}{m S \sqrt{2g}} (\sqrt{H} - \sqrt{h})$$

where T = time in seconds, A = the area of the cistern, S = the orifice, H = the greatest head, h = the least, m = 0.60 and g 232.16. As the value of h is not given the discharge and the time it would occupy cannot be ascertained, unless it is assumed equal to zero. In the latter case, a fortnight would nearly empty your reservoir.]

GIFFARD'S INJECTOR.

SIR,—Will you be good enough to inform me in what volume of the MECHANICS' MAGAZINE the original description of Giffard's Injector appeared.—I am, Sir, yours, &c., W. H. M. ELLIS.

University Club, Dublin. January 22.

[Our correspondent will find a full description of Giffard's and other injectors in a paper read by Mr. Lewis Olrick before the Society of Engineers, and published in the MECHANICS' MAGAZINE for December 22 and 29, 1865. A further paper on the most recent improvements in the injector was read by Mr. Gresham before the same society at the close of last year, and will be found in our issue for January 3, 1868.—ED. M. M.]

PETROLEUM FURNACES.

SIR,—In your late remark on my apparatus for burning petroleum, that the boiler at Woolwich is not likely to be relit in its present state, you are quite right. I wish to make an alteration before it is again in action, but I assure you it is not altogether extinguished. I had been persuaded, in order to add to the force of the process, to put retorts and superheaters; these succumbed to the force of the flames and dropped. I have to take them out and put in my own simple apparatus, that exposes no iron to the fire. The expense of doing this is the only cause that prevents the boiler being in full action. I unhesitatingly pronounce that any method for burning liquid fuel that exposes iron to the flames, is wholly useless for any practical purpose. In your description of Mr. Crow's apparatus, you mention that he had conducted an experiment with creosote that produced 18·91lb. of water evaporation per 1lb. of creosote. This is quite true, but it was with my apparatus, not his. I gave him the use of my boiler at Woolwich for an entire day; creosote was burnt under his superintendence, and the result, as returned by the engineer of the yard, was as stated, one that could never be obtained by any apparatus exposed in the midst of the flames.—I am, Sir, yours, &c., C. J. RICHARDSON.

34, Kensington-square, W.

Meetings for the Week.

MON.—Society of Arts.—Dr. Lotheby on "Comparative Digestibility of Foods; Functions of Different Foods; Construction of Dietaries," at 8 p.m.

Royal Geographical Society.—E. D. Young, Esq., an "Account of the Livingstone Search Expedition," at 8.30 p.m.

TUES.—The Institution of Civil Engineers.—Colonel O'Connell on "The Relation of the Fresh Water Floods of Rivers to the Areas and Physical Features of their Basins," at 8 p.m.

WED.—Society of Arts.—Dr. Mann on "The Climate and Industrial Prospects of the Colony of Natal," at 8 p.m.

THURS.—Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

FRI.—Royal Institution.—Rev. F. W. Farrar on "Public School Education," at 8 p.m.

Royal United Service Institution.—Major General Michael W. Smith, C.B., on "Cavalry: How far its Employment is Affected by Recent Improvements in Arms of Precision," at 3 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Snilles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Naval, Military, and Gunnery Items.

THE operation of the Contagious Diseases Act, 1866, will shortly be extended by the Government to the garrison districts of Shorncliff, Colchester, and Cork, as well as the Curragh.

AT Orenburg, on the borders of Turkistan, a military school has been established for 200 pupils, 120 of whom are to be selected from the sons of Tartar and Kirghis chiefs.

CAPTAIN Le Messurier, with some well-borers and a staff, has arrived at the Abyssinian camp, and his first experiment, made on the 11th, about a mile from the shore, was highly satisfactory. The want of water is the greatest drawback to the efficiency of the Commissariat and Transport Train departments.

MESSRS. W. Denny and Brothers, of Dumbarton, are building two composite gunboats, each of 300 tons; an iron screw of 1,760 tons, named the "Saturno"; another iron screw of 3,000 tons, not yet named; another iron screw of 1,760 tons, not yet named; an armour-clad twin screw of 1,200 tons, and two iron screws of 1,100 tons each.

AT Chelsea Hospital Capt. Robert Grier, aged 75 years, died on Sunday. He entered the army in February, 1810, as Ensign in the 44th Regiment, and shortly afterwards went on service to the Peninsula. At the battle of Fuentes d'Onor he was wounded in the right shoulder; at the siege of Badajoz he led the advance of the feigned attack which ultimately became the successful one, and commanded the "forlorn hope" when the place was carried. He was in the campaign of 1815 severely wounded in the ankle at Quatre Bras. Capt. Grier had the war medal with three clasps, and the Waterloo medal. He was placed on half-pay in March, 1817, as Lieutenant, and was appointed a Captain of Invalids in September last.

HER Majesty's steam sloop "Shearwater," from the South Pacific, brought home a couple of men picked up in the Straits of Magellan on October 11 last, and who had subsisted during the preceding six weeks on mussels and other precarious food which they were able to gather from the rocks. The men when discovered were scarcely recognizable as Europeans, having been so thoroughly metamorphosed by their mode of existence and exposure to the severity of the weather, as to be taken for the native aborigines, if any were in existence. They both belong to H. M. sloop "Chanticleer," cast away in the ship's dingy in a gale of wind while in attendance on a shooting party of the officers of that ship, and reported to the Admiralty as dead. They were discovered by a similar party of excursionists from the "Shearwater."

THE "Kronstadt Wiestnik" observes that warlike preparations in France have latterly extended to the naval forces. The most marked activity is observable in the Government ship-yards. At this moment no less than 39 ships of different sizes are building for the Admiralty. Four of these are rams, on the "mixed principle," being half of wood and half of iron. One ram, "The Ocean," is to carry eight guns of the heaviest calibre in battery, and four others in towers. On the same system four corvettes are also being constructed to carry two guns on each side, and four others in as many immovable towers. These vessels will be comparatively small, and provided with powerful machines so as to attain great speed in the water. The French men-of-war steamers number 348; add to these 116 sailing vessels and the 39 in course of construction and we have a total of 503.

LATEST accounts from the Clyde show activity in the shipbuilders' yards. Thus we learn that Messrs. C. Conwell and Company, of Overnewton, have launched a composite screw of 800 tons, built for the China trade. Engines are being supplied to this steamer, which has been named the "Columbine," by Messrs. J. Howden and Company, of Scotland-street Engine Works, Glasgow. Messrs. W. Denny and Brothers have launched an iron screw named the "Saturno," built for the Austrian Lloyd's Steam Navigation Company. The dimensions of the "Saturno" (which is the seventh vessel of a similar class supplied by the same firm to the Austrian Lloyd's) are:—Length, 275ft.; beam, 34ft.; depth, 26ft.; burden, 1,760 tons new measurement. The builders will supply engines of 250-horse power on the direct acting service condensation principle. Messrs. Blackwood and Gordon, of Port Glasgow, have launched a screw steamer named the "Dungevan Castle." Her dimensions are 142ft. by 21ft., and 11ft. 6in. Her engines, which are of 70-horse power, are also made by Messrs. Blackwood and Gordon.

Miscellanea.

THE statue of the late Sir Robert Peel is placed in New Palace-yard, Westminster, but it is not yet decided when it is to be uncovered.

IN the six years 1861-66 the railway companies of the United Kingdom paid no less than £1,378,167 for legal and Parliamentary expenses.

THE "Serapis," just arrived from India, has brought a magnificent young tiger, in charge of Captain Wake, for the Zoological Society's Gardens.

THE "New York Herald," stating that at a recent funeral after a railroad accident, the hymn, "I would not live away," was sung, suggests that it be printed on the back of passengers' tickets.

THE American Patent-office reports that the whole number of patents issued during the year 1867 was 15,016, being an increase of 3,515 over the number of patents issued in 1866.

AN American paper states that in Windham County, Connecticut, the keeper of the gaol goes from house to house with a gang of prisoners (the refractory trammelled with a ball and chain), and jobs of wood-sawing for the people are attended to.

WE learn with much satisfaction that Joseph Whitworth, Esq., LL.D., F.R.S., &c., has consented to preside at the forthcoming anniversary festival of the London Association of Foremen Engineers, to take place on February 15, at the City Terminus Hotel, Cannon-street.

AN interesting memoir of Dr. Gale, of non-explosive gunpowder notoriety, from the pen of Mr. John Plummer, is in the press. The history of Dr. Gale, who is totally blind, forms a remarkable and encouraging chapter in the annals of self-help, and can hardly fail to gain considerable popularity.

THE trowel prepared for presentation to his Royal Highness the Duke of Edinburgh on the occasion of laying the foundation stone of a new town-hall at Melbourne, is made entirely of gold, both blade and handle. Where the two join, the trowel is ornamented with pearls and turquoises; at the other end, the handle has on it a duke's coronet, set off with diamonds and emeralds.

IN consequence of the death of Mr. Godson, Mr. W. M. Williams is appointed chief superintendent of the South-Western Railway. Mr. Verrinder, superintendent at the Waterloo terminus, and Mr. Tyler, of Exeter, are appointed assistant-superintendents, in conjunction with Mr. Williams. Mr. G. W. Hill, district superintendent at Windsor, succeeds Mr. Verrinder as superintendent at Waterloo.

LAST week the highway in front of the Red Lion Hotel, Dunstable, gave way suddenly, making a large hole some 6ft. deep and 10ft. or 12ft. in circumference, as though a well was being sunk. Old men say that a "middle row" stood on that spot years ago, and that dumb wells stood about in a line with the present centre of the highway. That is supposed to be the reason of this extraordinary subsidence.

A COMMITTEE of the Liverpool Chamber of Commerce has reported to the meeting of the council that they had made inquiries into rumours, which had caused much anxiety, that considerable quantities of gunpowder were stored in Liverpool, and they had ascertained that there was no cause for alarm, and that the arrangements for storing and delivering gunpowder were sufficient to prevent accident.

THE "Ackbar" of Algiers says, that in consequence of the abundant rain which has lately fallen in Algeria, vegetation around the capital has made immense progress. Buds and flowers are bursting forth with incredible rapidity. At Mustapha-Superior the greater part of the fruit trees are in blossom, and on others the fruit itself is beginning to be formed, and they have eaten plums of a second growth perfectly ripe; and this in the month of January!

THE visitors to the South Kensington Museum during the week ending January 18, were on Monday, Tuesday, and Saturday, free from 10 a.m. to 10 p.m., 6,825; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,689—total, 8,514. Average of corresponding week in former years, 9,568. Total from the opening of the Museum, 7,152,324. Patent-office Museum.—Number of visitors for the week ending January 18, 3,012; total number since the opening of the Museum free daily (May 12, 1858), 1,232,208.

WE regret to announce the death of Mr. Frederick Slight, for many years the secretary of the London and Brighton Railway. He was appointed to that

Digitized by Google

office abont 20 years ago, and continued to act as secretary down to the time of the important inquiries of the investigation committee last year. The anxieties connected with the financial embarrassments of the concern, are believed to have resulted in a premature decay of his powers. Mr. Slight was only 43 years old at the time of his death.

IN order to try the results of the French International Monetary Commission, which sat at the Ministry of Foreign Affairs, for the purpose of ascertaining if a uniform coinage could be adopted by all the civilized nations of the earth, a gold piece has just been struck as a common standard of money in France, England, and the United States. On the obverse is the effigy of the Emperor Napoleon, crowned with laurels, without any inscription; and on the reverse the following:—"5 dollars—25 Francs," and beneath—"Or: essai monetaire." This piece is also of the value of an English sovereign.

AN interesting discovery of ancient silver coins and ingots of the Gaulish period has been made at Goutrem (Eure). They are believed to belong to period of the Volsci-Tolosati, inhabitants of ancient Toulouse. The coins seem to have been cut off the ingots, and, without regard to the form of the piece, stamped as money, attention being paid only to their weight. A considerable number of them, and some of the silver bars, have been secured for the Museum of Rouen, already remarkable for its collection of ancient coins, and illustrations of early Gallic metallurgy.

A CORRESPONDENT writes:—The engine-drivers on the Enfield branch of the Eastern Counties Railway received from the passengers a few days since a testimonial of ten guineas, as an expression of their goodwill towards them, and satisfaction with their services. The amount was collected in half-crowns, and the men were much pleased to receive so kindly a token from their passengers. At this time of the year every one seems to be remembered, except the most important on the railway—viz., the drivers, and my reason for asking your insertion of this note is that others may think of their humble friends, and go and do likewise.

IN reporting on the preventable diseases of the industrial classes, the "British Medical Journal" calls attention to the condition of certain workers among metallic and mineral dust. The amount of consumption and other lung diseases caused by the inhalation of irritating particles, is excessive among engineers, machinists, and stonecutters. Of the men belonging to the Amalgamated Society of Engineers the larger proportion of deaths are due to different varieties of preventable lung diseases. An ample field is open to persons of some mechanical ingenuity and philanthropy in perfecting the necessary contrivances for protecting the air passages from the particles which, by their irritating action, give rise to these diseases.

AT the ordinary general meeting of the Institution of Civil Engineers, on Tuesday, the 14th inst., Mr. C. H. Gregory, President, in the chair, the following candidates were balloted for and duly elected: as Member, David Phillips; and as associates, T. P. S. Crosthwait, W. C. Faber, G. Farren, Major Furlong, R.E., T. E. Owen, Middleton Rayne, H. Y. Richardson, Jagannath Sadasewjee, James Stewart, Captain Hector Tulloch, R.E., and C. Wawn. It was also announced that the Council had admitted as Students of the Institution, Henry Adams, C. A.. Alberga, W. P. Birch, J. M. Campion, Lindsay Heath, A. W. Hemans, O. H. Howarth, W. H. King, F. H. Landon, A. H. Le Breton, F. H. Mollett, G. P. Pocock, G. H. Roberts, E. L. Robertson, D. S. Shaw, J. H. Waller, and Francis Wilton.

AT the ordinary meeting of the Royal Microscopical Society held at King's College, December 8—James Glaisher, Esq., F.R.S., president, in the chair—two gentlemen were elected fellows of the society. The president announced that a very valuable present had been received from Dr. G. C. Wallich, consisting of his entire collection of slides, numbering in all 1,031, a book containing his original drawings of microscopic objects, and a quantity of unmounted material. A paper was read by Professor Rupert Jones, F.G.S., on Fossil Bivalve Entomostraca, which were shown to be abundant throughout the whole geological series, but especially entering into the composition of various kinds of limestone. Charles Stewart, Esq., and Charles Tylor, Esq., were appointed auditors, and the annual meeting of the society was announced to take place on February 11.

IN accordance with instructions received from the Secretary of State for War, some important trials in connection with the consumption of gas, and which promise to be of great advantage to the public, were completed at the gas works of the Royal Arsenal, Woolwich, on Tuesday last. It has been found that by combining bitumen with coal in gas retorts that the gas is evolved with great rapidity, and that it gives an illuminating power from one burner equal to twenty-five spermaceti candles. The experiments, which have been conducted by Captain the Hon. Arthur Cocklin, C.B., of the Steam Reserve, Sheerness, have been so satisfactory that 200 tons of bitumen have been ordered by the War Department for use in the Arsenal.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order oj the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1678, 1706, 1735, 1742, 1749
BUILDINGS AND BUILDING MATERIALS—1732
CHEMISTRY AND PHOTOGRAPHY—1808
CULTIVATION OF THE SOIL, including agricultural implements and machines—1709
ELECTRICAL APPARATUS—1720, 1750, 1755, 1770, 1771, 1772
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1666, 1675, 1683, 1685, 1688, 1695, 1700, 1712, 1719, 1725, 1726, 1733, 1734, 1743, 1744, 1752, 1758, 1774, 1795, 1807
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1698, 1729, 1751
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1792, 1796, 1805
GENERAL MACHINERY—1665, 1671, 1677, 1680, 1684, 1690, 1691, 1692, 1693, 1696, 1702, 1704, 1705, 1707, 1716, 1728, 1753, 1756, 1760, 1761, 1768, 1769, 1777, 1779, 1781, 1783, 1799, 1801, 1802, 1809
LIGHTING, HEATING, AND VENTILATING—1668, 1673, 1748
METALS, including apparatus for their manufacture—1701, 1714, 1739, 1747, 1767, 1784, 1803
MISCELLANEOUS—1663, 1667, 1669, 1674, 1676, 1679, 1686, 1689, 1694, 1703, 1708, 1710, 1711, 1713, 1715, 1718, 1722, 1730, 1731, 1738, 1745, 1746, 1754, 1759, 1763, 1765, 1766, 1775, 1776, 1780, 1782, 1786, 1788, 1789, 1790, 1797, 1800, 1804
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1672, 1681, 1682, 1699, 1721, 1723, 1724, 1727, 1736, 1737, 1740, 1762, 1773, 1793, 1798
SHIPS AND BOATS, including their fittings—1697, 1778
STEAM ENGINES—1661, 1787, 1791
WARFARE—1664, 1670, 1687, 1757, 1785, 1806

1630 A. ALBRIGHT. *Covering buckles, saddle-trees, turrets, hooks, and other metallic trimmings for carriages and harness with a coating of vulcanized or hard rubber, gutta-percha, or prepared gum.* Dated June 1, 1867.

The buckle, or other article to be covered, is first enveloped with a coating of rubber or rubber paste, and is then enclosed in a suitable two part flask; the said flask is then put into a boiler or "vulcanator," and "vulcanized" to the desired degree of hardness, in the manner in which vulcanizing is usually practised. When gutta-percha, or other material, is used instead of the rubber, the mode of application is somewhat similar.—Patent abandoned.

1631 E. TAYLER. *The facilitating the composition or arranging of type of various founts, for displaying jobs or other works usually required to be done in printing offices.* Dated June 1, 1867.

This invention consists of a double sack or frame in which the cases or trays for holding the type are placed on a small frame revolving on pin joints or axles passing into or through two or more wheels resting on an axis, and one or more disc or discs, and the angle of the said cases or trays are alterable at pleasure by the movement to or fro of the position of one or more wheels, whereby the elevation or depression of the said disc or discs is effected, thereby raising or depressing the further or upper side of the small frame holding the said cases or trays.—Patent abandoned.

1632 T. HORREX. *Improvements in machines for hatching eggs.* Dated June 3, 1867.

The patentee adopts a flat case of metal or other material (to hold water or other fluid mixed) in or upon a box, frame, or stand, in an inclined position, and at one end of the box or frame, and under the lower end of the flat case holding the water, which is rounded for the purpose, he places a small lamp or gas burner; but he prefers a small tray of tin or other metal partly filled with oil, upon which is floated a wick, and placed under the lower or rounded end of the flat case holding the water, so as to heat the water or fluid therein. Under the other or higher end of the flat case holding the water he places a box or tray of a wedge-like form for the eggs to be placed in. By the box or tray being of this shape or form, the eggs can be placed close to, or at a distance from, the under surface of the flat case holding the water or fluid, by slightly pushing the box or tray forward, or withdrawing it in a wedge-like manner, by which means the heat of the eggs can be regulated. Around the top of the box or tray he fastens tubing, or list, or other material, to prevent the heat escaping, and he partly fills the box or tray with sand, or other material, to assimilate it to the ordinary hen's nest.—Patent completed.

1633 W. PIDDING. *Improvements in reels or receivers upon which threads, silks, or other fibrous material, in connection with needles (threaded or otherwise) are arranged, as also in the arrangement of needles threaded with any fibrous material, for the purpose of facilitating the use or uses of the same for all purposes of needlework.* Dated June 3, 1867.

Provisional protection has not been granted for this invention.

1634 E. MCLEAN. *Improvements in the construction of pianofortes and harmoniums.* Dated June 3, 1867.

This invention consists in making the top or lid of the case of such instruments of an arched form, in contradistinction to the forms hitherto employed, thereby leaving a cavity for the sound over the wrest plank. The top may be arched in the direction of its length or of its breadth, or the said arch may be a semicircular, elliptical, undulating, or other suitable form, but when of an undulating form, it is, according to this invention, made with a surface on the underside of a comparatively uninterrupted hollow curved form, the curve being only slightly returned at the sides or ends, or both; openings or holes of an ornamental, or other form, may be made in the ends or sides, or both, of this arched top, for the emission of the sound, and the exterior may be ornamented in a variety of ways.—Patent completed.

1635 W. H. RICHARDSON. *Certain improvements in the manufacture of iron and steel, and in the means or apparatus for effecting the same.* Dated June 3, 1867.

This invention has for its object the purification of iron when in the liquid state for the purpose of obtaining an improved metal from which castings may be produced, from which steel may be manufactured, and also for the purpose of cheapening the cost of, as well as the time occupied in, producing such metals or materials, and consists as follows:—After the ore is reduced in the blast furnace to the state of molten crude metal, the furnace is tapped, and the liquid metal run off into a vessel or receptacle where a blast of atmospheric air—which may be of a pressure of 4lbs. on the square inch, and upwards—is introduced into its mass through a hollow or tubular rabble or stirring rod of dimensions suitable to the mass of metal under treatment, similar to that shown and described in the drawings and specifications of letters patent granted to the present patentee the 4th December, 1866 (No. 3189), and which may be operated by hand or otherwise.—Patent completed.

1636 J. F. BROWN. *Improvements in looms for weaving.* Dated June 3, 1867.

The essential feature of this invention consists in the application to power looms of a certain apparatus, by means of which an instantaneous stoppage of the loom may be effected. In carrying this invention into practice the ordinary fast and dead pulleys are dispensed with, and in their place a frictional clutch is substituted, one-half of which is fixed on the driving shaft in the same manner as the ordinary fast pulley. The periphery of the clutch, or of one clutch plate, is formed so as to receive the driving belt, and thus constitutes or fulfils the office of a driving pulley. A clutch handle is provided for the purpose of pressing against or withdrawing the clutch on one clutch plate from the clutch box or other clutch plate, so that, by pressing the fixed half of the clutch against the revolving half, the frictional contact thereby produced instantly stops the loom, so that the gearing or mechanism for actuating the cloth beam is prevented from winding up the cloth.—Patent abandoned.

1637 C. L. J. CARVILLE. *Improvements in the construction of boilers.* Dated June 3, 1867.

These improvements comprise—First, the formation of capacities or spaces of strong corrugated sheet metal, so as to form vessels or boilers affording a free circulation for water and the generation of steam, as described. Second, the joining or uniting of the said corrugations at certain distances. Third, the employment in steam boilers of vessels or capacities made solely according to this invention, or in combination with steam generators of ordinary construction. Fourth, an arrangement for supplying heated water to steam boilers. Fifth, the production of superheated steam. Sixth, the employment of valves whereby the direction in which the heat circulates may be regulated as required or desired. The different parts of boilers made according to this invention are formed of two sheets of metal, or of a single corrugated sheet, and united in such manner that the two cavities or hollows are opposite one another, and thus form a capacity or boiler; and in order to maintain these parts at a desired distance apart, there are two projections or flanges opposite one another which are united by girders, bolts or screws.—Patent completed.

1638 D. BARKER. *Improvements in the construction of chambers for drying artificial fuel and other substances.* Dated June 3, 1867.

According to this invention the outer walls of the chambers are built of brick, or of other material or materials adapted for the purpose, angle iron plates being introduced into or attached to the walls, the same forming rails for the support of the movable trays hereinafter mentioned; and also for the support of bars to which are suspended the steam or hot air pipes when the same are employed for the purpose of heating the chamber. The blocks of fuel are placed upon iron trays furnished with wheels, the trays being connected with each other by dove-tailing or otherwise. The trays are introduced into and removed from the chamber by means of an endless band, or other analogous or suitable arrangement.—Patent abandoned.

1639 S. HARWOOD. *Improvements in the construction of walls, buildings, and other similar structures.* Dated June 3, 1867.

This invention relates to certain improvements in the construction of walls, buildings, and other such structures composed of layers of blocks or slabs of material in the nature of cement compositions, whereby complete ventilation is effected, and great strength afforded to the structure with a less weight and quantity of material than has hitherto been the case. The inventor proposes to form the blocks or slabs by means of moulds, the materials consisting of concrete, pure Portland cement, Roman cement, or any other cement or lime, or lime and cement, or other known compounds suitable for the manufacture of hard and durable blocks of artificial stone, and to build the wall or other structure of a hollow or cellular form by placing or laying the blocks or slabs in courses side by side with a space or interval between the rows, which may be two, three, or other number, and by binding the courses with similar blocks or slabs, either touching each other or with a space between each—Patent abandoned.

1640 R. W. PAGE. *Improvements in the construction of hand garden engines and hydropults.* Dated June 3, 1867.

This invention relates to a novel construction of garden engine for pumping and forcing water for use by hand, the engine being also useful as a hydropult for extinguishing fire, and for other purposes. It consists of a cylinder of brass, or other suitable metal, provided at one end with a stuffing box through which a piston rod or plunger is made to work, actuated by the right hand of the operator; the other end of the cylinder is fitted to an air-tight globe or vessel, to the opposite side of which an outlet pipe is fixed by a screw or otherwise, in order to cause the water to flow as a jet or stream. The piston rod has an inverted cone of metal fixed thereon near the globe, and the extremity of the rod is provided with a fixed metallic perforated disc or plate fitting the bore of the cylinder. Between the cone and disc the cap leather is placed on the rod loosely; it fits the cylinder, but its base is perforated

Digitized by Google

with an orifice larger than the diameter of the piston rod, to which a suitable handle is attached. At the side of the cylinder, and close to the handle, a short metal branch or nozzle is fixed, containing a conical inlet valve set in a corresponding seat; the base of this conical inlet valve is provided with a dome or semicircular plate of metal placed at right angles or vertically on or across the centre of the base of the conical valve, which fits or partly fits into a hemispherical recess in the branch when the valve rises from its seat. The narrow end of the valve is furnished with a triangular guide or sliding rod working in the circular bore of the branch for the sake of steadiness, and an india-rubber or other tube of suitable length is joined to the branch, and the other end is furnished with an inverted cup covered with wire gauze, which cup is to be inverted in a cistern or other vessel if the engine is to be used in a greenhouse or hothouse, or in a vessel of water if to be used in a garden or other situation, the gauze preventing the entrance of any foreign substances which might interfere with the action of the valves or piston. The air globe or vessel is provided interiorly with a short flexible tube communicating with the outlet pipe or rose; this tube is weighted at the end so as always to fall to the bottom of the reservoir or globe, in order that it shall always be beneath the level of the water. The action of the engine will be obvious from the above description.—Patent abandoned.

1641 J. INSHAW. *Improvements in electrical clocks, which improvements may also be applied to other electrical instruments.* Dated June 4, 1867.

This invention consists of the improvements hereinafter described in the commutators or contact breakers of electrical clocks and other electrical instruments, by which improvements great simplicity in the construction of the said commutators or contact breakers is effected, and great certainty in their action secured. The patentee describes the invention in connection with a commutator or contact breaker of an electrical clock. On the rod of the electrical pendulum of the clock are two tappets, between which a vertical wire is situated, the said wire being connected with a horizontal slide, so that by the motion of the pendulum the said tappets, acting on the said vertical wire near each end of the stroke of the said pendulum, communicates an intermittent reciprocating motion to the said slide, and effect the interruption and completion of the electrical circuit, as hereinafter explained. The said horizontal slide has near one end of it a raised portion which, in the traversing motion of the said slide produced by the pendulum, is brought under and into contact with the lower end of a vertical wire connected with one of the plates or elements from which electricity is derived. The said slide works in two supports. One of the said supports in which the slide works is connected with the other of the plates or elements from which the electricity is derived, and between the said support and the vertical wire, and connected therewith, are the coils which actuate the pendulum of the clock, as well as the coils of any other clocks the motion of which is regulated by the pendulum of the first-named or primary clock.—Patent completed.

1642 M. CAVANAGH. *Improvements in adjustable lock spindles.* Dated June 4, 1867.

This invention has for its object improvements in lock spindles with a view of rendering the several parts thereof more complete and suitable for being applied and accurately adjusted to any thickness of door, and consist in employing with the ordinary tapped square spindle a regulating swivel screw nut, and sliding boss or nozzle, in combination with fixing studs and coupling socket turning upon the mount of the movable knob or handle, by the arrangement of which, on the said spindle being adjusted to the required thickness of door, through the medium of the swivel nut, the said studs on the boss are caused to take into a notched concentric inner groove in the said coupling socket, whereby the knob or handle is firmly held or retained upon the spindle, in like manner to the bayonet fastening.—Patent completed.

1643 J. WADDINGTON and B. LONGBOTTOM. *Certain improvements in moulds to be employed in casting Bessemer steel and other metals.* Dated June 4, 1867.

This invention is designed to render the moulds employed in casting Bessemer steel or other metals more durable by so forming them that the lower portion which first becomes deteriorated may be removed and a new portion substituted. Hitherto such moulds have either been made of one solid piece, or divided vertically in halves, the better to release the ingot. The improvements consist in dividing the moulds horizontally, that is, so as to make a top and bottom portion; the edges of these parts which meet together are grooved or so formed as to fit into each other, and the upper and lower parts are secured together by bolts passing through lugs outside the mould. When preparing a mould for use, a cement is filled in between the joint, and a temporary plug is passed inside the mould to prevent the cement squeezing into the mould; the bolts are then drawn up tight, and the spare cement squeezes out on the outside of the mould. Thus, when the interior surface of the lower portion becomes worn or eaten away by the splashing of the metal, it can be replaced by another one, the upper part serving many lower ones.—Patent completed.

1644 G. DAVIES. *Improvements in the construction of paddlewheels.* (A communication.) Dated June 4, 1867.

This invention consists in the combination of a series of main floats, and a series of auxiliary floats, in connection with two wheels, the whole being constructed and arranged substantially as hereinafter described. Between these two wheels, and attached to them at their rims and spokes, is a series of floats composed of metal or wood; these floats form an obtuse angle with each other at their centres, and are attached at their outer ends on each side to the wheels, being arranged at equal distances apart. In revolving the paddle-wheel for the purpose of propelling a vessel, the said wheel is to turn in such a direction that the outer ends of the floats shall first enter the water, and the force of the latter shall be exerted against the inner or concave side of the bucket. Extending from the spokes of the side wheels are two auxiliary wings or floats attached at their inner ends to the main floats, and set at a reverse angle to the same for the purpose of enabling the wheel when its motion is reversed to propel the vessel astern, these auxiliary floats also serving as braces or supports for the main floats—Patent completed.

1645 T. LAIDLAW. *Improvements in the manufacture of yarns used for weaving textile fabrics, and in the machinery employed therefor.* Dated June 4, 1867.

This invention has for its object the production of yarns on which a spot is formed at intervals by the more close overwinding of one yarn upon the other, the intervening spaces being twisted in the usual spiral manner, and is carried out as follows:—A wheel is fixed on the driving shaft of the twisting frame, and it actuates another wheel on which a wiper or cam is fixed, which wheel, during one part of its rotation, comes in contact with the end of a rod or bar; it forces the rod forwards, causing it to operate upon a lever that actuates the feeding gear, so that during the time the wiper or cam acts upon the rod, a spiral twist is produced, and when the lever is drawn back by means of a spiral spring, a spot is produced.—Patent completed.

1646 E. MELDRUM. *Improvements in the purification of paraffine.* Dated June 4, 1867.

This invention consists in purifying paraffin oil by treating it, whilst in a cold unmelted state, with naphtha.—Patent completed.

1647 J. H. JOHNSON. *Improvements in racks or holders for whips, canes, and other like articles.* (A communication.) Dated June 4, 1867.

This invention relates to racks for holding whips and other articles, and consists in the combination with a skeleton or perforated frame of wood, or other suitable material, of an elastic binding or holding device arranged in the perforations of the said frame in such manner as to hold any object placed or inserted in the perforated frame. The rack thus constructed can be put to various uses.—Patent abandoned.

1648 J. M'OWEN. *Improvements in fire-grates.* Dated June 4, 1867.

In house fire-grates of the usual construction there is a grate on which the fire rests, and through which the ashes drop. Now, the nature of this invention consists in the application and use of two grates, the top one of which is a fire-grate for the fire to rest upon, and the bottom one is a coarse grate, and between or under the grates the patentee places a sliding valve which can be opened or closed at pleasure. By these means more or less air can be supplied to the fire by opening or closing this valve.—Patent completed.

1649 H. W. HART. *An improved construction of raft.* (A communication.) Dated June 4, 1867.

This invention relates to a novel construction of portable raft which combines lightness and buoyancy with an extended supporting surface. The raft may be described as a disc of canvas forming the floor attached to and extended over a number of conical shaped air-tight floats, set radially around a vertical hollow cylinder, and connected thereto by links. The interior of this cylinder is divided up in any convenient manner to enable it to receive and secure from injury fresh water and provisions.—Patent abandoned.

1650 D. HANSON. *Certain improvements in furnaces, and in apparatus to be employed in the construction of steam boilers.* Dated June 5, 1867.

According to one part of this invention, the patentee uses a furnace so constructed that, by introducing the end of a tube or ring into it, a certain width of it is heated all round the circumference, instead of only part. For this purpose he arranges the furnace in such a manner that the flame and heated gases on their way from the fire-place to the chimney surround and envelope the whole circumference of the tube as far as it projects into the furnace, and thus heats it. The combustion of the fuel in the fire-place may be promoted by using the blast from a fan blower or by causing a draught by a steam jet, or by other well known means usually adapted for this purpose. In front of the furnace the tube is supported on rollers to which a revolving motion is imparted by suitable gearing, and which again transmit motion to the tube that rests on them; by this means every part of the circumference of the tube in rotation is exposed to the greatest heat over the fire-place, and thus the whole circumference is heated gradually and equally all round. When the tube is heated it is taken out of the furnace and is fixed to the face plate of a flanging machine (which forms another part of this invention) with the heated edge outwards. This face plate is carried by a shaft which may be inclined to a required angle, and this shaft is also provided with suitable bearings in which it is caused to revolve, the revolving motion being imparted to it by gearing. The heated edge of the tube or ring is then taken between an upper and lower roller die, so shaped that, when pressed together, they bend or turn down the edge of the tube and form a flange all round the circumference as the tube revolves. These roller dies are so arranged that they can be adjusted to the length of the tube, and that they can be pressed together by steam or hydraulic pressure, by racks and pinions, or other well known means. A further part of this invention consists in an improved machine for bending metal plates. The patentee employs three pairs of horizontal rollers, which are so arranged that only the lower roller of the middle pair remains in a fixed position, while the top roller can be raised or lowered, and that the two outer pairs of rollers can be raised or lowered either singly or together, and also that the axes of the outer rollers can be made to stand at an angle relative to the axis of the centre pair; and, further, that the top rollers can each or all be removed. Three or more rollers can be arranged to work together at one time. According to the relative position of the rollers to one another, when a plate is passed between them, it is either straightened or curved. On one side the gearing is arranged for driving the rolls. Lastly, the invention consists in accomplishing horizontal and vertical riveting by one machine, instead of having a separate machine for each of these operations, as heretofore. To give the necessary motion to the riveting machine he uses such suitable gearing cams and levers as are usually adapted for this purpose, but he so combines and arranges these levers that they may be worked for both or either operations from the one cam shaft, or other suitable transmitter of power.—Patent completed.

1651 J. GAUDET. *Improvements in night and fog signal apparatus for preventing accidents on railways.* Dated June 5, 1867.

The object of this invention is so to arrange apparatus that the signalman (in case of fog or derangement of the ordinary signal apparatus or other cause) may set up one or more lever arms or projections at suitable distances upon the line or permanent way of railway, such lever arms or projections being placed in a position to act upon a lever or other instrument, carried by the locomotive or guard's van, in order to communicate a signal by means of a bell or otherwise to the driver or guard, for the purpose of inducing caution or to stop the train.—Patent abandoned.

1652 N. RAUSCH and E. L. DARLET. *Improvements in the manufacture of artificial fuel.* Dated June 5, 1867.

This fuel is composed by mixing any kind of ordinary coal with argillaceous or any other earth or earths possessing similar or analogous properties, or, by preference, with peat earth together with chloride of sodium and mucilage, the latter being formed by boiling flax or linseed, or, by preference, Carragheen moss, or other moss or lichen possessing analogous properties, in water to the consistence of a thin syrup. The proportions in which these several substances are combined together may be varied according to the nature of the coal under treatment, and the degree of cohesion which it is desired the fuel shall possess.—Patent completed.

1653 T. H. SAUNDERS. *A new hygienic oil or gas stove.* Dated June 5, 1867.

This invention is not described apart from the drawings.—Patent completed.

1654 C. BOULAY. *Improvements in galvanic batteries.* Dated June 5, 1867.

The patentee claims the construction of galvanic batteries or elements in which each of the electric motive metals or bodies is situated in direct contact with a suitable exciting material or materials, or mixtures of them, in the dry or slightly moistened state, the moisture being transmitted by little and little to the said exciting materials from a suitable solution, or from partly dissolved crystals from which the exciting materials are separated by a porous partition plate or diaphragm, the entire element being covered by a layer of any suitable cement, as described.—Patent completed.

1655 G. WHITE. *Improvements in the manufacture of hydrate and carbonates of soda.* (A communication.) Dated June 5, 1867.

These improvements relate, first, to the application in this manufacture of either the hydrated oxides of iron or zinc, or carbonates of these latter. Second, to certain modes of recovering hydrated oxides of iron or of zinc from the sulphur of iron or of zinc resulting from the said treatment. For manufacturing hydrate or soda or caustic soda, either hydrated oxide of iron or of zinc is added in atomic proportions, according to the laws of chemical equivalents, to an aqueous solution of sulphuret of sodium, whereas if carbonate or bicarbonate of soda is to be obtained, carbonate of iron or of zinc is added to the said solution. In both cases a precipitate of sulphuret of iron or of zinc is formed, and if the hydrated oxide has been made use of, a solution of hydrate of soda is obtained, whereas if the carbonate has been employed, a solution of carbonate or bicarbonate of soda is the result; from these solutions the caustic soda or the carbonate or bicarbonate of soda may be obtained. From the precipitated sulphuret of iron or of zinc hydrated oxide of the said metals subservient for another operation may be obtained.—Patent abandoned.

1656 L. B. SCHMOLLE. *Improvements in crinoline skirts.* Dated June 5, 1867.

This invention consists in constructing crinoline skirts to slope away in a curved line towards the bottom or both sides from a point in front below the waist, instead of making the skirt of the same length all round.—Patent abandoned.

1657 I. EVANS. *Improvements in spring hooks.* (Partly a communication.) Dated June 5, 1867.

This invention consists in making double hooks, or hooks having double heads and beaks, the one passing the other, and the beaks in opposite directions, so that the head of the hook is in two thicknesses, thus forming a spring hook which may have a swivel or loop attached to it according to the use for which it may be intended.—Patent completed.

1658 I. M. MILBANK. *An improvement in breech-loading firearms and cartridges adapted to such arms.* Dated June 5, 1867.

This invention is not described apart from the drawings.—Patent completed.

1659 J. ADAMS. *Improvements in machines for dating or printing of railway and other tickets.* Dated June 6, 1867.

This invention is carried out as follows:—Upon a small iron frame the inventor fixes two upright standards, in one of which are drilled two holes, and in the other one hole; into two of these holes is fitted a horizontal shaft, having an arm or crank fixed on to one end, and a similar arm or crank is fitted in to the other hole, and upon these two arms or cranks is fitted another upright having a box or case for carrying the type for printing; at the bottom in front of the iron frame is fitted a recess or mouthpiece to receive the tickets to be dated, and working upon two uprights beneath the type box is placed horizontally a movable ink tray, so that when the ticket is pressed in to the mouthpiece, it moves forward, the ink tray then lowers itself, and the type comes down parallel upon the ticket, and dates it; the machine is then brought back to its former position by means of a steel spring fixed on to the horizontal shaft working in the upright standards.—Patent abandoned.

1660 B. TEMPLAR. *Improvements in fastenings for window sashes.* Dated June 6, 1867.

This invention consists in making the fastenings of window sashes self-acting, so that when the window is closed, the sashes are securely connected together, and cannot be opened from the outside. Another part of the invention, which is applicable to fastenings of the ordinary construction, as well as to these improved fastenings, consists in making the casement plate of the bracket of the bottom sash to overlap that of the other, to prevent the introduction of a knife blade or other instrument in order to throw back the catch.—Patent completed.

1661 E. BLAND. *Improvements in steam engines.* Dated June 6, 1867.

This invention consists in the use and application of the common girdiron valve in such a way that the steam and exhaust valves are placed in separate compartments, and as near to the inner side of the cylinder as the thickness of the metal of the cylinder side will allow. The admission valves are placed at or near the ends of the cylinder, and at any convenient part of the cylinder's circumference, and the exhaust valves are placed also at or near the cylinder ends, and in any other part of the cylinder's circumference that is not occupied by the inlet valves that may be convenient. The object of using the above-named valves, and placing them in the positions mentioned, is to prevent undue waste of steam by having as little space as possible between the valves and the interior of the cylinder.—Patent completed.

Digitized by Google

1662 J. LIVESEY. *Improvements in paper folding machines.* Dated June 6, 1867.

Provisional protection has not been granted for this invention.

1663 T. BROWN. *Improvements in artificial limbs.* (A communication.) Dated June 6, 1867.

The first part of these improvements relates to the knee joint of an artificial leg, and to the means of holding the said joint in any desired position, and consists, chiefly, in the employment of a T-shaped bracket or standard, which takes the place of the tibia, and the lower or T-shaped end of which is provided with journals which are fitted to work freely in oblique boxes secured in the interior of the knee pan. When the knee joint is bent, as in sitting, it is retained in position by the action of a pear-shaped button with a spherical head which works in a socket formed in the head of an oscillating vertical sliding rod or bolt. —Patent completed.

1664 T. WILSON. *Improvements in the construction of breech-loading firearms, and in the manufacture and construction of cartridges for breech-loading firearms.* Dated June 6, 1867.

This invention is not described apart from the drawings. —Patent completed.

1665 R. MAYNARD. *Improvements in chaff-cutting machinery.* Dated June 6, 1867.

According to this invention the patentee constructs chaff cutting machines with a multiplicity of knives. He fixes at least five knives on the arms of a vertical wheel, which is made to revolve against a mouth of a greater width than is at present used in machines for this purpose. Through this mouth the straw is expelled in the usual manner. The invention further includes a riddle combined with the chaff cutter, the said riddle being made of strips of thin metal bent to a zig-zag form, and soldered one to the other, so as to form a surface with holes of a hexagonal form. For facility of removal from place to place, he mounts the machine, fitted as described, on travelling wheels.—Patent completed.

1666 E. ELLIS. *Improvements in twist lace machinery.* Dated June 6, 1867.

The object of this invention is more effectually and conveniently than heretofore, to act upon the fabric in a twist lace machine after it has been produced and taken up by the ordinary points, so as to drag or bias the fabric correctly to the form or pattern required, such drag or bias of the fabric being either to the right or to the left, or upwards or downwards, as may be required.—Patent abandoned.

1667 G. R. TURNER and W. T. ALLEN. *Improvements in the manufacture or construction of gates and fences, part of which invention is applicable to straining wires and to other straining purposes.* Dated June 6, 1867.

This invention consists in combining with end uprights formed of T angle or tube iron, or other iron or metal, of sufficient strength to bear the resistance of the intermediate portion of the gate, and with one or more intermediate rails, likewise of the necessary strength, horizontal bands or strips of hoop iron, &c., strained or drawn to a tension and secured round the ends, or from end to end. The invention consists, second, in straining or producing a tension in the cords, so that the strain of one strand counteracts the strain of another strand or length, the strain being kept equally divided.—Patent abandoned.

1668 T. STURGEON. *An improvement in street and similar lamps.* Dated June 7, 1867.

This invention consists in using, instead of the four glass sides which form the upper part of street and similar lamps, pieces of tin or other substance possessing a bright reflecting surface, so that the light which at present passes through the glass in the upper part of the lamp will be reflected down again into the street, and thus increase the effective illuminating power of the lamp.—Patent abandoned.

1669 C. E. GIOJOLA, J. H. GRAY, and P. MARTINENGO. *Improvements in inkstands.* Dated June 7, 1867.

This invention relates more particularly to fountain inkstands, and has for its objects, first, to maintain a uniform level of ink or other writing fluid at any required height in the dipping cup; and, second, to provide a more facile means for filling, emptying, and cleansing the body or reservoir of the said inkstand. For effecting these objects the patentees carry a tube horizontally into the body or reservoir from the aperture through which the ink ordinarily flows into the dipping cup. This horizontal tube and dipping cup may form an integral part of the inkstand, or be fitted thereto. Immediately over the horizontal inner tube they form a vertical air duct or pneumatic tube. This air duct or pneumatic tube is open at the bottom end, and terminates a short distance above the top of the horizontal inner tube of the dipping cup: it is also provided with an aperture at or near the top through which the air passes down the tube to the surface of the fluid in the body of the inkstand.—Patent completed.

1670 A. ELVINS. *Improvements in breech-loading firearms.* Dated June 7, 1867.

This invention has reference to breech loading firearms with hinged barrels, and consists, first, in an improved arrangement for actuating "the extractor" on the falling forward of the barrel or barrels. For this purpose the inventor forms or fixes upon the breech-piece, below the barrels, and a short distance behind the axle pin, a projecting finger which passes up into a recess in the under side of the barrels. Another part of the invention has reference to an improved "snap action" for securing the barrel or barrels when closed up. For this purpose a recess or slot is formed in the part of the breech-piece below the barrels, and a cylindrical bolt passes through the side of the breech-piece across such slot, being provided outside the breech-piece with a lever, whereby it can be turned round to a certain extent.—Patent abandoned.

1671 A. L. BRICKNELL. *Improvements in rotary pumps.* Dated June 7, 1867.

This invention has for its object improvements in rotary pumps, and consists in giving a tapered sectional form to the annular space enclosed between the two flanges carried by the rotating cylindrical centre piece of such pumps. —Patent completed.

1672 J. OFFORD. *Improvements in means or apparatus for signalling between different parts of railway trains.* Dated June 7, 1867.

This invention relates to means whereby railway passengers may call the attention of the guard when his presence is required. The inventor employs a lamp, which, under ordinary circumstances, is below the roof of the carriage, but which is provided with suitable guides to enable it to be pushed up at pleasure and show light over top of carriage.—Patent abandoned.

1673 H. CROWE. *Improvements in hot water apparatus for heating purposes.* Dated June 7, 1867.

These improvements consist in concentrating the heated currents of water arising from the heating surfaces of the boiler, and directing them into a separate compartment at the upper part of the boiler, and in making the outlet for hot water from this compartment, and after circulating the hot water through the pipes returning it cooled to the bottom of the boiler to a cavity, vessel, or compartment under or around the boiler and ashpit.—Patent abandoned.

1674 E. S. ATKINSON. *Improvements in the manufacture or treatment of oakum or other fibrous substances for caulking ships and for other similar purposes.* Dated June 7, 1867.

The patentee claims the saturation of oakum and other substances with an infinite variety of the products of distillation of mineral and vegetable substances, not binding himself to any special quantities or mixtures.—Patent completed.

1675 D. ROBISON. *An improved arrangement of reeds to be used in looms for weaving.* Dated June 7, 1867.

This invention consists in so constructing the reeds used in looms for weaving that the warp threads shall not rub or wear against each other during the shedding of the warp, as is at present the case, and this object is carried into effect by using one or more reeds placed one behind the other, so that the split of one reed intersects or divides the split of another situated either before or behind it, and it is preferred to call this arrangement of the reeds "bosoming;" and the one or more reeds so used are combined together into one and the same rib or frame, and placed in the lag of the loom in the ordinary manner.—Patent abandoned.

1676 J. PETRZYWALSKI. *An improved camera obscura, to be called the Photomegascope.* Dated June 7, 1867.

This improved apparatus consists of a square or other shaped wooden or metal box formed of two parts, one sliding within the other, which facilitates the adjustment of the focus, and forms a dark chamber, at one end of which is a sheet of ground glass, whilst at the opposite extremity the object to be reflected is placed; at one, but preferably on each side of the object, a lamp is placed, a similar one being in front thereof; the rays of the three lights being concentrated by reflectors on the object, the said rays are reflected on the ground glass on an enlarged scale by powerful lenses mounted in the usual way for such purposes, and fixed in a sliding panel in front of the lamps and object.—Patent completed.

1677 E. T. HUGHES. *Improvements in sewing machines.* (A communication.) Dated June 7, 1867.

This invention is not described apart from the drawings. —Patent completed.

1678 W. W. and J. WOOD. *Improvements in the mode of fitting the tubes in the flues of Cornish and other steam boilers* Dated June 7, 1867.

According to this invention the patentees make the cross or diagonal tubes with a flange at each end in one and the same piece with the cross or diagonal tubes; or otherwise both the said flanges are to be attached to the flue or fire box of the boiler inside. They make the flanged ends of the said cross or diagonal tubes at an oblique angle to the centre line of the said cross or diagonal tubes, so that when the tubes are fixed in position in the flue of a steam boiler, the said cross or diagonal tubes will not be at right angles to the centre line of that flue.—Patent completed.

1679 J. SHELDON. *Improvements in brushes, and in apparatus for manufacturing the same.* (A communication.) Dated June 7, 1867.

This invention consists, chiefly, in securing each bunch or tuft of fibres by a separate wire staple, the points of which are bevilled or inclined on the outside in such a manner that, when driven into a hole or perforation in the stock, its points have a tendency to spread crosswise and take a firm hold of the same.—Patent abandoned.

1680 A. BARRY. *An improved mode of, and means for, communicating motion to cranes, and regulating and controlling the operation of the same.* Dated June 7, 1867.

The improvements consist in the employment of an adjustable guide roller or rollers in combination with a driving belt which communicates motion from the engine to the crane. The system is particularly applicable to cranes whose motive power is obtained from the explosion of gas, and whose work is light, and requires much nicety of regulation.—Patent completed.

1681 J. OFFORD. *Improvements in wheel carriages and other vehicles.* Dated June 7, 1867.

This invention relates, firstly, to improvements in wheels whereby they are rendered somewhat elastic, and yet sufficiently rigid to give the required strength. For this purpose, according to one arrangement, the inventor forms the axle box with one fixed and one loose flange, and between such flanges he fixes a metallic ring or tube, around which he places a ring or tube of vulcanized india-rubber, or other suitable elastic material. He also places a washer of vulcanized india-rubber, or other suitable elastic material, against each flange, and between such elastic washers—and around the elastic ring or tube are placed the ends of the spokes, which are tapered so as to meet together and form a solid block, as is now well understood.—Patent abandoned.

1682 W. TRIBE. *Improvements in velocipedes or manumotive or pedomotive carriages.* Dated June 7, 1867.

According to this invention the power exerted by the operator is so utilized as to compress or coil a helical spring or springs.—Patent abandoned.

1683 R. SCOTT, jun., J. NIXON, and J. BEAUMONT. *Improvements in the manufacture of certain descriptions of woollen cloths.* Dated June 7, 1867.

This invention relates more particularly to that description of goods known as "tweeds," the object being to produce a clouded, speckled, spotted, or variegated appearance on the face of the cloth. This is effected by making the yarn in a peculiar manner. The clouded appearance is produced by placing in a carding engine two or more slivers of different colours side by side on the "back" or bank" of the machine.—Patent abandoned.

1684 J. WARBURTON. *Improvements in apparatus for registering and recording the quality of gas.* (A communication.) Dated June 7, 1867.

The inventor introduces in the exit pipe a platinum disc, with a fine hole in it, through which the gas passes. Other clocks work arrangements for recording the passing gas. Cannot be described without drawings.—Patent completed.

1685 J. HORTON. *Certain improvements in the manufacture of flyers employed in spinning and twisting fibrous materials.* Dated June 8, 1867.

This invention relates to the manufacture of such flyers as are called "tube flyers," and are principally employed in such machines as "roving," "slubbing," "intermediate," and "Jack frames," and the invention is designed to form the tubular leg or legs of such flyers in such a manner as to obviate the usual tendency of the tube to crack or split in the direction of its length, whilst being curved into a tube from a flat surface.—Patent abandoned.

1686 H. PARKER. *Improvements in the construction of tobacco pipes.* Dated June 8, 1867.

This invention cannot be described without reference to the drawings.—Patent completed.

1687 F. GLISENTI. *Improvements in the manufacture of gun barrels.* Dated June 8, 1867.

This invention consists in manufacturing gun barrels by casting in a suitable mould a strong hollow cylinder of cast steel, which is then drawn out into a tube of the required length and size over suitable mandrils, and between suitable rollers, which tube is now put in the lathe, carefully centering it in respect to its bore, and then turning the outside true cylindrically.—Patent abandoned.

1688 J. COLLIER, R. HOWARTH, and W. CRYER. *Improvements in machinery for knitting healds.* Dated June 8, 1867.

This invention relates to the "healds" or harness used in looms for weaving, and consists in a novel method of forming two or more "healds" or eyes simultaneously, whereby a saving is effected in the time usually required to make a complete set of healds.—Patent abandoned.

1689 J. C. RALSTON. *Improvements in machinery or apparatus for making candles by dipping, and in the self-feeding of the tallow vessel or mould thereof.* Dated June 8, 1867.

This invention is carried out as follows:—The dipping apparatus is mounted in a suitable framing, at one end of which there is a large drum turning in bearings at the upper part of the framing. A rake is dipped or suspended from the drum by belting attached to the same, and provided with a counterpoise. The rods from which the wicks are suspended are placed in blocks, each set of blocks being successively lowered by the dipper into the tallow mould at the lower part of the apparatus, by rotating the drum by the aid of straps passing over pulleys mounted on its axis at either side of the framing. The rake or dipper carrying the rods and wicks is then raised out of the mould by turning the drum in the contrary direction, a sliding frame pushing each set of blocks with rods and wicks from the rake or dipper through grooves made in the upper stages of the framing on to a dropping frame at the opposite end of the machine. The sliding frame is provided with counterbalance weights, and is actuated by a belt passing around a small drum to a second sliding frame placed in a line with the grooves of a lower stage at the other end of the apparatus; the said drum is mounted in bearings on the framing, and is provided with toothed gearing operated by a winch handle.—Patent completed.

1690 H. WILLIS, G. RICE, and A. MAXFIELD. *Improvements in sewing machines, and in apparatus connected therewith.* Dated June 8, 1867.

Among the features of this invention are the following: —It consists, first, of the following arrangements for driving sewing machines worked by hand, which arrangements may also be applied to driving sewing machines worked by the foot. The inventors make the driving wheel with an internal rim, which may either be rough or smooth, and on the shaft to be driven is a pulley, the periphery of which is covered with india-rubber or other substance which, when the pulley is pressed against the interior of the rim of the driving wheel, will produce sufficient friction to cause the pulley to take motion from the driving wheel. In order to produce a sufficient degree of friction between the driving wheel and pulley, the axle of the driving wheel is made to work in a slot, so that it can be pressed with greater or less force against the pulley, and thrown into and out of gear at pleasure. Or they fix a ring of india-rubber, or other substance capable of producing sufficient friction, on the internal surface of the rim of the driving wheel. The working surfaces of the driving wheel and those of the pulley may either be plain or bevilled, but by preference they make them bevilled. The improvements include further arrangements for producing the motion of the needle. Also, further, in making the rotating shafts work in centres or conical bearings, instead of the usual cylindrical bearings; and, further, in arranging the parts of the machine so that it will produce three different kinds of stitch at the pleasure of the operator.—Patent abandoned.

1691 J. HARGREAVES. *Improvements in obtaining motive power.* Dated June 8, 1867.

The patentee claims the use of the waste gases from blast and other furnaces to form with atmospheric air or oxygen an explosive mixture, and the employment of the said mixture to provide motive power by its explosion within any suitable engine, as described.—Patent completed.

1692 J. TURNER and R. B. DUNNETT. *An improved stamping machine.* Dated June 8, 1867.

This invention relates to a machine for stamping or impressing devices or characters on paper and other fabrics and substances in ink or colours, or in sunk or raised characters, and to that class thereof in which the die and the handle by which it is moved are made to describe a curve in passing from the inking or colour pad, or place of rest, to the part where the fabric or substance is stamped or receives the impression.—Patent completed.

1693 O. BARRETT and H. LEGGOTT. *An improved knife cleaner.* Dated June 8, 1867.

In performing this invention the inventors employ one, two, or more cylindrical brushes, which they enclose in a box or casing of suitable size and form, and mount in bearings so as to be capable of rotating therein. In the construction of these brushes, strips of leather, buffalo hide, or other suitable substance, is introduced betwixt the bristles, and in some cases they introduce metal springs to support the said leather or other substance. Also, at or near one end of each brush they form a groove or space to receive a thin diaphragm or partition which forms a division in the box or casing and the brush, one part for cleaning the blade and the other the hilt of the knife.—Patent abandoned.

Digitized by Google

1694 N. THOMPSON. *Improvements in unions or apparatus for connecting together pipes or tubes, and for stopping the ends thereof.* Dated June 8, 1867.

For the purposes of this invention the inventors employ a socket open at each end, and containing within it a packing consisting of a short length of india-rubber tube, or other suitable material. The ends of the two pipes or tubes to be connected are butted together at or near the centre of the socket, and within the packing, into which the ends of the pipes or tubes are just able to enter loosely; the packing is then compressed so as to make it fit closely both to the pipes or tubes, and also to the socket, and so a tight joint is made.—Patent abandoned.

1695 A. PARKES. *Improvements in ornamenting surfaces of paper, woven fabric, and other material, to render them suitable for bookbinding, and other similar uses.* Dated June 8, 1867.

This invention consists, essentially, in embossing the paper, fabric, or material, so as to form on the surface numerous small hollows or undulations and then coating the surface with a thin varnish consisting of dissolved pyroxyline or parkesine and fish scale lustre.—Patent completed.

1696 B. E. PEPYS and J. WARBURTON. *Improvements in apparatus for securing cords and straps, such as are used for raising and lowering window blinds, ventilators, carriage windows, and for other similar purposes.* Dated June 8, 1867.

This apparatus consists of a plate or base which is fixed in an upright position at the side of the window, or otherwise, as may be required. On the plate or base are guides through which the cord or strap is passed to keep it in its place in the apparatus. There is, also, on the plate or base, a bracket to which a movable plate is hinged, and it has fixed to it a weighted handle, and this weight, in hanging down and tending to place itself vertically under the hinge or joint, presses the edge of the movable plate with which it is connected up towards the fixed plate or base, and the cord or strap becomes pressed between the two, with the movable plate nearly, but not quite, horizontal.—Patent completed.

1698 J. CROMPTON. *An apparatus for and mode of revivifying malt liquors and other beverages, and for warming them.* Dated June 10, 1867.

This invention has for its object to revivify malt liquors and other beverages when they have become flat or stale, and the apparatus employed for the purpose consists of a pump, the piston of which is moved up and down, or to and fro, by a lever or handle, a fine spout or nozzle being connected to the pump. The liquor to be revivified is placed under the nozzle, and by moving the handle a portion of it is drawn into the pump. The vessel containing the liquor is then held below, and at some distance from the nozzle, and by again moving the handle the liquor so withdrawn and fresh air are forced into the liquor in the vessel, thereby restoring the briskness to, and putting a head or froth on, the liquor. An elastic ball or other equivalent may be used instead of the pump above referred to.—Patent abandoned.

1699 W. FRENCH. *Improvements in roughing horses and other animals.* Dated June 10, 1867.

For this purpose, in addition to the ordinary nail holes, the patentee forms the shoes with tapered holes of a triangular or other suitable shape, one of such holes being in each heel, and likewise at various other parts of the shoe, and the holes are to be made in an oblique direction, so as to come out at the outer part of the upper edge of the shoe, so that the ends of the stud nails may be hammered down against the shoe.—Patent completed.

1700 J. MACINTOSH. *Improvements in the application of plastic and fibrous materials to the manufacture of moulded or formed articles.* Dated June 10, 1867.

In performing this invention the inventor saturates or coats felt, or other fibrous material, with paraffin, stearic acid, or the pitchy residuum obtained when distilling paraffin or other vegetable substances in a melted or plastic state by any suitable means. The felt or other fibrous material so treated, on cooling, has its fibres cemented firmly together, and is waterproof. When warm, it can be pressed into any form or shape, which it retains on cooling, and may be increased to any thickness by the addition of fresh layers.—Patent abandoned.

1701 T. ROBINSON and J. PIERCE. *Improvements in apparatus employed in the manufacture of zinc.* Dated June 10, 1867.

The inventors employ horizontal retorts of ordinary size, and set and heat them in the usual way; but instead of leaving the inner part of each one at, near, or in the mouthpiece in front of the charge, horizontally or nearly so, they insert or form a baffle piece, the top of which is of about the same level as the charge of ore or other material in the retort.—Patent abandoned.

1702 A. L. DOWIE and R. M'INTYRE. *Improvements in apparatus for punching, cutting, and embossing.* Dated June 10, 1867.

One important feature of this invention is the punching or cutting out of a label, ticket, or other article from sheets of paper, metal, or other material by a plunger which is both a punch and an embossing die, in combination with a duplex resisting piece having raised parts for the punching action, and depressed parts for the embossing action (or *vice versa*), the depressed parts being by preference movable so as to be elevated by springs or positive movements to throw out the embossed article on the die being raised. Another feature of novelty consists in combining with the embossing details a pair of rollers actuated therefrom, and having cutting rims or flanges for cutting the sheets into strips, and at the same time feeding it forward to the embossing die.—Patent abandoned.

1703 J. H. KERLY. *Improvements in fastenings for brooches.* Dated June 10, 1867.

In performing this invention the inventor provides a safety catch, by the aid of which the tongue is prevented from escaping from the fastening. On securing the brooch, the tongue is first depressed so as to slip under a catch which is bent up at its point to facilitate the entrance of the tongue, this action at the same time depressing a spring catch jointed to the brooch plate on the opposite side which is constantly pressed upwards by a small spring.—Patent abandoned.

1704 F. B. DEEBING. *Improvements in engines for boring rock, cutting coal, and boring, cutting, or working in other materials, and in stands or frames for such engines, the improvements in engines being partly applicable to other purposes.* Dated June 10, 1867.

This invention is not described apart from the drawings.—Patent completed.

1705 J. CONOLLY. *Improvements in machinery or apparatus for obtaining motive power, and applying the same to vehicles on common roads, and to other useful purposes.* Dated June 10, 1867.

In performing this invention the inventor proposes to employ a series of cog wheels set on shafts, and in bearings in the sides of a fore carriage, which may be made with a carriage or truck behind for the conveyance of passengers or goods; or it may be made separately, and attached to such carriage or truck.—Patent abandoned.

1706 T. HOLT. *Improvements in the construction of steam boilers.* Dated June 10, 1867.

This invention consists in the use of a novel arrangement of flattened tubes or chambers which form the passages or flues for the flame and heated gases to pass through.—Patent completed.

1707 W. ORR. *Improvements in machinery or apparatus for separating liquids or moisture from substances, and also for revivifying and cooling animal charcoal and other substances, and for treating sugar.* Dated June 10, 1867.

The patentee claims, first, the general arrangement and construction of centrifugal machines, as described, or any mere modification thereof. Second, the special internal arrangement of the centrifugal machine for the purpose of throwing the substance to be desiccated against the baskets after passing through the revolving top plate, substantially as described. Third, the construction of baskets with open bottoms through which the substance falls out when desiccated, as described. Fourth, the construction of centrifugal machines, so that the contents are discharged therefrom on a diminution of the centrifugal force, but without stopping the rotation of such machines, as described. Fifth, the construction of fire clay retorts in short lengths in combination with metallic ends (as shown in the drawings) to be used in connection with kilns as at present usually constructed. Sixth, the mode of supporting fire-clay retorts by means of bars built into or supported by the walls (as shown in the drawings). Seventh, placing the slabs (as shown in the drawings) in charcoal kilns in such a position that deposits of soot may fall down the internal surface and accumulate in the box for removal (as shown in the drawings). Eighth, the use of downward printing slabs forming the roof of the furnace for the purpose of dividing the ascending currents of heat, and throwing them into the chambers on either side, in combination with kilns constructed under this invention. Ninth, the placing of a flat top boiler over the flue of charcoal kilns for the purpose of drying the charcoal previous to its being placed in the retort; also for supplying hot water to the centrifugal machine. Tenth, the barrow with water spaces for rapidly cooling the charcoal, and to be used in connection with kilns as at present or otherwise constructed. Eleventh, the use and application of scoops, ploughs, or loose hinged projections or trails attached to the agitators of the "blow up," for the purpose of preventing the accumulation of undissolved matter in the lower part of the vessel or pan. Twelfth, the application of the special arrangement (as shown in the drawings) of valve to the sugar "blow up" or meeting pan, having the stuffing box as a fulcrum for the spindle acted upon by the sliding weighted bearing in the bracket. Thirteenth, the internal arrangements of the bag filter or cloth filter, so that the bags are kept floating in the liquid with a slight pressure, whilst the dirt is conveyed out of them. Fourteenth, the method described of cleaning the bags without unpacking the filters. Fifteenth, closing the communication between the bags and sludge chamber by means of valves, so that the sludge may be removed without emptying the bags. Sixteenth, heating solid solutions through pipes in a steam chest before being run into the charcoal. Seventeenth, superheating sugar solutions through pipes in a steam chest before entering the vacuum pan.—Patent completed.

1708 R. LOGAN. *Improvements in securing and adjusting windows, blinds and shades, doors and shutters, and in the apparatus employed therefor.* Dated June 10, 1867.

This invention relates to the regulation of the opening of blinds, and consists in employing one or more racks having ratchet teeth on them, which racks are attached to some convenient part of the framing. The movable part of the window blind, shade, shutter, or door has one or more ratchet palls fixed to it, and which is or are acted upon by a spring, and by it forced into the recesses of the teeth.—Patent completed.

1709 R. HORNSBY, J. BONNALL, and H. SHIELD. *Improvements in thrashing machines and other machines for dressing and separating grain, and in rotary screens to be used therein, and for other purposes.* Dated June 11, 1867.

In thrashing, dressing, and separating machines the sieves or riddles over which the grain is passed have a short vibratory or shaking movement communicated to them, and to admit of this the sieves or riddles are hung by means of links or hangers capable of turning on studs or pins; this, however, involves the use of a great number of centres, which require lubrication. According to this invention, a tube of vulcanized india-rubber is placed on each of the studs or pins, and the eye of the link or hanger is made sufficiently large to receive the india-rubber tube within it; then, when the link or hanger is in its place, the india-rubber is compressed by means of a nut screwed on the end of the stud or pin, which causes the india-rubber to bind tightly both to the stud or pin and to the interior of the eye of the link or hanger. The elasticity of the india-rubber tube will then allow sufficient movement of the link or hanger around the stud or pin without any friction or rubbing taking place between the parts. With cylindrical or rotary screens for thrashing, dressing, and separating machines and other uses, it is desirable to be able to increase or diminish the spaces between the wires, so as to make the screen either coarser or finer, as may be required, by stretching or compressing the cylindrical or rotary screen longitudinally. According to this invention, the circumferential wires are bound to other wires or rods, as in an ordinary screen, but in place of arranging these wires or rods to pass direct from end to end of the screen, they are arranged in a helical direction, so as to pass partly or entirely around the screen as they run from end to end of it. This invention cannot be fully described apart from the drawings.—Patent completed.

1710 H. A. BONNEVILLE. *Improvements in vessels, more particularly such as are used for the reception or deposit, or both, of offal, excrement, urine, or other fecal or waste matter or substance.* (A communication.) Dated June 11, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

1711 C. TOFT. *Improvements in cruet frames, liquor frames, pickle frames, and other frames for holding bottles and vessels, and in the bottles and vessels to be held in the said frames.* Dated June 11, 1867.

The patentee makes in the body of the bottles or vessels to be held in the frame an annular groove or depression, the said groove being deepest at its middle. The neck is thereby formed a shoulder on the bottle or vessel, by means of which the bottle or vessel is supported in the frame. Patent abandoned.

1712 J. GRAHAM. *An improved mixture or composition for bleaching vegetable fibres.* Dated June 11, 1867.

The patentee claims mixing salt, treacle, and lime with black soap so as to form a mixture or composition as described for bleaching vegetable fibres, as described.—Patent completed.

1713 H. FLETCHER. *Improvements in the manufacture of artificial fuel.* Dated June 11, 1867.

The patentee manufactures this artificial fuel from "slack" or small coal mixed with pitch, or other adhesive material. The coal may be made dry and hot before the pitch or other adhesive material is added, and the heated compound is ground, granulated, or pulverized, and then thoroughly admixed simultaneously in a suitable machine. The admixed material is then reheated to render it more adhesive, and afterwards it is put into moulds and pressed into blocks. Or the coal may be used in a cold state and the pitch or other adhesive material added.—Patent completed.

1714 J. H. JOHNSON. *Improvements in rolling and shaping metals, and in the machinery or apparatus employed therein.* (A communication.) Dated June 11, 1867.

This invention relates to a peculiar combination and arrangement of rolling mill for rolling X-shaped and other forms of pillars, guides, or bars. According to this invention, four rolls are employed of any desired form, according to the shape of the article to be produced. The top and bottom rolls are driven in the usual or other convenient manner; whilst the other pair of rolls, which revolve horizontally, and are situate on each side of a central vertical plane, which passes transversely through the top and bottom rolls, are rotated solely by friction contact with the metal to be rolled. After each pass of the metal, the top roll, and two horizontal rolls are moved inwards slightly by means of powerful adjusting screws, or other suitable mechanical contrivance, so as to nip the metal equally on all four opposite sides. The horizontal rolls are contained in strong movable frames or supports, which are capable of sliding vertically at the main standards or frames of the rolling mill, so that as the top roll is lowered, the two horizontal rolls are not only be made to approach each other, but to descend slightly, in order to keep them always in a central position between the top and the bottom rolls.—Patent complete.

1715 G. P. HILL. *Improvements in boxes, drawers, and other like receptacles.* Dated June 11, 1867.

This invention relates to boxes for holding trimmings and other fancy goods, and consists in so constructing them that a portion of the contents of the said boxes (sufficient for commercial or trading purposes) may be exhibited to view when the said boxes are closed.—Patent abandoned.

1716 J. THOM. *Improvements in apparatus to be employed in expressing oils and fatty matters.* Dated June 11, 1867.

This invention relates to a former patent granted to the present patentee, dated December 1, 1863 (No. 39), whereby a saving in the wear and tear of bags is effected and a larger quantity of oil is expressed from the same amount of oil-yielding substance. The patentee makes the raised or bevilled sides of his pressing plates or faces of such a width that when the bag is bulged outwards laterally by the pressure thereon, the edges of the plates will, by reason of their increased width, have a tendency to cut or or injure the bags.—Patent complete.

PROVISIONAL PROTECTIONS.

Dated September 7, 1867.

2538 J. and T. Bayley, jun., Lenton, Nottingham, leather dresser. Improvements in the manufacture or production of leather.

Dated October 14, 1867.

2834 M. Fitzpatrick, Duke-street, Lincoln's Inn, engineer. Improvements applicable to railway trains for the prevention of accidents arising from collisions or other casualties on railways.

Dated October 18, 1867.

2926 J. Hill and S. Shelley, Manchester. Improvements in looms and in the method or process of preparing weft that will enable the plain loom to weave check or stripe goods.

Dated November 22, 1867.

3506 R. Leighton, Shoe-lane, City, bookbinder, and T. Kirkham, Cambridge Villa, Gilston-road, West Brompton, civil engineer. Improvements in the method of sewing sheets of paper forming books and pamphlets, and in machinery for effecting the same.

Dated December 12, 1867.

3537 A. V. Newton, Chancery-lane, mechanical draughtsman. An improved method of manufacturing cast steel and malleable iron. (A communication.)

Dated December 13, 1867.

3553 L. Christophe and J. Montigny, Brussels, mechanicians. An improved tubular cannon for firing volleys or charges of grape shot.

Dated December 16, 1867.

3578 W. Jackson and J. Dyer, Birmingham. Improvements in the construction of valves and valve cocks.

Dated December 18, 1867.

3601 H. A. Bonneville, Porchester-terrace, Bayswater. An improved apparatus to manufacture the rims of hats. (A communication.)

Dated December 20, 1867.

3622 G. Davies, Serle-street, Lincoln's Inn. Improvements in circular knitting machines. (A communication.)

Dated December 24, 1867.

3656 C. Pottinger, Anstruther, Fifeshire, shipbuilder. Improvements in motive power engines, part of which improvements are applicable to the arrangement and construction of pumps for raising and forcing liquids, fluids, and other substances generally.

Dated December 26, 1867.

3668 J. Lightfoot, Lower House, Burnley, Lancashire, chemist. Improvements in printing certain textile fabrics and yarns.

3669 N. Greenhalgh, Sharples, W. Shaw, Heaton, cotton

Digitized by Google

spinners, and J. Mallison, Halliwell, yarn agent. Improvements in steaming certain yarns, and in apparatus employed therein.

3671 E. C. Jetot, E. Hortensius, C. Cros, and M. M. A. d'Eimar de Jabrun, Rue Royale St. Honore, Paris. A hat protector or apparatus for preserving hats and caps from rain, dust, or otherwise.

Dated December 27, 1867.

3673 J. Edge, Tipping Iron Works, Bolton-le-Moors, Lancashire, engineer. Improvements in the rag-rolls or beaters of rag-engines, beating-engines, or other similar machinery employed in the manufacture of paper.

3675 T. J. Ellis, Abingdon-street, City, civil engineer. Improvements in the construction and arrangement of apparatus for carburetting gas and atmospheric air.

3677 J. M. Rowan, Glasgow, engineer. Improvements in moulds or apparatus to be used in casting steel.

3679 H. Higgins, Salford, machine maker, and T. S. Whitworth, manager. Improvements in machinery for preparing, spinning, and doubling cotton and other fibrous materials.

3681 A. V. Newton, Chancery-lane, mechanical draughtsman. Improvements in soles for boots and shoes. (A communication.)

3683 A. Dunn, White-street, Southwark, and A. Liddell, foreman. Improvements in the manufacture of metallic casks or vessels.

Dated December 28, 1867.

3685 J. Goodfellow, Atlas Works, Blackburn, engineer. Improvements in metallic pistons for steam cylinders, air cylinders, or pumps.

3687 W. Fryer, Birmingham, plumber. Improvements in self-closing taps.

3689 W. E. Newton, Chancery-lane, civil engineer. Improvements in butt hinges. (A communication.)

3691 C. Morfit, Sudbrook Park, Surrey. Improvements in means or apparatus for cutting soap.

3693 L. Hasluck, Tottenham-court-road, watch maker. A mechanical tell tale, alarm, printing, and reporting clock.

3695 J. Jowett, Parkhead, Lanarkshire. Improvements in furnaces.

Dated December 30, 1867.

3697 J. E. Gowen, Langham Hotel, Portland-place. An improved mode of and means for raising sunken vessels.

3699 T. and J. Robertshaw, Ovenden, near Halifax, spinners and manufacturers, and J. Greenwood, overlooker. Improvements in looms for weaving.

3701 G. Glover, Ranelagh-road, Pimlico. Improvements in lamps or apparatus for burning naphtha, benzole, and similar liquids to represent a candle. (A communication.)

3703 J. Aschermann, Paris, manufacturer. An improved machine for cutting the hair or fur from skins, for hat-making and for the manufacture of felt.

Dated December 31, 1867.

3706 M. A. F. Mennons, Southampton-buildings, Chancery-lane. Improvements in the mode of and apparatus for combining the vapours of liquid hydrocarbons with oxygen and hydrogen, and burning the mixture as fuel. (A communication.)

3707 M. A. F. Mennons, Southampton-buildings, Chancery-lane. The manufacture of a vegetable substitute for animal hair from a product not hitherto used for that purpose. (A communication.)

3708 M. A. F. Mennons, Southampton-buildings, Chancery-lane. An improved mode of accelerating the induration of certain descriptions of concrete or artificial stone. (A communication.)

3709 T. Messenger, Marine Department, London, Chatham, and Dover Railway, Dover, engineer. Improvements in the construction of steam engines and boilers.

3710 G. McCulloch, Manchester. Improvements in thread-polishing machines.

3711 W. Barnes, Worcester, commercial traveller. Improvements in carriage lamps.

3713 V. L. Daguzan, Rue Sainte Appoline, Paris, painter. Improvements in the construction of paving.

3714 H. Bessemer, Queen-street-place, Cannon-street. Improvements in the treatment of crude or cast iron, and in the manufacture of malleable iron and steel.

3715 C. G. Hill, Alfred-street, Nottingham. Improvements in the preparation of floss silk and in the manufacture of ruches.

3716 W. Wilson, Newcastle, hat manufacturer. Improvements in the manufacture of hats and other felted articles of wearing apparel, and in machines employed for these purposes. (Partly a communication.)

3717 N. Smith, Kingston-upon-Hull, joiner. Improvements in stoves.

3718 A. Allan, Bower Bridge, Cumberland. Improvements in brakes applicable to carriages and other vehicles.

3719 J. H. Johnson, Lincoln's Inn-fields. Improvements in machinery or apparatus for spinning cotton and other fibrous materials. (A communication.)

3720 A. M. Clark, Chancery-lane. Improvements in road-sweeping machines. (A communication.)

3722 W. and T. Mitchell, Stacksteads, Lancashire. Certain improvements in carding engines to be employed in the process of manufacturing felt carpeting.

3723 J. G. Crompton, Stockport, leather manufacturer. Improvements in mechanism or apparatus to be employed in the manufacture of felt hats.

Dated January 1, 1868.

2 W. R. Lake, Southampton-buildings, Chancery-lane, consulting engineer. Improvements in fire and burglar proof safes. (A communication.)

5 W. Stroudley, Inverness. Improvements in re-railing or replacing carriages or waggons on rails of railway.

6 W. and J. W. Wood, of Monkbill, Yorkshire. Improvements in the manufacture of cardings and yarns.

8 H. Milward, Redditch, needle and fish hook manufacturer. Improvements in needle cases. (A communication.)

9 R. W. Morrell and P. Craven, Bradford. Improvements in machinery or apparatus for spinning and doubling fibrous substances.

10 W. J. Fraser, Commercial-road East, engineer. Improvements in furnaces or fireplaces.

11 J. Imray, Westminster Bridge-road, engineer. Improvements in locomotion.

13 A. Beard, Alyn Vale, Gwersyllt, Denbigh, ironmaster. Improvements in furnaces and firebars.

14 T. B. Daft, Cleves Lodge, Church-street, Chelsea, civil engineer and naval architect. Improvements in the construction of iron ships and vessels,

15 J. Ramsbottom, Leeds, engineer, and T. M. Pearce, Bradford, commission agent. Improved engines and generators for the same, to be worked by heated air, steam, or other gases or vapours.

16 B. Vette, Berlin. Improvements in the manufacture of "crossovers," scarves, and other articles of apparel known as frame and knitted woollen goods.

17 D. Foster, Sheffield, engineer. Improvements in the manufacture of anvils (of all kinds) for smiths, and every description of top and bottom faces for hammers for drawing-out purposes.

Dated January 2, 1868.

18 M. A. Hamilton, Southampton-buildings, Chancery-lane. An improved churn.

19 E. J. and W. A. Kruss, opticians, Hamburgh. A new or improved camera or lantern for reflecting opaque objects.

20 E. Izod, Grocers' Hall-court, City. Improvements in the finishing of stays, and in means or apparatus employed therein.

Dated January 3, 1868.

21 J. Cox, Birmingham, electro-plate and gilder. Certain improvements in fastenings for sleeve-links, which said improvements are also applicable to the fastening of brooch pin points, belt and other clasps, gloves, stay, and legging busks, and other dress and jewellery fastenings.

23 T. P. A. Key, Clifton Mount, Rotherham. Improvements in scaffolding to be used for the erection of houses in the streets of populous places.

25 J. D. and B. Dellagana, Shoe-lane, City, printing machine makers and stereotype founders. Improvements in printing machines, and in the manufacture of electrotype blocks to be used in such machines.

26 M. E. Roy, Upper Norwood, and Lonisa Prevett, Penge, Surrey. An improved receptacle for containing needles, thread, and other articles.

Dated January 4, 1868.

28 J. T. Emmerson and J. Murgatroyd, Heaton Norris, Lancashire, millwrights and engineers. Improvements in the manufacture of iron, and in the application thereof to certain useful purposes.

30 W. J. Blinkhorn, St. Helen's, Lancashire, candle manufacturer. Improvements in the manufacture of snuffless dip candles, and in apparatus employed therein.

31 W. E. Newton, Chancery-lane, civil engineer. An improved mechanical arrangement for converting power into speed, and speed into power, and for multiplying and transmitting motion for all purposes where such movement can be applied and used. (A communication.)

32 P. Spence, Newton Heath, Manchester, manufacturing chemist, and W. A. Smith, Manchester, merchant. Improvements in storing meat for transport, whereby it may be preserved, and in apparatus connected therewith.

33 W. H. Atkinson, Aldersgate-street, City, manufacturing chemist. Improvements in the preparation and use of compositions for cleansing and sweetening casks and other vessels, such compositions being also applicable to other purposes.

34 A. Albini, New Broad-street-buildings, City, Italian Navy. Improvements in cartridge belts or pouches.

35 W. B. Gray, Whiteabbey, Antrim. Improvements in spinning and twisting machines.

36 G. Mudge, High-street, Notting-hill, ironmonger. Improvements in adjustable lock furniture.

37 J. Nixon, Westbourne-terrace, Middlesex. Improvements in apparatus for transferring coal or minerals from railway waggons into barges.

Dated January 6, 1868.

39 E. R. Southby, Lanark, chemist. Improvemnnts in separating paraffin from its solutions, and in apparatus therefor.

41 T. Stokes, Kidderminster. Improvements in the manufacture of piled fabrics in imitation of the fleece or fur of animals

42 J. R. T. Mulholland, Belfast. An improved construction of "creel" or bobbin-holder.

44 F. Chamberlain, Bredecot Court, near Worcester, engineer. Improvements in steam boiler and other furnaces.

Dated January 7, 1868.

49 C. Hutchinson, Tufnell-park-road, Holloway. An improved liquid metre tap.

51 H. McEvoy, Birmingham, manufacturer. Improvements in fastenings for drapery, articles of dress, or wearing apparel.

53 W. T. Tongue, Wolverhampton, factor. Improvements in lamps for burning paraffin and other hydrocarbon oils.

55 G. Smith, Liverpool, brass and Britannia metal finisher. Improvements in apparatus for lubricating machinery.

57 H. Smyth, Little Trinity-lane, City, manufacturer. Improvements in umbrellas, parasols, and sunshades.

59 G. Davies, Serle-street, Lincoln's-inn. Improvements in the mode of combining wrought and cast-iron or other metals for various useful purposes. (A communication.)

61 J. L. Norton, Belle Sauvage-yard, Ludgate-hill, City, and W. H. Bailey, Albion Brass Works, Salford, brass founder and steam gauge manufacturer. Improvements in apparatus for indicating and recording the fluctuations of the pressures and temperatures of liquids and fluids.

63 G. E. Donisthorpe, Leeds, engineer. Improvements in the construction and mode of fixing joints, catches, or other fastenings for brooches and other ornaments, and ornamental mountings and fittings for furniture and articles of vertu.

65 B. J. Heywood, Lorraine-road, Holloway. An improved construction of coffee roaster.

PATENT APPLIED FOR WITH COMPLETE SPECIFICATION.

Dated January 9, 1868.

90 O. H. M'Mullen. An improved mashing machine

2608 P. Dumont. Soap. (A communication.)
2615 T. Turner. Mounts for maps.
2619 D. Gardner. Mattresses.
2625 T. Adams and G. J. Parson. Slide valves.
2641 W. Potts. Ventilating rooms.
2645 F. T. M. A. Guyon. Typographic apparatus.
2664 J. Baird. Treatment of jute.
2683 A. M. Clark. Boots and shoes. (A communication.)
2701 W. Woodcock. Warming buildings.
2710 A. Taylor. Ornamental fabrics.
2717 E. T. Horsley. Production of a glazed surface on cast iron.
2739 J. H. Johnson. Railway wheels. (A communication.)
2799 J. H. Johnson. Braid. (A communication.)
3164 G. T. Bousfield. Setting types. (A communication.)
3192 G. T. Bousfield. Machines for sewing fabrics. (A communication.)
3207 J. D. Scally. Treating casks.
3235 G. R. Solomon, jun. Ticket register.
3358 A. V. Newton. Making extracts from bark. (A communication.)
3363 S. A. Chase. Carriage trucks.
3406 S. Sharrock. Posts for electric telegraphs.
3602 M. H. Collins. An improved lamp.
3624 L. L. Tower. Faucets for measuring liquids. (A communication.)
3633 J. Davidson. Machinery for manufacturing cartridges.
3662 W. E. Newton. Alcohol meter. (A communication.)
3665 S. and F. Lennard. Warp fabrics.
3697 J. E. Gowen. Raising sunken vessels.
3715 C. G. Hill. Floss silk.
3722 W. and T. Mitchell. Carding engines.
27 M. J. Frisbie. Feeding fuel into furnaces.
31 W. E. Newton. Converting power into speed. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

50 T. Richardson and M. D. Rucker
125 T. Bourne
137 J. Betteley
141 F. H. Lakin
142 S. J. Best and J. J. Holden
143 J. Robinson and J. Smith
144 C. T. Judkins
147 W. Jeffreys
154 J. Coulter and H. Harpin
152 W. E. Newton
155 W. R. Foster
160 M. B. Mason
161 E. D. Farcot
165 J. A. Shipton and R. Mitchell
170 D. Munro and T. Wright
173 J. Hewes
180 W. Clay
189 M. Robinson
197 J. B. Wood
418 A. Fryer

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

152 C. W. Lancaster, J. Brown, and J. Hughes
167 C. W. and F. Siemens
175 J. Chatterton and W. Smith
185 W. Wilson

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, JANUARY 31, 1868.

PATENT CASES IN THE COURT OF CHANCERY.

THERE is perhaps no branch of our jurisdiction which more requires reform than patent jurisdiction. A patent is neither more nor less than a right granted to an inventor, in return for the disclosure of a new process, to bring an action against an infringer. The mode in which patent cases are tried will therefore give the tone to the entire working of the law. It is this defective mode of trying such cases that originated the outcry a few years ago against patents; and though the public may be held to have been convinced of the necessity for protecting inventions, yet a defective patent jurisdiction can be regarded as a standing danger to the very existence of patent rights. Nothing less than a radical reform, embodying a rational infusion of the technical element—either by means of scientific assessors, or by a jury of experts—will really suffice. In the meantime, however, we feel bound to notice, with that impartiality which is true friendship to the whole body of inventors, what we consider a most injurious course on the part of the Court of Chancery. The late decision of Lord Cairns affirms an order of the Master of the Rolls that a defendant in a chancery suit has no right to require that the questions of fact involved in the litigation shall be tried by jury. It seems inexplicable to us that any court should refuse such an application made by a defendant. It would have been intelligible had the plaintiff made the application, for he had the choice of the tribunal, and the court might fitly have marked its reluctance to lend itself as a mere instrument for the enforcement of the private rights of any patentee, by not affording him facilities for the trial of his cause otherwise than according to the usual course of the court. But when it is the defendant who makes the application, and when it is made to a branch of the court which may be known to have a very strong conviction upon the subject of the patent, the refusal—to be justifiable—must be based upon views of the rights of patentees and the disabilities of defendants, which, if indeed they exist in chancery, form a sufficient reason for putting an end to the jurisdiction of that court in respect to patents. We may here remark that there must be some great inducement to patentees to resort as they now do to Chancery rather than to the common law courts. The hitherto uninterrupted success of Betts' patent in Chancery, contrasted with its chequered career during the litigation in Betts v. Menzies; the equally marked success of Bovill's patent in Chancery, and the resistance of that patentee to let the question of fact go before a jury—not to dwell upon the circumstance that one verdict has actually been given against that patent—are significant.

It would be improper to express an opinion as to the merits of these two patents whilst they are still before the courts. It is enough to mention these well-known instances of the better fortune attending patentees in equity than at law. The explanation is simple enough. It is very much in the nature of things that a judge in Chancery, having once heard the evidence offered in one cause upon a patent, and pronounced judgment upon it, should regard his decision upon the evidence in the first case in the same light as he is justified in regarding his decision upon the question of law, namely, as authorization in all future cases until reversed on appeal. So strongly does this feeling operate, that instances have been known of patentees offering terms to the defendant in the first suit upon a patent, to induce him to submit to an injunction, in order that the injunction, thus fraudulently obtained, may be paraded before the public and the court as a decision establishing the validity of the patent. It is wearisome to hear in the Court of Chancery discussions as to what a judge in an earlier case thought of a particular piece of evidence—discussions which, before a jury, would be impossible. Surely, what any body else thought of any given evidence is as irrelevant as the figures in an old almanac.

It is, however, by means of these discussions that a Chancery suit upon a patent, if really heard at all, extends to such portentous proportions. The patentee knows full well what an admirable investment he makes by spending even £10,000 on a successful Chancery suit. What hope can any future defendant have of resisting his pretensions? In order to get the former decision reviewed on appeal he must incur the vast expense of repeating all the evidence which was ineffectual on the previous occasion. He must incur the heavy burden of an injunction and payment of the patentee's full costs in the courts as the price of being at liberty to bring the validity of the patent into effective discussion. Compare this with trial by jury. The proceedings in former litigations are absolutely shut out from consideration; both parties conduct the trial upon equal terms, and twelve men of the world, if not of experience in the manufacture to which the patent relates, give an unbiassed common-sense judgment upon the evidence. There is great and increasing dissatisfaction because a patentee can prevent his antagonist getting the opinion of a jury or of a court of common law upon the patent, because the Court of Chancery seems to regard this protection of the patentee as the principal, if not the sole, object in administering the patent law. It is quite true that a more satisfactory tribunal than a jury for trying a patent cause can be imagined; but it is doubtful whether the Court of Chancery is, at any time, a better one for ascertaining the truth as to the facts. And it is certain that any defendant compelled to try a cause without a jury in a branch of the court in which the patent has already been upheld, cannot do so with any reasonable expectation that the trial will be impartial. In the mean time, any law whatever is practically out of reach of the patentee who is unable to begin a contest involving the expenditure of tens of thousands.

THE ADMIRALTY.

IF we were asked to name that department of the public service which more deeply concerns the honour, safety, and prosperity of this country than any other, and which is probably more flagrantly mismanaged than any other public department at home or abroad, we should have no hesitation in naming the Board of Admiralty. It has never been our practice, nor is it now our intention, to cry "wolf," merely because various other organs of the press are at the present time directing their concentrated fire upon that knot of hapless gentlemen who comprise our Admiralty Board. We write upon this important subject with a full sense of the responsibility resting upon us, and with the sole object of promoting the interests of the public service; we are simply anxious to do all that lies in our power to prevent, if possible, the consummation of a policy—if such it can be called—which we believe to be not only ill-judged and wasteful, but scandalous in the extreme.

It appears to us, and we think it must so appear to every intelligent reader, that our fine fleet of wooden screw frigates and line-of-battle ships has not become absolutely useless to us, in consequence of the introduction of ironclad ships into the Navy. So long as other naval powers have ships of war in their service minus armour-plating, and so long as the merchandize of this and other countries is carried in ships of the description now employed for the purpose, so long will the wooden ships of our Royal Navy be capable of rendering service to this country. Seeing the length of time required for the production of an ironclad ship, and bearing in mind the present numerical weakness of our ironclad fleet, we are of opinion that it would be little short of a criminal policy for the Admiralty to adopt, with reference to our wooden ships, the shameful course of, to quote the words of a contemporary, "simply giving them away in one or two favoured quarters for about the value of their nails."

We, therefore, say, let the sound, serviceable, and modern wooden ships of the British Navy be still retained in the service, and kept in such a forward state as to be capable of taking the sea at the shortest possible notice, for the purpose, should the necessity unfortunately arise, of grappling with the wooden war ships of our enemy, and also for the protection of our mercantile marine in every part of the world. England must have ships for other work than meeting powerful ironclads in line of battle. We may here mention, in support of these views, that we know a distinguished officer of high rank in the British Navy who considers it would not be difficult, but comparatively easy, to take a three turretted ironclad cupola ship with an ordinary 50-gun wooden frigate. But, be this as it may, nothing can be more absurd, more suicidal, than to literally throw away our wooden fleet, because of the introduction of ironclads. We might as reasonably throw or give away all our artillery, except a few of the largest guns recently manufactured. It should be borne in mind that during the late civil war in America the southern ports were blockaded by wooden ships; also, that the "Alabama" was built of wood. We cannot say that we are enamoured of any of the proposals for plating our wooden ships with iron, believing that they cannot be converted into effective sea-going ironclads, not excepting Mr. Henwood's plan, which we have carefully examined, and which we are confident would not realize the satisfactory results claimed for it by its proposer. We believe it to be the wiser policy to keep a good wooden ship as she is, and at her present cost, rather than convert her into a mere makeshift of an ironclad at a greatly increased cost.

Although we thus advocate the retention in the service of our effective wooden ships of war, it is not to be inferred that we are insufficiently alive to the necessity for increasing as rapidly as possible our ironclad fleet. We do not think with a certain eminent ship builder, that it is necessary for England to possess a fleet of ironclads large enough to cope with the combined fleets of every naval power in the world; but we do think it essential that we should possess a fleet sufficiently large and powerful to be able to compete with the fleets of any probable combination of hostile powers. Entertaining these views, it is with deep regret that we contemplate the comparatively small amount that has been devoted during the present financial year to the augmentation of our ironclad fleet. Out of more than ten millions sterling voted for the Navy, the sum of seven hundred thousand pounds only has been appropriated to the construction of ironclad ships. This is a state of things which will assuredly be brought before Parliament on an early day, and we shall be greatly mistaken if, during the next year, twice the amount above named is not applied to the purpose referred to. There must surely be great shortsightedness, something radically wrong, in the disposal of the immense yearly sums voted for our Navy to account for such feeble practical results.

In concluding these remarks, we will refer for a moment to the ship now building at the Thames Ship Building Company's works for

Digitized by Google

the King of Prussia. This fine ironclad ship was originally designed for the Sultan of Turkey by our present Chief Constructor of the Navy, of course with the permission of the Admiralty. This ship is now rapidly approaching completion, and, after a minute personal examination of the ship herself, we are convinced she will, when completed, be the most powerful ironclad yet afloat; but she has been allowed to pass into the hands of a foreign power simply because the authorities at Whitehall could not (?) or would not supply the funds necessary for her purchase. Turkey could not find the money to complete her, and we could not find the funds to purchase her in a half completed condition, the seven hundred thousand pounds before named being all that could be spared out of the ten millions for the increase of our ironclad fleet. This transaction did not take place in the dark; there was no surprise in the case; the ship has been lost to the country for the simple reason that her cost was not provided for at the commencement of the year, and the accounts could not be altered, and she has in consequence been allowed to pass from us. We purpose in a future number to give a full description of this formidable ironclad.

CONSUMPTION OF SMOKE.

THE important question of smoke consumption is gradually obtaining that attention it has long demanded. We have from time to time urged upon the public the folly of not consuming their smoke, and the advantages which accrue where it is consumed. We have also shown how very simple a matter it is to burn the superfluous carbon, and thus relieve our atmosphere from a most unwelcome burthen. The remedy is simple enough, and is well known and appreciated in Cornwall. There, too, the value of coal is known, and this is the secret of the great economy of fuel in that county, and of the consequent smokeless appearance of the chimney shafts. There the engineman whose engine shows the highest duty obtains a premium; so not a pound of coal is wasted, not a puff of smoke is seen, except, perhaps, at the moment of firing. And all this is only due to judicious stoking. Instead of a indiscriminate use of fuel, it is used carefully and sparingly. The coal is fed on to the front of the furnace and there baked, the gaseous products being consumed in their passage over the clear fire behind. The baked coal is gradually pushed to the rear to make room for fresh fuel, and thus we get the high returns of duty from the Cornish engines—that is, those at work in Cornwall. Nor does the benefit stop here; the air is, of course, purified, and the proprietors are pecuniarily benefited by this system of slow and gradual stoking. It will take a long time, we fear, to drill this lesson of practical economy into some of our manufacturers; they will, of course, admit the correctness of its principles, and, perhaps, endeavour to induce their enginemen and stokers to follow out the system, but the chances are they will not succeed. Let them offer premiums for economy, and we believe they will attain their end. Give a man ever so slight an interest in the results of his labour, and he will be sure to use his head as well as his hands, even in the mechanical work of stoking.

Beyond this there are, of course, means open to those who like to pay for them in the shape of smoke consumers. There are also many little dodges in stoking disclosed in practice which can be adopted with some furnaces. For instance, one steam power user leaves his furnace door slightly open, and thus prevents smoke. But steam users ought to be cautious on this point, for the Government smoke inspector insists that all furnace doors shall be closed, and then summonses the hapless wight whose chimney smokes. At least, he did so in one instance, but fortunately the magistrate possessed common sense, and dismissed the summons, and censured the inspector. With regard to mechanical appliances, we may mention that some experiments have recently been carried out in the boiler furnaces at the Shelton Bar Ironworks, Hanley. At first, two furnace doors were fitted up on the Smedley principle. Instead, however, of the doors being made self-acting by attachment to clockwork, they were regulated by the fireman by means of weights, pulleys and chains. Although these doors answered very well, they were found to be unnecessarily expensive and susceptible of improvement. Three other doors on a new principle were, therefore, fitted to as many furnaces. These doors are made thus:—Instead of movable horizontal bars admitting the external air into the furnace through a grating of heated vertical bars, there is a balance door for the admission of the air, which, by means of horizontal louvre bars, is driven direct upon the fire. It is found in practice that there is nothing gained by making the doors automatic. As the fireman must always be in attendance on a set of boilers, he has only to touch the balance weight, by which he can set the door to any desired angle for the admission of the air current. Moreover, by fixing the internal range of bars on the louvre plan, the fuel receives the full force of the oxygen as it rushes in through the open door. It is also found that a door on this principle can be made for about one-fifth the cost of the Smedley door. The results of careful trials have proved so satisfactory that all the boiler furnaces of the Shelton Works are to be fitted on the same plan.

China and earthenware manufacturers have usually been considered as licensed to smoke away as hard as they can, on account of the great difficulty they would have in preventing the emission of smoke from their ovens. It now appears, however, that this difficulty can be surmounted, for we understand that Messrs. Edwards, the earthenware manufacturers of Burslem, have fitted one of their ovens and all their kilns and boilers with Dix's patent smoke-consuming door. In this instance the principle of louvre bars has been adopted, and they are so worked by means of a vertical lever that the supply of air can be regulated at pleasure. In the case of the oven no smoke is produced after the first lighting of the fires. As a point of practical economy it is found that one ton of coal per oven is saved, and that the length of time required for firing an oven of ware is reduced by two hours. The heat can be regulated with the greatest nicety, and thus there is much less waste from over or under firing. This is a very important fact, not only for the trade but for the public, who are always sufferers from the smoke nuisance.

Besides mechanical means, there is the use of different kinds of coal, and some people who can distinguish and appreciate their differences, will use that kind which produces the least smoke. And this reminds us of some experiments which are being carried out by the North London Railway Company with the view of reducing the smoke made by their engines. It is very important that this line should take as little part in the smoke nuisance as possible, for it passes in part through closely populated localities, and its traffic is heavy and frequent. Mr. William Adams, the locomotive engineer of this line, informs us that they are now burning in their locomotives South Wales coal, which is nearly, but not quite, smokeless. They find that when the fires are newly made up, if the blower or jet is not used, some smoke will be formed. The use of this coal has not been of sufficiently long duration to enable an accurate estimate of its economy to be formed as compared with the Derbyshire coal previously used. The price of the Welsh coal is higher than that of the Derbyshire, but a smaller quantity of the former is required, so that the cost of working will probably prove to be about the same as formerly. But, then, great advantages are gained, especially on a line like the North London, for although their engines are fitted with the best known appliances for consuming smoke, a little carelessness on the part of the drivers, in using bituminous coal, will cause a great deal of smoke to form. The adoption of this coal by others would help them over the smoke-consuming difficulty, by giving them no smoke to consume, and although an economy of some hundreds per annum would be a very pleasant thing, they ought to be well satisfied with equal cost with the advantage of getting rid of all complaints about the smoke nuisance.

PEAT FUEL.

WE have noticed during the past week that several contradictory statements have appeared in the "Times" relative to the manufacture of peat fuel, under Mr. C. Hodgson's patents, to which we alluded in our last number, and which was described recently by the President of the Institution of Irish Engineers, and has been contested on the score of want of originality by Messrs. Gwynne, of Essex-street. There is nothing more uncertain or contestible than the facts bearing on the first invention of any useful art or manufacture, and nothing practically of so little importance to the public at large as to be made aware of who was the first enunciator of an idea for the accomplishment of which no practical means were at first brought forward. In the case in point, the abstract idea of compressing peat in a dry, instead of in a wet state, as tried by Wye Williams and many others since, has been erroneously supposed to have originated with Mr. Hodgson, but was never claimed by him; and although now claimed by Messrs. Gwynne, under an obsolete patent of theirs in 1853, from which they state that they granted a licence to Mr. Hodgson's father, in reality belongs to a much older patentee, whose rights have also expired. The question, however, at the present moment, is not who did or did not first propose to dry peat, and then compress it, instead of compressing it first and drying it afterwards, but who is really in possession of a method practical in all its details of cheaply drying that substance (which is economically by far the most important of the two operations), and afterwards compressing it. For the accomplishment of these objects means were proposed under patents taken out in 1849-50 by Green, in 1852 by Kingsford, and in 1853-4 by Messrs. Gwynne. But none of the plans so suggested were successful, and the subject remained in complete abeyance till the adoption, at a comparatively recent date, by Mr. Charles Hodgson, of the system of applying continuous pressure in a cylindrical tube, and his employment of the simple means of obtaining and drying the raw material witnessed by the members of the Institution of Mechanical Engineers during their visit to Ireland. We have noticed many efforts for the utilization of Irish peat during the last forty years. Perhaps no subject is more essentially connected with the development of the resources of Ireland, and at the same time of interest to the mechanical engineer. The matter is one of peculiar interest, from the great difficulties which have had to be overcome. We may safely say that in having brought the manufacture to a really practical issue, which, from our own knowledge, and from the experience of the President of the Irish Institution, we find to be the case. Mr. Hodgson has made a considerable stride beyond the points of difficulty at which previous inventors stopped short. The fuel, thousands of tons of which have been manufactured, and of which samples have long been in our possession, has been employed in Messrs. Guinness' and other breweries and manufactories, besides

Digitized by Google

being extensively used as household fuel in Ireland; and it would be hard to overrate the importance, in a national point of view, of the full development of such an industry.

PREVENTION OF COLLIERY EXPLOSIONS.

BRITAIN is pre-eminent for its colliery explosions; they occur at almost regular intervals with fearful loss of life and destitution to the families bereaved. The Davy and the Geordie lamps may lessen somewhat the frequency of their recurrence, but we are a long way from having done what we might have done, and must do, to prevent them. Though we are pre-eminent, we do not stand alone in these dreadful catastrophes. Germany also has her share, though a small one when compared with ours. There has just been a terrific explosion of firedamp at the colliery of Neu Iserlohn, near Bochum, in the centre of the Westphalian coal field. About 120 men were at work at the time in the pit; at the time of the last account received the greater part of them had been brought to bank, and, as might be expected, nearly all of them dead, and those that were not dead were frightfully injured. We do not give this as a piece of news, for all our readers will have seen a notice of it elsewhere; but we pass over these things now without paying much heed: they are so common. We wish to press it upon the scientific mechanician, as suggesting a problem to be solved—the prevention of such desolating explosions. Within the last few years these explosions have been even more frequent than usual, and that has somewhat awaked us to the necessity of trying to devise some means of prevention.

The whole problem resolves itself into simple ventilation. Several plans have been set forth, some good and some indifferent, but all of them expensive. Owners of collieries will not adopt expensive preventive measures, because they are not sure of their efficacy, and would rather wait till some less expensive experiment is suggested. We have seen one plan, that has not been published, which we think would be effective, and certainly would be comparatively inexpensive; but we will describe it, that our readers may form their own opinion about it. In applying this system of ventilation there is no need to sink new shafts; the existing shafts can be made to act as both up and down-cast shafts. We will take one gallery from the shaft up to the working face, and describe the application of the plan to that which, with slight modifications, according to circumstances, can be applied to the rest. Where these galleries are made only sufficiently wide for the convenience of working they would have to be widened, but that would be no detriment to the plan, as it would be easier to mine along the side of an existing gallery than to drift a new one. We will suppose the size of a gallery suited to the application of this plan to be about a yard and a-half wide. Let this gallery be divided into two passages, one a yard wide and the other half a yard, more or less—the wider passage to be applied to the traffic, and the narrower as an air or gas passage. In drifting this gallery the division between the two passages would have to be marked out and levelled, and a channel cut for the base plate of the partition. This base plate might be a board of two inches thick and six inches wide, and a convenient length would be about six feet. This would serve as a shoe for the partition, pieces of wood two inches square being nailed or screwed on to each side of the board to form a two-inch groove in the middle for the partition to slide into. On the boards, which may be placed to support the roof, a similar groove must be made, but only one side of it at first, till the boards of the partition are in their place.

The side pieces which form the groove on the base plate may be made to break joint with the plate, and so join the whole together. The boards to form the partition must be 2in. thick, and any width. There must be a half-inch groove down the centre of each edge about an inch deep, into this groove laths must be made to fit tightly, so as to make the partition air-tight when in position. This partition must be carried on as the working proceeds, and must be kept as near the working face as convenient. This air passage must be carried to the bottom of the shaft where the similar passages from all the galleries will meet, and thence proceed to the top of the shaft in one passage, at the mouth of which must be placed a fan to draw out the air or gas. It would be well if the galleries could be made with a slight descent towards the shaft, so that the choke-damp might flow down as water, and at the shaft a well or reservoir should be made to receive it, whence it could be drawn by a pump which, of course, must communicate with the reservoir by a pipe distinct from the fire-damp passage. The air or gas passages being constructed as the work proceeds, and the fan and pump being in motion, this would be the result. The air or gas passage would be continually exhausted, pure air would flow down the shaft and along the traffic passage up to the working face, and there turn round the end of the partition, and carry with it all the noxious gases, and thus keep the traffic passage and working face perfectly pure.

The miners would thus work in pure air, and might used naked lights, or the mine might be lighted with gas without fear of explosion. Every part of the ventilating apparatus being exceedingly simple it could not get out of order, with the exception of the engine at the top of the shaft. To prevent accident here, two complete engines and boilers might be kept to work on alternate weeks, so that one would always be in order. The 2in. boards for the partition or diaphragm would be the most expensive part of the material in an extensive mine; but then these partitions would serve as props also to support the top of the gallery. This system, it seems to us, would give perfect ventilation, and at a comparatively small cost, with simplicity of construction, and it would not be at all liable to get out of order. We offer it for the consideration of those who are conversant with the ventilation of mines.

REGISTERING ELECTRICAL THERMOMETER.

DEFINING the temperature of a body as the energy or force with which the heat within it, acts in transferring and communicating a portion of itself to another body, instruments employed for the accurate determination of that temperature are called thermometers. A distinction must be made between these instruments and those termed calorimeters, the latter being intended for ascertaining the actual quantity of heat imparted to, or abstracted from any substance. In one sense, every body is a thermometer, for since all known substances expand by heat and contract by cold, it is only necessary to provide means for measuring those expansions and contractions, and from the effect, the extent of the cause may be calculated. Very recently, Général Morin, whose name is well known in connection with scientific experiments and researches, has laid before "L'Académie des Sciences" an account of a thermometer designed for registering the variations in temperature of any given locality, or of the atmosphere, at regular intervals of time, which may be varied to suit the requirements of the case. It consists of an electro-magnetic apparatus, somewhat similar to that of M. Becquerel, and is composed of thirty rods of German silver and iron, fixed separately and parallel to one another in grooves sunk in the surface of a wooden cylinder having a diameter of a couple of inches. The ends of these rods project beyond the edge of the cylinder, and are soldered with tin, each to its alternate neighbour, thus constituting a pile of fifteen elements. According to the intensity desired to be given to the current which is set up, so soon as the opposite extremities of the rods are at different temperatures, so is their number increased or diminished. This current is caused to traverse the two coils of an ordinary multiplier, which carries a magnetized needle suspended by a silken thread, and the normal position of which is in the plane of the magnetic meridian. The axis of the needle is prolonged below and carries at its lower extremity another needle of copper very delicately balanced, and intended to record the deviations of the one above it. To effect this result, immediately under the copper needle a horizontal disc is placed eight inches in diameter, and furnished with a sheet of paper. The disc is mounted upon a vertical axis to which is imparted a regular movement of rotation, through the agency of clockwork. In addition to the rotatory motion, one in a vertical direction is also communicated to the disc carrying the sheet of paper, at intervals of every quarter of an hour. At these periods an ascending and descending motion is given to the disc, the first being accomplished by the descent of a balance weight which is raised by the second motion, both of which are effected by the spring of a special drum attached to the chronometric motor.

The action of the little apparatus is very simple. Every quarter of an hour the disc, together with the sheet of paper, rises towards the recording needle, which punctures it, thereby indicating at that instant the position of the magnetized needle above it. Upon the descent of the disc, the point is disengaged from the paper and the needles restored to a continuance of the oscillations from which they were momentarily suspended. The sheet of paper furnishes, consequently, an accurate register of the periodical deviations of the magnetized needle, and by connecting the different points traced upon its surface, a curve can be readily obtained which will indicate the relative march of the temperatures at the opposite extremities of the electrical thermometer. If the instrument be graduated by marking upon the paper the normal position of the needles, or that in which there is no current established, the corresponding curve will be a circle, indicating the zero of the deviations, or the difference in temperature at the extremities of the rods. When one of these extremities is maintained at a constant temperature—that of melting ice, for instance—the deviation of the needle will indicate the temperature of the medium into which the other is plunged. Similarly to all delicate and sensible scientific instruments, the electrical thermometer must be sheltered, by means of a double case, from all external influences which might tend to vitiate the accuracy of its results. Due precautions having been taken to insure the fulfilment of these conditions during an experiment, it will be found that, when the temperatures of the opposite extremities vary by regular degrees, the curve formed by joining the points traced upon the paper will present a uniform curvature resembling that represented in fig. 1. If, on the contrary, the opposite extremities of the thermometer be exposed to sudden and frequent changes of temperature, the corresponding curve will present the appearance shown in fig. 2, and be broken into a number of abrupt and irregular sinuosities. From the ordinates of a series of curves the general law of the variation of the temperatures may be deduced. Before using any instrument of the character in question, it is indispensable to ascertain its "index error," to employ a term well known to optical and mathematical instrument makers, and to make an allowance for it in all succeeding operations. This was effected by Général Morin, by direct experiment which we shall not pause to describe, as it in no manner affects the utility of the apparatus. The

Digitized by Google

original object of the inventor in designing the electrical thermometer was to obtain by its means the difference of the temperatures inside and outside a ventilating flue, at regular periods during the day and night. This difference, if the ventilation of an apartment were perfect, would be constant, since the movement of the air would be also constant. It is easy to perceive that, supposing one of those instruments were placed in a hospital, a simple inspection of the curves traced upon the paper would at once afford all the information necessary respecting the condition of the ventilation. The sensibility of the apparatus can be augmented to almost any

FIG. 1.

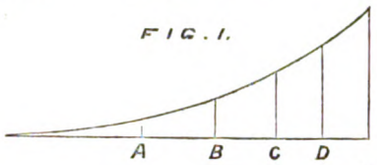

FIG. 2.

extent, either by employing needles of a very high degree of sensibility, or by multiplying the elements of the pile, but this feature is not carried to a great excess, since many practical disadvantages attend the use of scientific instruments, which are too readily susceptible of the effects they are intended to record. In the hands of skilful experimenters, the electrical thermometer is calculated to be of great importance in ascertaining and registering physical facts, more especially those relating to meteorology. Général Morin states that he borrowed the idea of obtaining a record of the deviations of the magnetized needle in the manner effected, from Mr. David Napier, who, as some of our readers may recollect, exhibited in the London Exhibition of 1851 a compass for the purpose of registering the progress of a vessel by means somewhat similar. A model was purchased by the French authorities, and placed in the collections of the Conservatoire, where it is at the present time.

RAILWAY ROLLING STOCK OF THE UNITED KINGDOM.

IN the course of last year there was doubtless a considerable increase in the rolling stock of the railways in the United Kingdom, but it was less, it may be supposed, than the increase in 1866, when the projects for new lines reached the last culmination. The almost total cessation in the construction of new lines, and the pressing necessity for economy in expenditure for working expenses and other departments, renders it extremely improbable that there will be any considerable increase in the number of engines and other rolling stock in the current year, in addition to renewals and making good for tear and wear. The returns of the stock at December 31, 1866, which are just published, represent substantially what it is likely to be for some years to come, with slight increase. At that date the rolling stock of the railway companies and of the proprietors of railways in Great Britain and Ireland, was as follows:—Locomotives, 8,125; passenger carriages, 19,228; other vehicles attached to passenger trains, such as fourgons, carriage trucks, horse boxes, post-office vans, break vans, &c., 7,276; waggons and trucks for the conveyance of live stock, minerals, and general merchandize, 236,791; other carriages and waggons, 6,156; total, 277,576. The locomotives are 711 more numerous than they were in the previous year; 1,654 passenger train carriages have been added; 16,540 waggons and trucks; or a total addition of 18,905 engines and vehicles. It is difficult to realize the enormous stock represented by these figures. If it were possible to make up the whole into one train, placed buffer to buffer, it would be about 1,000 miles long, and would reach for hundreds of miles more than the distance between Land's End and John O'Groat's House. It would be headed by about 50 miles of locomotives and tenders, about 100 miles of passenger carriages, and 850 miles of mineral, live stock, goods and miscellaneous waggons, trucks, and vans.

The amount expended upon locomotive power during the year was £5,253,843, or 27·93 per cent of the working expenditure, being an increase of £541,581 as compared with the previous year. The expenditure for maintenance of way and works was £3,466,668, or 18·43 per cent. of the working expenditure; for repairs and renewals of carriages and waggons, £1,539,332 was expended, or 8·18 per cent. The total expenditure under all heads was 49 per cent., or an increase of 1 per cent. as compared with the previous year. The working expenditure of the Irish railways amounted to 57 per cent. of the total receipts, or an increase of 10 per cent. as compared with 1864. There were 13,854 miles open at the end of 1866, or an increase of 565 miles as compared with the previous year. There were 274,293,668 passengers carried exclusive of season ticket holders, to whom there were 110,227 tickets issued, whose journeys would add at least 30,000,000 to the number of passengers. There were 3,741,086 passenger and 2,305,133 goods trains run; their total running was 6,046,219 miles, or 489,512 miles more than in the previous year. The mere increase is equal to above twenty times round the earth, and the total mileage run by trains above 250 times round the globe. The total receipts from all sources amounted to £38,164,354, being an increase of £2,274,241 as compared with the preceding year.

THE PROPOSED AMERICAN NAVAL BOARD.

THE Americans are seeking to establish a Naval Board of Survey, and this is not a new matter of consideration with our friends across the Atlantic. The question was mooted during the American war, but the general excitement of the times forbade its serious consideration, and the proposed measure fell through. As far back as 1842, the organization of the navy department was proved to be defective, and a remedy was sought by apportioning out the work among several bureaus. This, with the "old Navy Commissioners," as they were styled, would have assimilated that department to the French system, but the egregious blunder was committed of suppressing the Navy Board, thus creating a hiatus—a break in the connection—and completely destroying the system. It is the object of a bill, which has been introduced into Congress by Mr. Nye, to correct the mistake then made, and to furnish the centralizing power necessary to the harmonious working of the several bureaus. The Secretary himself, were he a professional man, would supply that power; but he is, and ever must be—with the Americans—a civilian and a statesman. Those of his duties, therefore, which are strictly professional, should devolve upon officers of rank and experience, who have ability to administer to the affairs of the navy. This is, in effect, what Mr. Nye's bill proposes to secure, and that the plan is founded in a wise, far-seeing policy, the practice of the French for the past forty years, with its excellent results, and the overwhelming testimony of English writers on the subject, fully prove. But Mr. Isherwood, Chief of the Bureau of Steam Engineering, strongly protests against supervision and interference. On the other hand, the American public appears determined to have some controlling influence brought to bear upon the actions of a chief who, by all accounts, has squandered public money, and has not always shown fair play to men in civil life who have been brought into competition with him. On this head we have only to refer our readers to the celebrated trials of the "Winooski" and the "Algonquin" which took place about two years since. Here two vessels were tied by the stern to the wharf and set to paddle away as hard as they could. A remarkable trial, truly, but remarkable only for its absurdity. In a few words, it would seem that the efficiency of the Chief is called into question, and there are ample reasons for this. A rigid scrutiny is demanded over the several departments, and this the Naval Board proposes to supply. The matter is now well in hand, and we advise Mr. Isherwood to submit to it with a good grace. That he does not, would appear from a humorous extract from an American contemporary, which we reproduce on another page. Mr. Isherwood's blunders are not unknown in England, for blunders are things which travel quicker than fame, which they often outlive. Let us ascribe these to an overworked mind, and counsel Mr. Isherwood to welcome a change which will relieve him of many anxieties, in that it will reduce his responsibilities.

RESTORATION OF THE CRYSTAL PALACE.

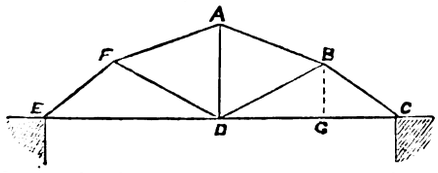
NO one who has visited the Crystal Palace can help expressing feelings of real regret, at witnessing the effects of the lamentable catastrophe that a short time ago befel that national rendezvous of amusement and instruction. It is not too much to assert that, in spite of age and experience, those who explored its almost innumerable attractions, seemed to renew the faith of their childhood. The "Tales of the Genii," the fairy fables of "The Arabian Nights," and the beautiful romantic legends of Washington Irving, were displayed in full realization, and the diversities of centuries, and the progress of epochs, might be discerned in the delicate symmetry of the "Halls of the Alhambra" and the barbaric majesty of "The Egyptian Court," Our readers will be happy in the prospect that these lately demolished portions of the Palace are in course of restoration. Finding it at present impossible to complete within a reasonable time the whole of that portion of the building and its contents injured by the fire, the Company have adopted a very wise course of action. They have determined upon finishing about one-third of the length of the part destroyed, and have restored the end of the building at that point, so that to the visitor the interior would present not the slightest sign of having been otherwise than it appears to the view. We are glad to perceive that this partial restoration includes the "Alhambra Court," which, without the slightest detriment to the beauties of its neighbours, may be pronounced as, "par excellence," the gem of that particular class of attractions. By adopting this judicious arrangement, the farther restoration of the length outside the present north end can be carried on without in any manner interfering with the remainder of the building. The interior of the restored portion is not yet completed so far as the courts and ornaments are concerned, but the whole of the girders, framework, and glass-work is finished, and in a few days the screen which has interposed between the restorations and the rest of the building will be removed. Outside, to the accurate observer, there will, of course, be a difference in the distance of each end from the centre arch, but to the casual visitor this discrepancy will not be apparent, and it will be very difficult to detect it in the interior. To those who are well acquainted with the structure, the vista, look-

Digitized by Google

ing from the gallery at the south end, appears slightly different from its original aspect. The building seems somewhat "raccourci;" but we are perhaps speaking too critically. A fountain precisely similar to that placed opposite the Egyptian Court is fixed in the restored part, and only requires the water to be let in to be complete. Before the summer season commences, the proposed restorations will be accomplished, and, with the exception of the temporary unavoidable omissions, the Palace will assume that appearance which it presented previously to its partial destruction.

STRAINS IN ROOFS.

IN order to find the strains in such a form of roof as exhibited in the annexed diagram, we have to consider, first, in what manner the load is distributed. If it be uniformly distributed over the ribs or rafters, then we know that the resultants will pass through the middle of each rib. Taking the sum of the resultants, we get the supporting forces at C and E, each of which forces will



be equal to half the load. Now, in order to find the stress upon the rib B C, draw B G perpendicular to E C (the horizontal tie rod), then if the line B G be supposed to represent the vertical supporting force at C, which is equal to half the load, G C will be the horizontal stress on the tie rod E C, and B C the stress on the rib B C. Again, by similar reasoning, we can determine the stress on the rib A B; in this case, however, the vertical force is equal to the load on that rib. We have thus two horizontal stresses at B, viz., that due to the load on the rib B C, and that of the load on A B. If these thrusts balance each other, that on B C acting inwards at B, whilst that on A B acts outwards at that point, then the bracing is not required, but if either be the greater, the braces B D, F D, and A D, must be introduced to restore equilibrium. If the resultant horizontal thrust at B acts outwards, the brace B D will act as a tie; if inwards, as a strut; the stress upon A D will be of the opposite kind in each case. This is evident if we consider the condition of the roof opening outwards at F and B. The top at A would tend to settle down. The outward action being transferred to the braces B D and F D, is transmitted by them to the bar A D in the form of an upward thrust, which, reacting on the upper part at A, counteracts the downward tendency already mentioned. If the horizontal thrust be inwards at F and B, the opposite effects will ensue, but equilibrium will be again restored, the vertical piece A D in this case acting as a tie by holding down the roof at A.

The amount of the straining action on A D may be determined by constructing a parallelogram whose adjacent sides represent in magnitude and direction the stresses on the braces; the diagonal of this parallelogram will represent the stress required. The amount of the forces acting upon the braces B D and F D is found by constructing a right-angled parallelogram, the diagonal of which represents in magnitude and direction the resultant horizontal thrust at B, then the side sloping in the direction B D will represent the stress on the brace B D. W. J. M.

PHOTOGRAPHY.

NEW DRY PROCESSES—A NEW PHOTOGRAPHIC PERIODICAL—THE TOTAL ECLIPSE OF THE SUN —DIFFUSION OF FOCUS.

MR. M. CAREY LEA, of Philadelphia, has recently been making experiments to simplify the present dry processes. At present, Sayce's collodio-bromide process is the simplest of all. He adds nitrate of silver, very finely powdered, to a collodion containing bromide only, and the addition is made in such proportions that the whole of the bromide shall not be decomposed by the added salt. A fine precipitate of bromide of silver is thus held in suspension in the viscous collodion, and plates are covered with the solution in the ordinary way, then immersed in water for a few minutes, and afterwards dipped into a solution of tannin and dried. The trouble of preparing these plates is less than in any other dry process, the morphia process excepted, but many who have tried the latter find that the plates will not keep.

In searching for an improvement upon Sayce's process, Mr. M. Carey Lea acted upon the principle of adding the organic preservative to the collodion, so that after coating a plate it should only have to be washed in water, and dried, to be ready for use, no after-bath of tannin or other organic substance being necessary. The collodion was made in the following proportions:—Alcohol, ½oz.; ether, ½oz.; bromide of cadmium, 4gr.; bromide of ammonium, 3gr.; camphorated tincture of soap, 5 minims; and pyroxyline, 4 or 5 gr. Before use, 40gr. of very finely-powdered nitrate of silver were added in the dark to every 3oz. of the collodion, shaken up, and filtered. The film having been allowed a little time to set, was then immersed in water for a few minutes, taken out, dried, and the plate was ready for use.

It will be noticed that the organic matter in the above collodion consists of the camphorated tincture of soap, which would cause the formation of a little oleate of silver. The camphorated tincture of soap of the American pharmacopœia consists of:—Soap (in shavings), 2oz.; camphor, 1oz.; oil of rosemary, 2 drachms; alcohol (sp. gr. ·835), 16 fluid ounces. As a matter of scientific curiosity, but not as a good practical working process, Mr. Lea announces that to a collodion like the above, but without the tincture of soap, the following additions may be made just before use:—Gallic acid (60-gr. solution in alcohol), 24 drops; glycerine, 20 drops. The plate is simply coated with this collodion, and without further treatment exposed in the camera. After exposure, the slide is put aside for a few hours, and then, after being opened, a fully-developed picture will be found upon the plate. The pictures he has thus obtained are doubtless not of good quality, for he considers the process not to be practically useful.

The Government of India is now making great preparations to photograph the total eclipse of the sun this year, which will be visible in that country, and the time of almost total obscuration will be five minutes, so as to give plenty of time to take five or six negatives. The telescope is now in course of construction by Mr. Browning, and the elevation of its polar axis is very small, because it will have to be used so near to the equator. The instrument strongly resembles the one belonging to Mr. Warren De La Rue, at Cranford Observatory. It is a reflecting telescope, on the Newtonian principle, the image of the sun being thrown out at the side of the tube by a second reflector of speculum metal.

In the early days of photography, a great outcry arose for lenses which would give pictures of the utmost sharpness, showing, if possible, every hair in the head of a sitter. Of late, this qualification has not been so much desired, especially when the lens is intended to take large heads in portraits, because then the nose, and other projecting parts of the face, may be taken with the utmost sharpness, every pimple standing out in the most unpleasant manner, while the back of the head and part of the side of the face would be hazy and out of focus. Many methods of getting rid of this excessive sharpness in large heads have been devised. Mr. Robert Snell, and the late M. Claudet, independently of each other, suggested the plan of moving the lens during the exposure, so as to bring all the planes of the face successively into focus, giving moderate definition everywhere and minute definition nowhere. Mr. Dallmeyer manufactured a lens which gives diffusion of focus, without being moved during exposure, and it was made on a plan first published by Mr. John Traill Taylor. The latter gentleman also suggested a plan of getting diffusion of focus with a sharp lens, by stretching a piece of catgut from the camera to the floor, and playing upon it with a fiddlestick during exposure, whereby the vibrations would soften the sharp lines of the picture, and the music produced would bring an expression of delight into the face of the sitter. Another suggestion was, that the boards of the room should be loosened, and during exposure the operator should execute a hornpipe or Highland fling alongside the camera, whereby such motion would be communicated to the latter instrument that it could not take a sharp picture.

THE ADJUSTABLE BELGRAVIA SEWING MACHINE.

AMONGST the numerous sewing machines now before the public are many which possess undoubted special merits, but certainly the most perfect and complete of its kind is that known as the adjustable Belgravia machine. This apparatus consists, primarily, of a Wheeler and Wilson's machine, upon which some very important improvements have been engrafted by Mr. John Mabson, of Newcastle-on-Tyne. These improvements are no less than seventeen in number, and include various appliances for doing different classes of work. To enumerate and describe all these would not be to our present purpose; we may, however, refer to the principal among them. There is an adjustable cloth presser, a cloth plate, and a belt tightener, which may be classed amongst the improvements in the machine itself, whilst a self-acting creaser, and an embroiderer, may be considered, with others, as extra appliances which can be had separately from the machine. With regard to the capabilities of the machine, we may observe that it will make the Wheeler and Wilson, or lock-stitch, the Wilcox and Gibbs' stitch, the Grove and Baker stitch, the pearl stitch, the cable stitch, and, finally, the Belgravia embroidery stitch, which is made on the right or upper side of the material—a thing never before accomplished. The Belgravia stitch constitutes a very important improvement in this machine, and is made by a most ingenious mechanical arrangement. There are a pair of claws or thread guides resting on the presser foot, and which open at one stitch and close at the next. By this means the embroidery threads are crossed, and at each crossing are secured to the fabric, to be ornamented by the machine working the ordinary lock-stitch. Various thicknesses of the embroidery material may be used, and the pattern may be carried to any width. The most elaborate and intricate designs can be correctly followed, the pattern being distinctly seen through the crystal presser. We have seen a variety of articles worked by this machine; amongst others, is a striking likeness of the Queen stitched in outline with the lock-stitch, and enclosed in a border of rich embroidery. There were other examples of the most elaborate embroidery, done with threads of various colours; there were also muslin aprons which were tucked, creased, and embroidered at one operation. The ordinary Wheeler and Wilson machine, of which the patent has expired, obtained a gold medal last year at the Paris Exhibition. As this machine forms the basis of the Belgravia machine, it is a pity that Mr. Mabson was not ready with his improvements so as to have exhibited, for it is but reasonable to infer that the great advance he has made would have secured him the medal. As it is, however, we are glad to learn that at the Liverpool and Manchester Centenary Agricultural Show, held last year, Mr. Mabson was deservedly awarded the silver medal for "valuable improvements." His mechanical skill has enabled him to produce a machine which commands a wide sphere of usefulness, its work ranging from the simplest stitching to the most elaborate and finished embroidery. Viewed simply as a piece of mechanism, it is a singularly perfect and unique production, whilst its general utility cannot fail to make it a favourite with the public.

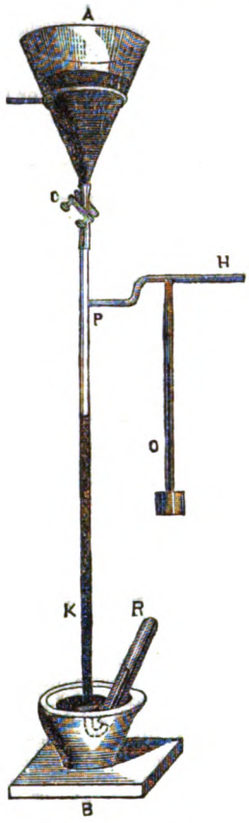
THE SPRENGEL AIR-PUMP.

AN air pump designed three years ago by Dr. Hermann Sprengel, without attracting much attention at the time, has lately come much into use by scientific men, and has several times called forth the approbation of the Royal Society. It may be readily constructed by anybody in its primitive form, and if philosophical instrument makers would but adopt the principle, they might turn out a much better and cheaper instrument than the present double-barrelled pumps. In its simplest form the pump consists of a funnel A, with a glass tube C K below. The joint C, between the funnel and the tube, is made of well-fitting black vulcanized india-rubber tubing, sold under the name of French tubing. This is free from metallic



oxides which render the tubing porous; it is necessary that the joints should be bound with copper wire, and afterwards coated with gutta-percha applied in a melted state. Everything depends upon a good joint. There is also a clamp at C, which closes the tube. Now when the funnel A is filled with mercury, and the metal is allowed to flow downward in drops through the tube C K, which is two and a-half millimetres in diameter, each drop of mercury acts as a piston, and drives some of the air out of the tube before it. The lower part of the tube may be turned up in a pneumatic trough or other vessel B, full of mercury, where the air or gas driven out may be collected. P H is a glass tube branching out from the main tube, and to this one a bottle or any other vessel to be exhausted may be joined. O is a barometer to show the extent of the vacuum produced, and R is a vessel collecting the air or gases forced out by the falling mercury. So efficacious is the action of this simple pump that the mercury in O will rise to the same height as in a barometer not connected with the pump, which therefore produces a perfect Torricellian vacuum. The Sprengel pump is, therefore, infinitely superior to the ordinary double-barrelled air pump.

There is no reason why pumps on this principle should not be introduced into the market, with ordinary plates and receivers conjoined therewith. The glass portions can be supported and protected by woodwork by simply sinking the tube and its branches in grooves, and screwing a second board over the movable ports. The vessel at the bottom which collects the mercury should have a tap to carry off all which rises above the proper level, so that the surplus may be employed to replenish the funnel. Thus may a very superior and cheap instrument come into common use.

The vacuum produced is so perfect that, when tubes on Geissler's principle are exhausted by the pump, they show no red bands on the spectroscope, not a single trace of nitrogen. A blue steel flame is given, due, perhaps to vapour of mercury. Faraday believed that electricity was but a peculiar condition of common matter, and that it, therefore, could not exist where matter was not present. Yet no vacuum has yet been produced where the discharge from a large coil machine will not pass, though Mr. Gassiott and others have made vacuum tubes which proved good insulators to a considerable extent. The best vacuum obtainable from the Sprengel pump gives the steel-blue flame.

MANUFACTURE OF MALLEABLE IRON.

MR. J. HARGREAVES, of Appleton Widnes, Warrington, has been some time investigating the causes of loss of metal when malleable iron is made from cast iron, with the object of reducing that loss as much as possible. The loss of weight caused by the abstraction of carbon, silicium, sulphur, &c., is of course unavoidable, so far as the elimination of those elements themselves are concerned. But when silicium is present, whether in combination with the iron, or in the form of sand adhering to the pig, the formation of oxide of iron is required to effect its separation, in the form of tap cinder, or basic silicate of iron, and this oxide is obtained at the expense of the metal. The sand which adheres to the pig thus causes a loss of from three to seven times its own weight of iron. Not only is there this loss caused by oxidization, but the time, labour, and fuel required to effect it is thrown away. It is, therefore, desirable that the presence of silicium, whether in the form of sand or otherwise, should be avoided To prevent the loss of metal from this cause (generally amounting from 3 to 6 per cent.), the iron is run from the blast furnace into beds of granulated or powdered iron ore. By this, not only is the loss of metal reduced, but the time, labour, and fuel required to puddle it are also appreciably diminished, the iron is somewhat improved, and the production of tap cinder diminished. This improvement has been patented. Makers of malleable iron will readily appreciate the improvement. To ironfounders it is also of importance, as they avoid the loss of weight and depreciation of quality consequent on the presence of sand, and a smaller amount of flux is required in the cupola. We understand that there is no expense required to put it in operation, except the difference between the cost of sand and small iron ore.

SOCIETY OF ENGINEERS.

(Concluded from page 67).

THERE is one subject, in connection with the construction of the sewers themselves which is of such vital importance that mention of it must not be omitted, and that is the subject of ventilation. It appears to have been to a very great extent ignored in all the early sewer works of this country, and it can never have occurred to the designers of those early sewer works that the volume of water poured into a sewer always displaces an equal amount of the mephitic air of the sewers. It may be taken for certain that deleterious gases are liberated in every system of sewers, from the very moment fæcal or other decomposing matters are admitted into them, to the time the sewage is utilized upon the land, or entirely dissipated by being poured into the sea. The very fluctuation of the flow of sewage through a sewer will give those gases a force, in an unventilated system of sewers, that will enable them to pass through any trap, and so into our habitations. On the other hand, the fluctuation in the flow of sewage is a valuable aid to a system of properly ventilated sewers. The happiest results have attended the introduction of a system of sewer-ventilation in Croydon: the average improved rate of mortality in Croydon has been reduced two per thousand by it; and in Liverpool, which has been proverbially an unhealthy place, the mortality has been reduced from 42 to 30 per thousand, chiefly by the ventilation of the sewers. With regard to the gases escaping from the ventilators, the principle of oxidizing them by charcoal, as recommended by Dr. Stenhouse, is easy of application, and has proved very successful in its results. There are other modes of disinfecting or dissipating the sewer gases that may be adopted in particular cases; but as the method to be adopted depends upon local conditions, no general rule can be laid down for the guidance of the engineer in the matter, and he must, therefore, in every case, adapt general principles to local circumstances.

Sewers remove by the aid of water those matters that are so pernicious to our health and life; and, therefore, the question of water supply, as one of the great aids to sanitary success, demands the earnest consideration of the members of our profession. The various questions concerning the provision of water for our fast increasing populations are of great moment, and the matters relating to the purity and the modes of preserving or effecting the purification of our water supplies are also of great importance. Men in all ages and countries have given a great amount of attention to the means of procuring good and abundant supplies of water. In bygone ages, works of great extent have been executed in order to convey life-giving streams from great distances to the crowded cities of their times, and many of those works have been of so colossal and durable a character as to outlive the very cities they were intended to supply. In our own day we find pressing necessity for water so great, that schemes are proposed of a magnitude surpassing those that have been before executed in any age or country. We have the scheme of Mr. Bateman to bring the water of the upper tributaries of the Severn from the Welsh hills, by a conduit, 183 miles long, for the supply of water to the three million inhabitants of London, and the inhabitants of the towns on the line of the aqueduct. By this scheme it is proposed to give a constant supply of water at sufficient pressure for all purposes, the lowest reservoir in the scheme having an elevation of 450 feet above Trinity high-water mark. It is ultimately intended to bring 200 million gallons of water per day into London, the present supply being about 100 million gallons per day; but at first it is only intended to furnish 120 million gallons per day, and it is estimated that the work will cost £8,600,000. We have also the scheme of Messrs. Hemans and Hassard, of tapping the lakes of Cumberland and Westmoreland, and impounding the water of that very wet locality, carrying it by a conduit 240 miles in length. The minimum elevation of the source of supply would differ but slightly from that of Mr. Bateman. The cost of this project to convey 250 million gallons of water per day to London is estimated at £12,200,000; if 200 million gallons only were required, the estimated cost is £11,200,000.

Then we have the scheme of Mr. Remington for collecting the waters of the Dove, the Wye, and the Derwent, from the hills of Staffordshire and Derbyshire, and conveying them to London, by an aqueduct 138 miles in length, and at sufficient elevation to distribute the water for all purposes. The quantity of water proposed to be supplied by this scheme is 83 million gallons per day, and the cost of the works are estimated at £5,000,000. We have also the scheme of Mr. Dale for supplying the populous towns of Lancashire and Yorkshire with 131 million gallons of water per day, to be taken from the lakes of Cumberland and Westmoreland; and it is estimated that this scheme will cost about £9,000,000. Other schemes have been produced for improving the modes of increasing and perfecting the local supplies of water, whose authors think that, by proper means, we may enjoy in their virgin purity those supplies of water that nature has directly placed at our disposal. Vast sums of money have of late been spent in establishing or extending systems of waterworks in our populous cities and towns, and the experience that has generally been gained leads us to draw some general conclusions applicable to all works.

Water supplies should be abundant and pure. The average quantity of water supplied to the population of 120 towns of the country is 25 gallons per head per day; in some of those towns the supply equals 50 gallons and upwards per head per day, and in others it is as low as 10 gallons per head per day. In studying matters relating to water supply, the purity of the supply is of paramount importance; the results of using impure water are generally more speedy and certain than those arising from impure air, as the poisonous matter taken into the stomach passes at once, by the process of venous absorption, into the system. Year by year is becomes more difficult to preserve the purity of our supplies of water. The greater the attention paid to the cultivation and manuring of land, and the continual increase of our population, tend materially to destroy the purity of our water supplies. It is an axiom, in seeking for water, that the purity of water and fertility of soil are never to be found together

The supply of water should be constant, and should be distributed at such an elevation as to command the highest houses. Such a supply is invaluable, and, in addition to the results to be gained in a sanitary point of view, the advantage of having water always at command for the purposes of extinguising fires, watering streets, flushing sewers, and dispensing with the drudgery and labour of carrying water, are very great. I cannot conclude my remarks on water supply without referring to the failures of reservoir dams, which unfortunately have of late been so common. The

Digitized by Google

thrilling interest taken in these failures, due to the calamitous results arising from them, will, it is to be hoped, lead, in all future works, to more care and attention being paid to the construction of the work itself and to its position, with a view to secure immunity from such sad catastrophes. That sanitary works have answered the purpose for which they were intended, and that sewerage and water-works have been the means of accomplishing this end, is abundantly shown by the results, whereby the lives of thousands of our teeming populations have been saved, and much misery and suffering prevented, and, at the same time, the social and moral habits of the people raised by the means that have been adopted.

In concluding my address, it may be remarked that modern engineering had its birthplace in this country, and we trust that it will ever find its home in it. We cannot but feel justly proud of the great strides that our profession has made, and is still making, and of the great benefits it has conferred on the civilized world. A century and a half ago there were no modern engineering works of note—no canals, railways, harbours, or roads worthy of the name; but at the present day works of great utility and magnificence have been constructed, and there is no obstacle so great that it cannot be surmounted by the diligence and skill of our profession. If mountains obstruct our progress we tunnel them; if a valley or stream intervene between us and the object of our ambition, we bridge it. We set up barriers to curb the fury of the ocean, and we multiply the means of international communication, thus bringing man and his follow-man into closer communication and relationship. We make use of the great power of electric currents so that we are able to flash our thoughts from land to land with the instantaneous velocity of lightning. We perfect the machinery used in the manufactures of this country, and multiply the conveniencies and luxuries of civilized life, and bring them within the reach of all classes of our communities. We tap the living streams of water, and bring home the life-giving element to quench the thirst of our communities. We remove, in an expeditious and inoffensive manner, from the midst of our populations those matters thrown off by nature and destructive to life, and thus set a bound to the tide of disease and death. We bring up from the buried stores of nature materials that are used for the comfort of man, or are fabricated into countless forms, and without which we should be unable to carry out those great works which mark the progress of modern engineering, and stamp the age in which they are executed with their character. The great progress made by our profession shows that its members have been equal in ability to the varied tasks they have had to perform; but let us not trust to our prestige, but endeavour to open up new fields for labour that may improve our manufactures and facilitate our commerce, and so defy legitimate competition.

In the sanitary works of the country, in agricultural engineering, in the gigantic schemes for ship canals proposed in distant parts of our own empire, and likewise works of like magnitude proposed in other countries by our own countrymen, and in which English capital would be expended, we may find an outlet for our talent and employment for our industrial classes. We cannot be unmindful that our profession imposes upon us an important trust; we have received it in its full vigour from the hands of those who have gone before us, and it is now our privilege to extend its usefulness, and hereafter to hand it down to posterity, not only unimpaired, but improved and perfected. As our profession is dependent for advancement upon many branches of art and science needing the strength and skill of the mechanic, the scientific knowledge and attainments of the philospher, and as it is not the knowledge of a single individual, but the accumulated knowledge of individuals and ages that makes up the whole profession of an engineer, this fully demonstrates the necessity of individual members of our profession making themselves conversant with the works and labours of others, and, by promoting an interchange of thought and idea, adding much to the general store of information which will not only advance our profession, but promote the true interests of the individual member.

It is by the aid of societies like this that we are enabled to accomplish that good for our profession we must each and all earnestly desire. I am right in saying that this Society has made greater progress, judging from the number of its members and the variety of the papers that have been brought before it, than any other engineering society during the period it has been established. The benefits of the Society are ours to enjoy, ours to preserve, and ours to transmit; then let us each individually strive to advance its interests, remembering that in promoting those interests we are truly advancing our own best interests. Let us strive to sink all jealousies, remembering that the field is extensive enough for the operations of various engineering societies and individual members of our profession; let us have no rivalries, except that rivalry of vieing with each other to promote the true interests and advancement of our profession.

HAVRE INTERNATIONAL MARITIME EXHIBITION.

WE have occasionally referred to the progress of the above project, and we now give the programme.

The exhibition will be open from the 1st of June next to the 31st of October. The exhibition is organized under the auspices of the Municipal Administration of Havre and of a general Consultative Commission. The programme of the exhibition includes forty-three classes, divided into the five following groups:—Navigation, goods, fishing, aquiculture, complemental classes.

1. Navigation.—1st class, sailing vessels (models and plans). 2nd, steam vessels, ditto. 3rd, wood-built vessels and composite (wood and iron). 4th, iron-built vessels. 5th, boats of all descriptions. 6th, masting. 7th, rigging. 8th, sails. 9th, materials for fitting out ships. 10th, preservation of ships. 11, furniture for vessels, steamers, yachts, &c. 12th, ship stores. 13th, sailors' outfit and chest. 14th, instruments for navigation, steerage, lighthouses, and signals. 15th, hygiene, ships' medicine chests, and surgery. 16th, apparatus for loading, stowing, unloading, and transhipping. 17th, life-boats, and other contrivances to save life and property; swimming apparatus; various objects for the use of bathers. 18th, paddle propell rs. 19th, screw propellers. 20th, engines, impellers. 21st, steam boilers and generators, fuel. 22nd, various parts of machinery belonging to marine engines and accessories. 23rd, various works relating to ports; repairing ships.

2. Goods.—24th class, textiles: cotton, flax, hemp, &c., wools, horsehair. 25th, colonial goods for consumption; home produce (similar). 26th, corn, alimentary flours, fruits, and seeds. 27th, dyeing and chemical produce. 28th, greasy and oily substances. 29th, woods wrought or unwrought. 30th, all kinds of metals. 31st, different sorts of goods and produce of industry for importation or exportation. 32nd, instruments and apparatus applied by trade to establish the quality or discover the adulteration of goods. 33rd, packing: produce used for manufacturing objects necessary to pack up goods.

3. Fishing.—34th class, whale fishing, &c. 35th, cod fishing, &c. 36th, coast fishing. 37th, river fishing and pond fishing. 38th, speciality of tackle and instruments used in fishing; bait, salt, preparation of fish; models of establishments for preparing fish; fishermen and sailors' outfit and clothing.

4. Aquiculture.—39th class, fresh and salt water aquaria.

5. Complemental Classes.—40th class, art annex, special naval art, art properly so called. 41st, writings and books, maps and plans. 42nd, competition and experiments. 43rd, nautical sports; representations, the plan and action of which will be taken from historical events or fabulous and legendary subjects.

A Maritime and International Congress will take place during the time of the exhibition. The exhibition will be held in closed galleries, which were begun in the month of July, 1867, on the grounds situated by the sea-shore, opposite the roadstead on the Boulevard Impérial and the Boulevard François I. These grounds are granted by Government. It contains, besides the galleries, an enclosure in the open air; a floating annex will receive special exhibitions. The whole surface of the exhibition is about five hectares, or twelve acres and two roods English measure, not including the annex above mentioned. Objects admitted will be exhibited under the name of the inventor, builder, manufacturer, or author, &c., and generally of the producer or the manufacturer. They may also be exhibited under the name of the shipowner, merchant, holder, collector, tradesmen, or the consignee.

Exhibitors will have the privilege of selling in the enclosure of the exhibition, commodities manufactured on the spot. They will have also in special galleries, for this purpose, the right of letting customers taste their produce and retailing goods similar to those exhibited. Non-exhibitors will not have this right. The rewards adjudged to exhibitors, on the decision of the International Jury, will consist of pecuniary gifts and objects of art, gold and silver medals and honourable mentions; there will be several great prizes amongst the rewards. The jury will begin their operations as soon as the exhibition opens. The rewards will be delivered at a grand assembly of the general commission on Sunday, 26th of August, 1868. A moderate charge is made to exhibitors on account of the expenses incurred by the erection of the building, and for watching, insuring, and keeping the same in order. Goods and produce will be received upon the premises of the exhibition from the 1st of March next until the 1st of May. Demands for space will be received up to the 15th of February only, and applications for forms should be made to M. Alf. de Lavigerie, Special Commissioner for England, 40, Great Titchfield-street, Oxford-street.

[We may add that the Commission of the Exhibition has just received from the Minister of Foreign Affairs a communication to the effect that in reply to the applications which he had made to Austria, Sweden and Norway, Denmark, Holland, and Belgium to take part in the exhibition, he had received replies to the following effect—Austria was quite willing to lend her assistance, but considered the time fixed for the opening as too near. Sweden and Norway replied that having taken part in those of Arcachon and Boulogne she had no public funds to dispose of for the purpose. The answer of Denmark was to a similar effect. England has sent word that the question of sending delegates was under consideration, as was the case also in the remaining States applied to.]

UTILIZING FERRUGINOUS SALTS.

MR. ISHAM BAGGS, of Holborn, has, in conjunction with Mr. F. Braby, of Deptford, patented an invention which relates to the treatment and application of the waste wash which results from the operation of cleansing iron by hydrochloric acid for the purpose of depositing zinc and other metals thereon, ordinarily known as the galvanizing process, and which waste wash, although it has occasionally been employed for purifying coal gas, has hitherto been usually thrown away as being altogether useless. In order to neutralize the free acid which may remain in the wash scrap iron may be digested therein, or the free acid may be neutralized by any convenient or suitable means. The wash or liquor should then be filtered or decanted, and upon the subsidence or separation of the impurities, it should be boiled down to a moderate density for the convenience of carriage. The liquor thus obtained contains a proportion of iron in the state of muriate or chloride, and may be employed for various manufacturing and useful purposes, and especially for the manufacture of muriate of ammonia from gas liquor or other ammoniacal liquor or vapour, and which forms the subject of this invention, the muriate of iron, hitherto a comparatively waste and useless product, being thus employed and utilized instead of hydrochloric acid for the purpose of the formation and separation of muriate of ammonia from the gas liquor or other ammoniacal liquor or vapour. The solution of muriate of iron is simply mixed with the gas or other ammoniacal liquor, the ammonia contained in which is thus converted into muriate of ammonia, whilst the iron contained in the first-mentioned solution is converted into carbonate and sulphide of iron by means of well-known chemical reactions. The iron salts together with the tar contained in the gas or other ammoniacal liquor under treatment should be allowed to subside, and be then separated by any of the well-known means. A solution of muriate of ammonia is thus obtained, which should be concentrated by means of heat, crystallized, roasted, and sublimed.

The following is a convenient and useful mode of saving a large amount of the fuel which would otherwise be consumed in evaporating large quantities of gas or other ammoniacal liquor; lime in the proportion of rather more than an equivalent of the same to the ammonia contained in the liquor is added thereto at the commencement of the operation, and the mixture then subjected to heat, when after prolonged boiling nearly the whole of the ammonia will be driven off, and little will remain behind but the water, lime, and natural impurities. The ammonia so carried over may be either condensed with the water which accompanies it, or may be passed directly into the clarified waste wash, which it will immediately decompose with the production of muriate of ammonia and oxide of iron. Ammoniacal vapours may also be treated in accordance with this invention for the production of muriate of ammonia.

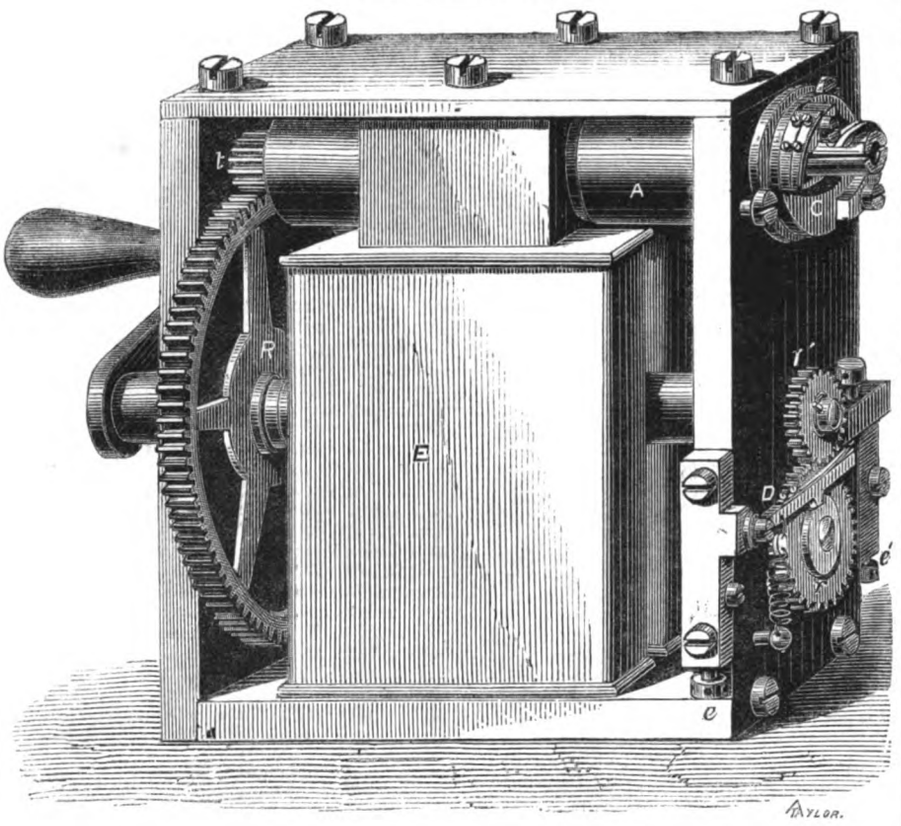
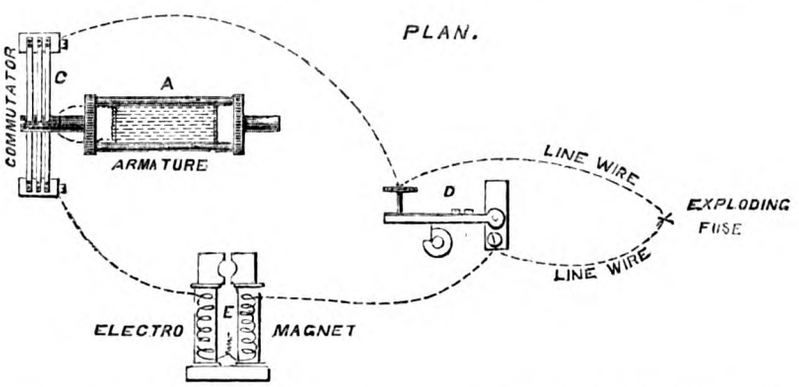
DYNAMO-ELECTRIC APPARATUS.

BY MR. C. W. SIEMENS,





SIEMENS' DYNAMO-ELECTRIC APPARATUS FOR BLASTING PURPOSES.

IT may be remembered that in our late summary of Electricity and Telegraphy, we referred to an instrument of Mr. Siemens, for the purpose of blasting, as being about the only practical application of the new mode of obtaining dynamic electricity by the use of great mechanical force, as originally shown in the large machine exhibited by Mr. Wilde. We now place before our readers some description of this apparatus—looking upon it as a very interesting practical application. The mechanical arrangement of this apparatus is similar to that proposed by Dr. Werner Siemens in 1857, for the production of electric currents, consisting of a cylindrical keeper hollowed at two sides for the reception of insulated wire wound longitudinally, which is made to rotate between a series of permanent magnets. In Mr. Wilde's machine (see the MECHANICS' MAGAZINE, No. 2246, October 18, 1867), these permanent magnets were attached to a "magnet cylinder" divided so as to represent the two poles. Within this cylinder was placed a similar armature to that mentioned above; this revolved at a high rate, and within a very small distance of the cylinder itself. The induced electricity obtained from the armature was passed through a commutator, and used to excite a large electro-magnet fitted with a magnet cylinder and a similar arrangement of armature to the permanent magneto-machine. The essential difference in Siemens' apparatus from that of Wilde's is the absence of the magneto-electric machine as the exciting agent. This is done away with, and a smag electro-magnetic machine alone employed, havin as its exciting agent its residuary magnetism only. The electro-magnet is provided with a magnet-cylinder, within which revolves a small Siemens armature. The coils of this electro-magnet are traversed by the current produced by the rotating armature after being, by means of a commutator, directed to flow in one direction only. At the commencement of rotation the armature is acted upon merely by the weak residuary magnetism of the electro-magnet, and consequently, only weak currents are produced in its surrounding coil. These weak currents passing through the coils of the electro-magnet in the same direction instantly increase the residuary magnetism, thereby again producing increased induction currents in the armature, and so on, until the iron of the electro-magnet has taken up the highest amount of magnetism which it is capable of holding. In this arrangement the coils are short-circuited, and so kept during the revolutions of the handle when current and magnetism are developed to their utmost extent. By now suddenly opening this short circuit, a very powerful current of short duration will pass through a line connected to the terminals.

In the above engraving A is the revolving armature into the pinion of which gears the wheel R; E is the electro-magnet, and C the commutator. Short circuit is established by the lever D, which drops into a notch after two revolutions of the wheel r^1, and thereby opens the circuit. The current therefore enters the line, the ends of which are fixed under the screws e and e^1. By the foregoing, the plan of connection will be readily understood. The wires passing from the armature through the electro-magnet by D. it will be seen how at D the short circuit is broken and a current sent into the line. The apparatus is placed in a wooden protecting case, so arranged that the instrument need not be withdrawn whilst being used. Putting the handle to the protruding square of the spindle of wheel R makes the apparatus ready for use. A small drawer is provided for the reception of the handle. The advantages (especially for exploding purposes) of an instrument thus handy, portable, and useful in all weathers over galvanic batteries and their concomitant inconveniences, as also over static-electric machines, which only act in very fine weather, are undeniable; and it was with a view of producing a useful never-failing instrument of that kind that this apparatus was constructed.

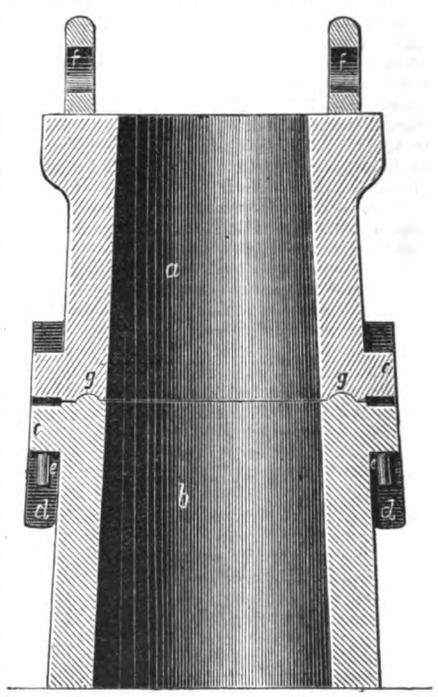
It is only necessary with this instrument that it should be once actuated either by magnetism or by a current from a single cell. After that there is always sufficient residuary magnetism to induce a weak current in the armature. The great practical advantage of this is immense, for we always have at command a never-failing supply of electricity for the special object required. The current induced by this apparatus is also well adapted for the release of clockworks or signal bells for railways, for the direct-action or single-stroke electric bells, and for the sending of currents in rapid succession into a line of telegraph. It has already been tried for the purposes of blasting, and has been found to work with great success. It is, we believe, capable of causing an effect at a greater distance from the instrument than other plans are capable of.

It is identical in principle to the large machine brought before the Royal Society on February 14, 1867, by Mr. C. W. Siemens, F.R.S., &c., and to which we have elsewhere already, on more than one occasion, made allusion.

We hope shortly to be able to give the results of some experiments with this apparatus relative to the various distances fuzes can with facility be exploded.

MOULDS FOR CASTING BESSEMER STEEL.

THE invention, illustrated in the accompanying engraving, is designed to render the moulds employed in casting Bessemer steel or other metals more durable, by so forming them that the lower portion which first becomes deteriorated may be removed and a new portion substituted. Hitherto such moulds have either been made of one solid piece or



divided vertically in halves, the better to release the ingot. These improvements have been patented by Messrs. Waddington and Longbottom, of Barrow-in-Furness, and consist in dividing the moulds horizontally, that is, so as to make a top and bottom portion. The edges of these parts which meet together are grooved or so formed as to fit into each other, and the upper and lower parts are secured together by bolts passing through lugs outside the mould. When

Digitized by Google

preparing a mould for use, a cement is filled in between the joint, and a temporary plug is passed inside the mould to prevent the cement squeezing into the mould. The bolts are then drawn up tight, and the spare cement squeezes out on the outside of the mould. Thus when the interior surface of the lower portion becomes worn or eaten away by the splashing of the metal it can be replaced by another one, the upper part serving many lower ones.

Our engraving represents a vertical section of the improved ingot mould, showing the division of the lower from the upper portion, and the method of holding the parts together. *a* is the upper part of the mould, and *b* the lower, on both of which lugs or shoulders *c* are cast, and through the openings in the lugs the slotted bolts *d* are passed and are tightened up by means of the wedges or cottars *e*, cement being used between the joint, which is constructed in the form of a groove, and a rib fitting therein. When it is necessary to remove the old lower part *b* and attach a new one to the upper part of *a*, the wedges are removed and the parts separated. The upper part of the mould is thus reversed, the lugs *f* being downwards, the groove or recess *g* is filled with a cement made of fireclay and blacklead. The new part *b* is then lifted on to it, and a plug which fits half into *a* and half into *b* is placed in the inside of the mould to prevent the escape of the cement into the mould. The bolts are then drawn up tightly by the wedges, whereby the surplus cement is squeezed out, and the mould is ready again for use. We are glad to be able to add that these moulds are giving great satisfaction at the Barrow Hematite Steel Company's works, where they have a considerable number of tops with the fourth new bottom to each. Every bottom taken off has lasted over the average number of casts that the entire moulds did on the old system. The tops are now expected to last two or three more bottoms, thus showing a great saving over the old system of whole moulds.

STEREOTYPING WITH PAPER.

THIS process is now in common use in all the principal daily newspaper establishments in New York. The "Scientific American" states that it is conducted substantially as follows:—The stereotyper first dries the forme of types upon an iron steam table. The forme is then partially unlocked, and a hand brush is rubbed over the surface of the types, cleansing them preparatory to placing over the entire form a sheet or sheets of thin bank note paper, of the finest quality, previously wetted to ensure the required pliability: This paper being evenly laid over the types, the workman takes a long-handled brush made of short, stiff bristles, with which he beats the wet paper evenly, forcing it into all the depressions of the types, taking care not to break the paper. This work finished, a dampened sheet of thicker but more ordinary paper is placed over the first. This is also brush-hammered down upon the types, and followed by another sheet of paper, thinly coated with a preparation of whiting and starch. Again the brush is used to beat this home, after which a brown paper backing is put on, and then the forme of types, covered by the before-mentioned sheets of paper, is trundled to another steam table, where it is slid under a powerful screw press, several blankets folded over it, and all firmly held down until the paper matrix is dry-hardened, or "cooked," as the workmen express it. The papering process occupies three or four minutes, the cooking about twice as many. The matrix is now peeled off from the forme and prepared for casting, by sifting it with finely powdered borax, which, with a soft brush, is thoroughly rubbed into the sunken surface left by the types.

The surplus borax having been removed, the matrix (which now resembles hard but pliable pasteboard) is ready for the casting box, which is made of iron, either straight or curved, to suit the press bed. Handle irons hold the matrix in its proper place at the exact distance (about half an inch) necessary for the thickness of the stereotype plate, which is made by pouring a quantity of hot type metal into an open end of the casting box. This metal, dropping between one surface of the casting box and the sunken surface of the matrix, fills up the latter without burning it. A few moments are allowed for cooling, and then the matrix is stripped from the warm plate, which is subsequently prepared for the press, by trimming down all thick lines, or chiseling away any superfluous metal, paring off the edges, filing, and otherwise treating the stereotype after the usual manner. Circular saws driven by steam power, and hand cutting machinery of various kinds are used in finishing, the whole operation of stereotyping occupying from fifteen to twenty minutes. A second plate may be obtained from the original matrix, in about two minutes, and almost any number of castings can be taken by careful workmen. In some offices only one mould is taken, this being used for casting the number of plates required for several presses. The stereotype, being an exact reproduction, in solid plate form, of the million or more types originally put together by the compositor, is fastened upon the printing press, and used in place of the types.

The advantage of duplicating the plates is apparent. Two or ten presses, working similar plates, will print off in a couple of hours an edition of twenty or a hundred thousand copies, which formerly occupied so much more time that when ten or twelve-cylinder fast presses become slow, second and third editions were resorted to by editors desirous of giving the public the latest news. Previous to the use of stereotypes for newspaper purposes, duplicate formes were sometimes set up in type, an extra expense to the office adopting this course, which was incurred only whenever a pressure of important news was likely to prevent the formes going to a single press in season for working off the edition. Compositors can now work until three or four o'clock in the morning, and half an hour later half a dozen duplicates of their work may be seen on as many different presses, striking off the printed sheets, units of an immense edition of perhaps seventy-five or eighty thousand copies of some newspaper, all of which are frequently counted and delivered to the carriers and newsmen before the editors, compositors, or stereotypers can reach their homes and retire to rest.

MANCHESTER BOILER ASSOCIATION.

THE last ordinary monthly meeting of this Association was held in Manchester on Tuesday, January 7, 1868, Hugh Mason, Esq., of Ashton-under-Lyne, vice-president, in the chair, when Mr. L. E. Fletcher, chief engineer, presented his report, of which the following is an abstract:—During the past month 356 visits of inspection have been made, and 769 boilers examined, 529 externally, 13 internally, 9 in the flues, and 218 entirely, while in addition 3 have been tested by hydraulic pressure. In these boilers 206 defects have been discovered, 10 of them being dangerous. Amongst these defects we may mention the case of a multitubular boiler, constructed of steel plates, and with a single furnace tube, and which was found to fracture on more than one occasion at the transverse seams of rivets at the bottom of the external shell. This boiler, which had a length of 24ft., a diameter of 5ft. 6in. in the shell, and 3ft. 5in. in the furnace tube, was worked at a pressure of about 50lb. on the square inch, and set underground in a colliery, without any external brickwork flues. Boilers set without these flues are always found to give trouble to a greater or less extent at the bottom of the shell, from contraction, the tendency to which was augmented in the present instance by a severe draught of cold air, caused by the ventilation of the mine, which passed over the naked boiler. It is of the utmost importance that in boilers set in this way, the feed should be dispersed by means of a horizontal perforated pipe placed near to the surface of the water; but it is strongly recommended, in addition, that the hot air from the small flue tubes should be brought underneath the shell before passing away to the chimney, in order to equalize the temperature of the boiler throughout.

A case of external corrosion was met with at a colliery, in a Cornish boiler 22ft. 6in. long, and 5ft. 6in. in diameter. This boiler, which had not been previously examined by the Association, had just been removed from one pit to another, when the inspector found it lying entirely bare at the time of his visit, and made a thorough examination. He found the front plate at the bottom of the boiler wasted away round the blow-out elbow pipe to the thickness of 1-32nd of an inch, while the bottom of the shell was dangerously corroded from one end to the other where it had rested on the midfeather wall. In the second plate from the front end, the overlap and rivet heads were found to be nearly eaten away; the third was reduced to 1-16th of an inch in thickness; the fourth was as thin as a sheet of brown paper; in the fifth the rivet heads were gone; and in the sixth the thickness of metal was reduced to 1-32nd of an inch; and so on, while the inspector knocked a hole through in another part. The manager of the works was quite unaware of the danger, and was about to have the boiler reset in this state. Had such been the case, it could not possibly have worked on for any length of time without explosion, while it is highly probable that it would have burst the first time steam had been got up in it on its new bed.

Mr. Fletcher reports six explosions, by which ten persons were killed and thirteen others injured, while, in addition, the particulars may be given of four other explosions of prior date, which there has not hitherto been an opportunity of doing. Not one of the boilers referred to was under the inspection of the Association.

The following is a statement of explosions from November 23rd, 1867, to December 31st, 1867, inclusive:—No. 29, November 27, plain cylindrical, flat-ended, externally fired, 1 person killed; No. 30, December 23, single flue or Cornish, internally fired, 6 persons killed, and 4 persons injured; No. 31, December 26, particulars not yet fully ascertained, 2 persons injured; No. 32, December 28, "balloon" or "haystack," externally fired, 1 person killed, and 4 persons injured; No. 33, December 30, two flue Lancashire, internally fired, 2 persons injured; No. 34, December 31, plain cylindrical, egg-ended, externally fired, 2 persons killed, and 1 person injured Total, 10 persons killed, and 13 persons injured.

CONSTRUCTION OF THEATRES.

ONLY two days after the destruction of Her Majesty's Theatre, one of the suburban theatres of Paris, Belleville, was completely destroyed in about three hours. When we consider the great size of Her Majesty's Theatre, and the fact that in the case of Belleville the water was frozen, the shortness of the time in which the former was consumed as compared with the latter is startling, yet the construction of the Belleville Theatre was far from perfect, for the floor of the pit gave way and four firemen and a soldier injured, two of them very seriously. Few facts, observes the "Society of Arts Journal," are more remarkable than the small amount of damage done by fire in Paris, yet the number of persons in each house, and, consequently, the number of fires, is very much larger than in London; and, although the number of firemen is three or four times larger in the former than in the latter city, the engines are mere garden toys compared with those of the London brigade, to say nothing of the steam fire-engines. The comparative immunity from fire may be accounted for, in part, by the very crowding of the houses, which would seem to be a source of danger; each family only occupies one floor, and, consequently, there is little chance of a fire smouldering for hours without being discovered, but the grand difference in favour of modern French houses, as compared with those of London, arises from their superior construction.

In the first place, timber is almost entirely banished; the beams, girders, and flooring-joists are all of iron, and the spaces between them filled in with brick arches and mortar; this arrangement not only renders the floors nearly fireproof, but it excludes noise, and affords little shelter for vermin. Then, again, the floors themselves are composed of thick oak parquet, instead of inflammable deal boards; while those of the kitchens, pantries, and offices are mostly of tile. The staircases, it is true, present some danger, but nothing compared to that which surrounds the flimsy constructions in London houses. In theatres and other large buildings, the staircases and passages are of pre-eminent importance, and much attention has been given to these parts in the various recently-constructed theatres of Paris; in some of the old theatres, as, for instance, the Palais Royal, the staircases are of iron. It is only when public attention is excited by such accidents as the destruction of Her Majesty's Theatre, that attention is to be obtained for questions of this kind, and these are the moments when it is important to point to what has been done in the way of improvement elsewhere; within a very few years there have been several important theatres built in Paris, the Chatelet Theatre, Lyrique, and Gaite, amongst the number, while the New Opera House offers, at the present moment, an admirable occasion of studying the newest modes of construction and the precautions adopted by French architects and builders. When we consider what an awful calamity might have happened had Her Majesty's Theatre been crowded with spectators, the importance, nay, the moral duty, of collecting all the available results of study and experience need not be further insisted on.

THE visitors during the week ending January 25 to the South Kensington Museum were, on Monday, Tuesday, and Saturday, free from 10 a.m. to 10 p.m., 11,390; on Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m to 4 p.m., 1,590—total, 12,690. Average of corresponding week in former years, 9,920. Total from the opening of the Museum, 7,165,014. Patent-office Museum.—Number of visitors for the week ending January 25, 4,011; total number since the opening of the Museum free daily (May 12, 1858), 1,236,219.

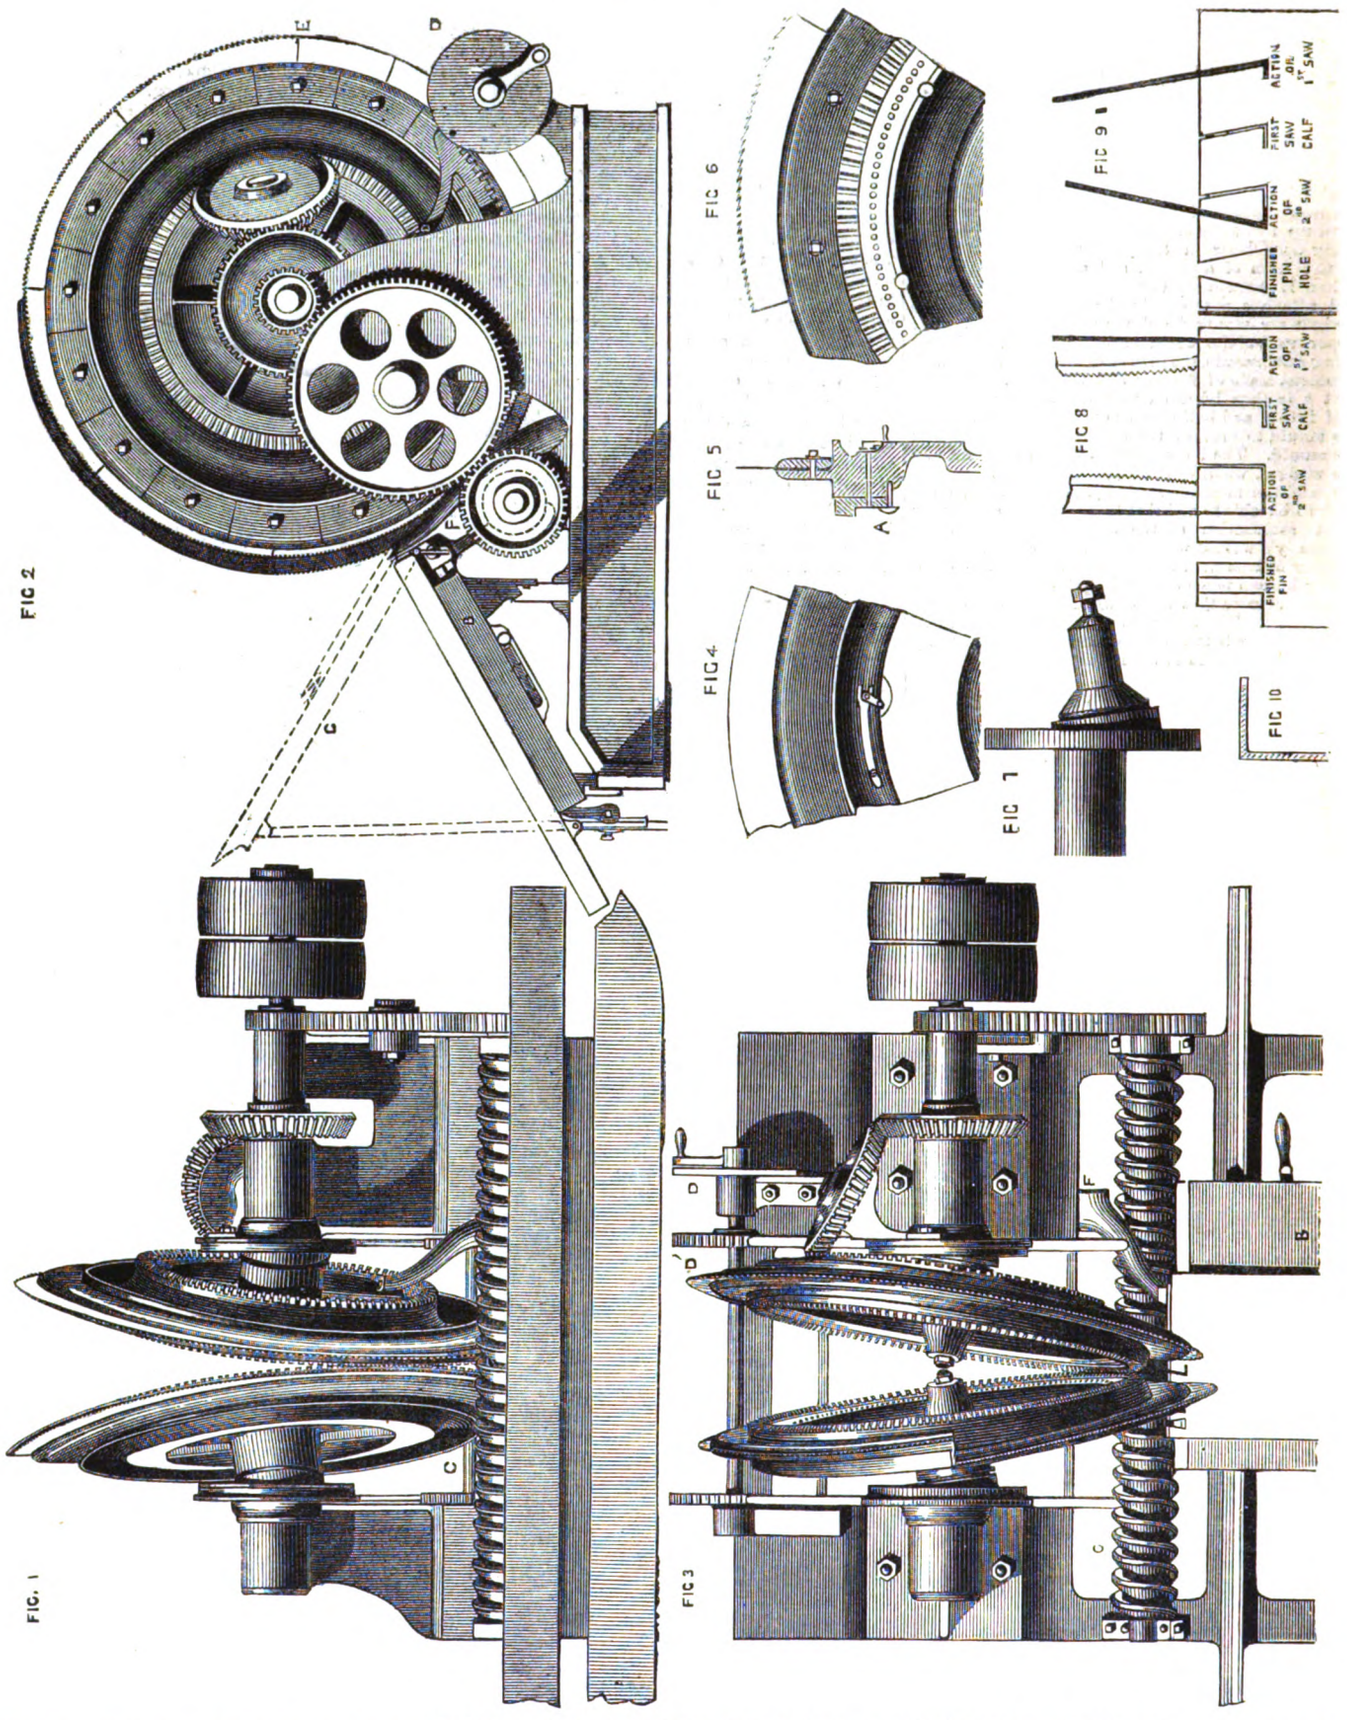
THE AMERICAN DOVETAILING MACHINE.

By MR. S. T. ARMSTRONG.



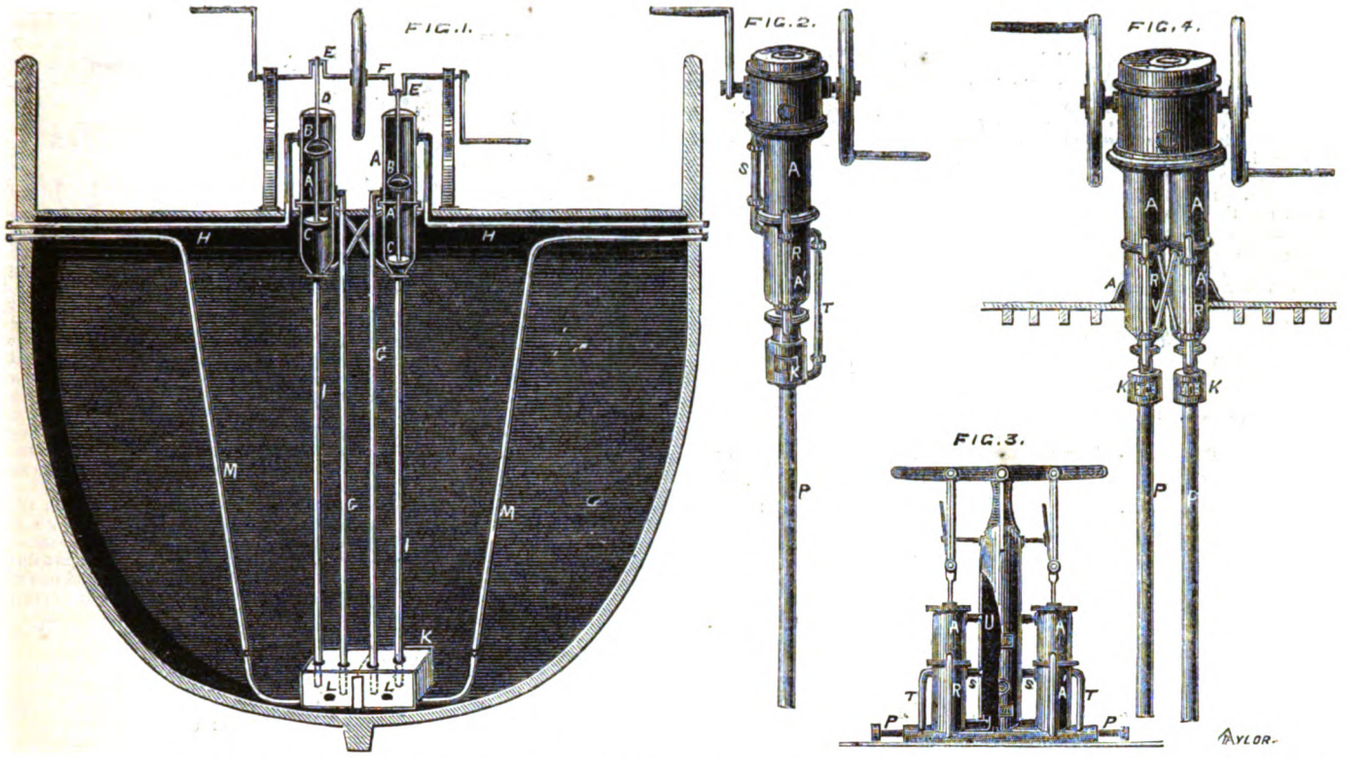
THE AMERICAN DOVETAILING MACHINE.

IN our notice of the machinery at the Smithfield Club Show in December last, we briefly referred to the American dovetailing machine which was at work there, and promised to give our readers full particulars at a future time. We now have much pleasure in placing before our readers detail engravings of this interesting machine. Manifesting as it does the exercise of the highest order of mechanical talent, and the most entire originality, it deserves to be studied not only by that class of manufacturers who are interested in it but all who can appreciate successful novelty in machinery. Though it may appear a small matter, such a tool has really been needed for a long time, and now that we have it it will enable the principle of dovetailing—without which a really strong box or case cannot be made—to be extended to a multiplicity of articles on which it would have been impossible heretofore to use it in consequence of its cost when carried out by hand. Fig. 1 is a front elevation with the table removed in order to show as much as possible of the saws; the machine is shown complete in end elevation in fig. 2, and in plan fig. 3. Figs. 4, 5, and 6, give details of the fixing of the saws. The section, fig. 5, is that of the saw disc on the driving axle, and shows the way in which the annular gearing ring working the other saw disc is capable of being moved round to any point of the circle, and there clamped with the two little pins shown at A (fig. 5); this is a very important point, as by it the relative commencements of cut

Digitized by Google

TREBLE ACTION PUMP.

By MR. F. HOLMES.



of the two saws are varied, and by that means the width of the dovetails; for as the table B, figs. 2 and 3, is moved, carrying the wood, at a uniform speed across the front of the saws, the space between each cut will of course be regulated by the number of degrees of the circle, that the entering point of one saw is behind the other.

The number of dovetails to be cut in an inch, or in any given space, is regulated by moving the half nut connecting the table with its driving screw C, figs. 1 and 3, forward or back half, a quarter, an eighth, &c., of a thread of that screw, by which one, two, or four intermediate dovetails are given between the first ones cut, corresponding with the threads of the driving screw, which, as will be observed by a glance at the gearing, is driven at the same number of revolutions a minute as the saws. The small hand wheel and segment gear, D D, figs. 2 and 3, are for moving the short spindles, fig. 7, of both wheels round together, so as to vary the angle of cut, as described in our former article, and as shown in figs. 8 and 9. When the "pins" are being cut, as in fig. 8, the spindles are turned in such a position as to bring the point of gearing of the saw disc, perhaps 45 deg., remote from the point of contact of the saws with the wood, from which results a pair of cuts diagonal to the plane of the wood but parallel to its grain. When the "holes" are being cut, as in fig. 9, the spindles are turned, so that the point of contact of the saws with the wood is in the same radius with the engaging point of the gearing, and a pair of cuts are made perpendicular to the plane of the timber, but inclined at the usual dovetail angle to its grain. The increasing diameter of the ranges of segmental saws is easily seen on fig. 2, the point where the spiral begins in the driving saw (shaded light) is just at the lower side of the disc, as there represented, and that at which the driven saw (shaded dark, the edge only being seen), begins its spiral, is at the top of the circle; one saw in this case is therefore half a revolution before the other, and the width of the pins will consequently be equal to the width of the spaces cut out between them, as the wood will have travelled over just half its motion for each revolution between the commencement of the saws.

The slight helical pitch of the saw blades is seen in fig. 3; the pitch of their screw is 1in., corresponding with that of the table moving screw, so that the cutting edges may exactly keep pace with the transverse motion of the wood. The way in which the saws are turned at an angle for the last gradient of each circle is shown in fig. 9, and with enlarged section, fig. 10; the point at which the ordinary radical toothed saw ceases, and the angle saw begins, is at E, fig. 2. It is worthy of note in regard to the durability of these saws that each segment can replace its neighbour as it becomes worn down; beginning, say, with the segment which is shallowest, and where the cut first received the last filing up of which it is capable, and must be thrown aside when blunt; it is not then replaced with a new one, but the next of a size greater in depth is moved on, and the whole range follow on, the new segment being the last one with the deepest angle edges, for this substitution is carried on in the same manner past the point where the change from ordinary to angle saws is made by just filing ordinary teeth on the last angle segment, which has by that time been worn down till it has none of the angle left projecting beyond the plane of the blade.

F, figs. 2 and 3, is a scriber, which nicks a line on the under side of the wood as it passes along, serving to define the depth of the dovetail, and to prevent the cross saws from leaving any "burr" on the lower side of the timber; the dotted lines, G fig. 2, show the position to which the table can be elevated in order to cut the kind of corner dovetail work used in small boxes and by cabinet makers, as will be easily seen by the angle at which the wood is held to the saws; in this case they cut out of it at an angle of 45 deg., leaving the corner of the work flush without the dovetail appearing through the plank. In examining this machine it must be borne in mind that the saw discs are free on the short spindles, fig. 7, and not staked on and driven by them, but by the bevel gear, shown in all the drawings, which transmits the power from the short pulley shaft driven by the belt. These short spindles are themselves free to revolve, so that they can be fixed with their inclination in either of the two directions, suitable for cutting the pins and the holes as above described. Mr. S. T. Armstrong is the inventor of this machine, which is making its way into very general use.

TREBLE-ACTION PUMP.

WE show in our engraving some very important improvements in pumps, whereby a treble action is obtained from a single-acting pump with two pistons on the same rod. The improved pump is the patented invention of Mr. Frederick Holmes, of Plumstead, and is arranged in the following manner:—From about the middle of a pump barrel having a double piston, or two pistons, the upper of which is a bucket piston, on the same rod, a pipe is carried down which terminates at its lower end in the liquid to be raised; a pipe leads from the upper part of the barrel to deliver the liquid raised by the first pipe. From the bottom of the pump barrel a pipe is carried down, which also terminates at its lower end in a closed chamber immersed in the liquid with which it is filled. The chamber is provided with inlet valves, and a pipe is carried up from its lower part to deliver the liquid. Mr. Holmes prefers to employ two pump barrels and two sets of pipes, the two pumps acting alternately.

Fig. 1 of our engraving represents two pumps worked from the same shaft, and acting alternately. A is a pump barrel divided by a flange and stuffing box at A^1 into two chambers, and having two pistons B C, the upper of which B is a bucket piston; these two pistons are on the same rod D, which is worked by a crank E of the shaft F, to which rotary motion is imparted. G is a pipe carried down from about the middle of the barrel A, above the stuffing box A^1, to the liquid to be raised. H is a pipe leading from the upper part of the barrel to deliver the liquid raised by the pipe G. I is a pipe carried down from the bottom of the barrel to the liquid to be raised. K is a chamber immersed in the liquid and closed at all points, except that it is provided with inlet valves L. In addition to the pipes G and I, which terminate in the chamber, a pipe M is carried up from its lower part to deliver the liquid.

The action is as follows:—In the down stroke of the pistons B C the liquid in the pipe I is compressed and forces liquid from the chamber K up the pipe M; the liquid thus forced from the chamber K is replaced through the inlet valves L in the up stroke. In the up stroke the liquid is sucked up the pipe G, enters the barrel A between the pistons B C and above the stuffing box A^1, and in the next down stroke passes through the valve of the piston B, so as to be discharged by the delivery pipe H at the next following up stroke. The two delivery pipes H and M may, if desired, be connected. When two pumps and two sets of pipes are used, as in our engraving, the chamber K is divided vertically as indicated by the dotted line N, and when the pumps are fitted to ships the middle of the chamber may be recessed at the bottom, as shown at O, so as to fit over the keelson. By leading a pipe, as shown in dotted lines at V, from the bottom of each barrel A to the upper part of the lower chamber of the other barrel, these pumps are made double-acting.

A modification of this pump is represented in elevation in fig. 2. Instead of the chamber K, fig. 1, fitted with valves being immersed in the liquid to be raised, a valve chamber K is fitted to the lower chamber of the barrel, and the valve chamber communicates with the liquid to be raised by a suction pipe P. R is a pipe carried down from the upper chamber of the barrel to the valve chamber. S is a pipe carried from the upper part of the lower chamber of the barrel to the pump head. T is a pipe carried from the upper part of the lower chamber of the barrel to the lower part of the valve chamber below the valve. In the up stroke the liquid is sucked up the pipe P through the valve chamber and through the pipe R into the upper chamber of the barrel, and also into the lower chamber; at the same time the liquid is forced from the lower chamber through the pipe S into the pump head. In the down stroke the valve in the chamber K is closed, and the liquid is forced from the lower chamber of the barrel through the pipe R to the upper chamber, and through the

Digitized by Google

bucket piston into the pump head; at the same time the liquid is sucked up through the pipe T into the upper part of the lower chamber to be discharged through the pipe S at the next up stroke. Channels can be cast on the barrel instead of the connecting pipes R S T, and the valves brought together and arranged in a valve box instead of being placed in the positions we have described.

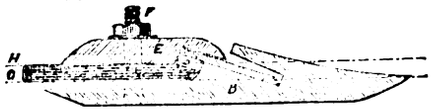
Fig. 3 represents in elevation, partly in section, two of the pumps shown in fig. 2, with an air or water vessel U applied to them to enable them to act as force pumps. By suitable arrangements of the valves, the upper chamber of one or both of the pumps may be used for forcing air into the air vessel to keep up the pressure. Fig. 4 represents two pumps constructed like that represented in fig. 2, but without the communications S and T respectively between the upper part of the lower chamber of the barrel and the pump head, and between the upper part of the lower chamber of the barrel and the lower part of the valve chamber; instead of this a pipe V is fitted between the upper part of the lower chamber of one pump and the lower part of the lower chamber of the other pump, and *vice versa*, so that in the up stroke of one pump the liquid above the piston of the lower chamber is forced out through the pipe V, and meeting the liquid discharged from the lower chamber of the other pump is discharged with it by the pipe R through the upper chamber. The lower chamber is supplied at its upper part in the down stroke by the pipe V. These pumps are being made by Messrs. Stone and Co., of Deptford.

VIOLIN AND HARP STRINGS.

THE manufacture of strings for musical instruments has been carried on from time immemorial in some of the small villages in the Abruzzi, and at the present time, the Neapolitan provinces maintain their superiority in the production of this article. They require the greatest care and dexterity on the part of the workman. The treble strings are particularly difficult to make, and are made at Naples, probably because the Neapolitan sheep, from their small size and leanness, afford the best raw material. They are made from the small intestines, which must be very carefully scraped; the intestines are then steeped in alkaline leys, clarified with a little alum, for four or five days, until the guts are well bleached and swollen. They are next drawn through an open brass thimble, and pressed against it with the nail, in order to smooth and equal their surface; after which they are washed, spun or twisted, and sulphured during two hours. They are finally polished by friction, and dried. Sometimes they are sulphured twice or thrice before being dried, and are polished between horse-hair cords. The strings manufactured in Italy are noted for their strength, transparency, brilliancy, and clearness of tone. This manufacture was introduced into France by a Neapolitan nobleman, in 1766, who established a manufactory at Lyons. This industry is carried on in various other towns in Italy, namely, Gubbio, Foligno, Bologna, Venice, Vicenza, Padua, Verona, and Bassano.

CUTTER FOR REAPING MACHINES.

THE object of the invention illustrated in the accompanying engraving, is to improve the cutting apparatus of reaping and mowing machines, to enable them to cut closer to the ground, and also to cut the crop below the horizontal bar which carries the fingers and knife of the cutting apparatus in order that the top of the uncut stubble shall not come in contact with the under side of the bar, or not to such an extent as hitherto, and thus friction is avoided. For this purpose the fingers are bolted at intervals to the under side of the horizontal bar, whilst on the upper side of this bar is carried the bar to which



the knives are attached as usual; but in place of the knives being parallel with the finger bar, as hitherto, they incline downwards at an angle, so that their points shall come below and cut the crop on the under side of this bar; the slots in the points of the fingers through which the knife works are similarly sloped downwards.

Our engraving shows a sectional view taken through the knife and one of the guard fingers. A is the guard finger bar having the guard fingers B bolted at intervals to its under side as usual; D is the knife bar resting on an inclined surface at the end of the guard finger bar; this bar has a to and fro reciprocating motion imparted to it in the ordinary manner. C is one of the knives or cutting blades attached to the knife bar and inclined downwards, the slots B¹ in the fingers being also similarly inclined downwards. E is one of the knife holders or guides which are bolted at intervals to the top of the knife bar; F is a through bolt, by which the guard finger B and guide E are fixed to the guard finger bar. By constructing the cutting apparatus of reaping and mowing machines with the cutting blades inclining downwards, the points of the knives will cut the stubble on the under side of the guard finger bar A, as shown by the dotted line G in place of cutting the stubble on the line H or parallel with the top of the cutter bar. Mr. W. M. Cranston, of 77, Upper Thames-street, London, is the patentee of this invention.

TREATING FABRICS FOR DYEING OR PRINTING.

IN the manufacture of carpets composed of jute or flax the yarns have hitherto been dyed in the several colours intended to appear on the surface of the fabric, and the designs or pattern have been confined to the production of stripes or checks or plaids, because the expense of producing an elaborate design or pattern upon such material by the aid of jacquard machinery would be too expensive, thereby rendering it impracticable to manufacture a low priced carpet from such material. It is also well known that the treatment required in producing certain colours upon jute or flax by the process of dyeing has had a tendency to make the fibre brittle, and to destroy its strength and elasticity, and to reduce it even to a dust or powder when exposed to wear. This is particularly the case with red, scarlet, dark green, orange, or other high or full colours when acids or compounds of acids and mineral substances are used at a high degree of heat in dyeing to produce a full and brilliant shade of colour. In experiments that have been made in the colouring of jute, flax, or cotton it has always been found that the strength of the fibre is weakened in proportion to the degree of heat and the strength of the dye liquor employed and the length of time required to obtain the desired colour. Hence in producing such colours as are generally known as high or full shades (requiring great heat and strength of dye liquor) the result has always been to weaken the fibre in proportion to the time required to produce the desired shade. After experimenting for several years in the manufacture of jute, flax, and cotton, and especially in colouring the same for carpets or other goods, Mr. Thomas Crossly, of Bridgeport, Conn., United States, has discovered that elaborate designs in colours may be produced upon fabrics woven of a light or heavy character, and either plain or uncoloured, by submitting the same to a process which will prepare it to receive any desired colour in any design however elaborate, and that the colours when applied will be very durable and will not cause the least injury to the fabric.

The following is the process (which has been patented in England), by which this result may be produced:—The cloth after being woven from the raw jute, flax, or cotton in the ordinary manner is immersed in a bath of water, at, say, from 90 to 120 deg. Fah. in which has been mixed a quantity of either wheat or corn bran, together with subor bi-carbonate of soda. After remaining in this bath for a sufficient length of time to thoroughly dissolve the tannin in the jute or cotton, or the gluten or gum in the flax, the cloth must be removed and washed thoroughly in clean water. It is then to be immersed in a bath of cold water mixed with a solution of crystallized tin and muriatic acid or strong muriate of tin with twenty per cent. of oil of vitriol or sulphuric acid at a strength of from 1 to 2 deg. Twaddell. When the cloth has been impregnated with this bath it is to be again washed in clean water and then submitted to a bath of a weak solution of chloride of lime, after which the cloth is to be washed clean and dried, and it will then be ready for printing or dyeing.

For preparing the fabric to receive Prussian blue or other prussiates a different proportion or strength of preparation to that above mentioned should be employed. For Turkey reds or crimsons any other alkali than that above mentioned, or another bath, may be used to dissolve and clean out the tannin or gum from the fibre, and other well known chemical combinations or mordants may be employed to prepare the fibres or fabric to receive the colour; and other suitable baths or treatment may be employed to bleach or whiten the fabric in lieu of chloride of lime. Thus, instead of chloride of lime, sulphurous acid, or the fumes produced by the combustion of sulphur and saltpetre, may be employed, and a similar or better effect may be obtained. The essential feature of the present invention is that by the process we have described, the tannin or gluten may be removed from the fibres without the least injury to them, and the fibres may be impregnated or mordanted so as to prepare them to receive the colours, and may be bleached in order to obtain a good white.

Carpets or other fabrics dyed or coloured in any colours, or pattern, or design, may thus be produced by the process of dyeing or printing without weakening or injuring the strength of the fibres, and at the same time a carpet or other fabric having all the richness and style of woollen or worsted goods, with equally durable colours, may be produced. This result has never been obtained before by dyeing or printing cloths composed of jute, flax, or cotton, and by this invention carpets may be produced from flax or jute, or cotton, or other vegetable fibre at a price very much less than when made of wool or any other animal fibre, the result of which will be a great benefit to the public.

UNAPPRECIATED GENIUS.

THE following extract from a "hitherto unpublished comedy" is given in the American "Army and Navy Journal." It will be understood by the light of the few remarks on the subject of the proposed American Naval Board of Survey, which we have made in an early portion of our paper.

[SCENE.—*A room in the Bureau of Steam Engineering. Isherwood with his hands to his head. Room in confusion.*]

Isherwood. Oh! you ungrateful country to treat me thus! I might say, with the poet, "'Twas ever thus, from childhood's hour, I've seen my fondest hopes decay." Dash pots and oil feeders! (getting excited). I'll leave the navy, and offer my services to the King of Abyssinia, he will appreciate me, or the King of the Sandwich Islands, he's used to big canoes, and will appreciate my style of vessel. To think that my genius cannot be understood! That Dickinson's at the bottom of all this.

[*Enter Member of Congress from "Scrap Heap" District.*]

Member. Ah! my dear Rear-Admiral, how are you this morning, and why so blue looking? What has occurred to disturb your machinery? Is your cut-off out of order? or don't your air pump work well? or is your expansion contracted more than you can bear? Perhaps your shaft is out of line, and propeller won't work. Or is it, old fellow, that you can't raise steam enough on your boiler to keep up with your ambition.

Isherwood. Cease this railing, "I'm not in the vein." I'm going to leave the country, and go to Timbuctoo, and see if I can't work expansively there.

Member. But, my friend, what good will that do? You can't find enough iron there to build one of your engines; they have only enough for arrow heads.

Isherwood. I'll take brass enough with me there to build all the engines I want.

Member. But tell me, Ben, is it true that you broke up Dickinson's engine that cost 400,000 dols., and threw it into a scrap heap? Mind how you answer, I'm a committee of Congress; but I notice you say so in your report.

Isherwood. Did I say that? Well, it must be so. I broke it up because Dickinson said: "Consider the lilies of the field, they toil not, neither do they spin; but I say unto you that even Solomon, in all his glory, was not arrayed like one of these." He meant me, with all my laced clothes on, and his engine went into the scrap heap for it.

Member. But could you not have sold it for something, and placed the money in the treasury; the country is much oppressed with taxes, and economy is all the fashion now.

Isherwood. Economy, taxes, oppressed country, what has that got to do with steam? "No pent-up Utica contracts our powers," we work expansively without any cut-off. I don't study economy anywhere. The only economy I think of is economy of space, that is to build ships that will hold the largest quantity of machinery, and leave room for nothing else.

Member. But tell me, Ben, why is it that your ships won't go after all this amount of engine is put in them, and they don't make over seven knots at sea?

Isherwood. That's all gammon. Dickinson pays all the navy fellows to say the ships don't go. I have nothing, in fact, to do with the ship's going. My engines all go, I can swear to that. Now you see we want more scientific men in the line, and, in their absence, we scientific engineers must take charge. Do you understand mathematics? If you don't, you can't comprehend me and my system. In any right-angled triangle the square of the hypothenuse is equal to the sum of the squares of the other two sides, and any parallelopipedon may be changed into an equivalent rectangular parallelopipedon equal to the versed sine of the square root of ten, by which you can tell to an ephography how many tenpenny nails it would take to shingle a bird's nest.

Member (in astonishment). Is that so?

Isherwood. Yes sirree! and if you will read my book you will see it all proved there.

Member. But to return to our muttons, Ben, why won't the Wamp-a-what's-her-name go after all the money that has been spent on her, and how about the twenty-four engineers looking after her

Isherwood. She will go when I choose to let her. I am just trying to see how much coal can be consumed in a given time, to find out how long our coal mines will last after I get all my vessels in motion, and I have to keep twenty-four engineers there to watch Dickenson's men, who are all around trying to put his cut-off on to my engines.

Member. Is that so? Well, people do lie! But, Ben, how is it that in this time of sore distress you slip into the estimates for yards and docks the following sums:—New York yard, 805,410 dols.; Portsmouth, New York, 150,000 dols; Boston.: 416,850 dols.; Norfolk 25,456 dols.; Pensacola 29,146 dols; besides asking for so many millions,, when you already had so much money on hand?

Isherwood. If, sir, you can't understand the square of the hypothenuse and the parallelopipedon hypothesis, you can't be made to comprehend my system of estimates. They are all based on the most abstruse mathematics. They are, sir, a tub to

Digitized by Google

the whale. I have no idea that Congress will pass them, but the mechanics will bite at them, and overlook all I have said to their disparagement in my report.

Member. On what grounds do you claim to be made a rear-admiral?

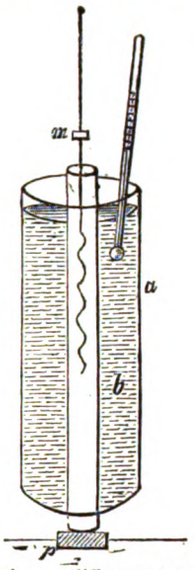
Isherwood. On the theory of expansion. I think our corps wants superheating, and to have each grade superheated to something higher. I have only ranked over three grades since my first entrance into the navy, and I want to expand till I burst.

Member. That will evidently soon occur, for you are, now, Ben, very much in the condition of the frog who wished to outswell the ox. Good morning.

[EXIT. *Curtain drops.*]

A THERMOMETER UNAFFECTED BY RADIATION.

DR. JOULE has communicated to the Literary and Philosophical Society the following method of constructing a thermometer which is unaffected by radiation. In our engraving, *a* is a copper tube about one foot long, and has a tube open at both ends in the centre. Water is poured into the space between the two tubes. In the centre tube there is a spiral of fine wire suspended by a filament of silk, and having a mirror at *m*. There is a lid at *p* which can be removed at pleasure from the lower end of the tube. When *p* is situated as in the figure, there can be no draught, and consequently the spiral with its mirror is at zero of the scale. But when *p* is removed, there is a current of air which turns the spiral, if the



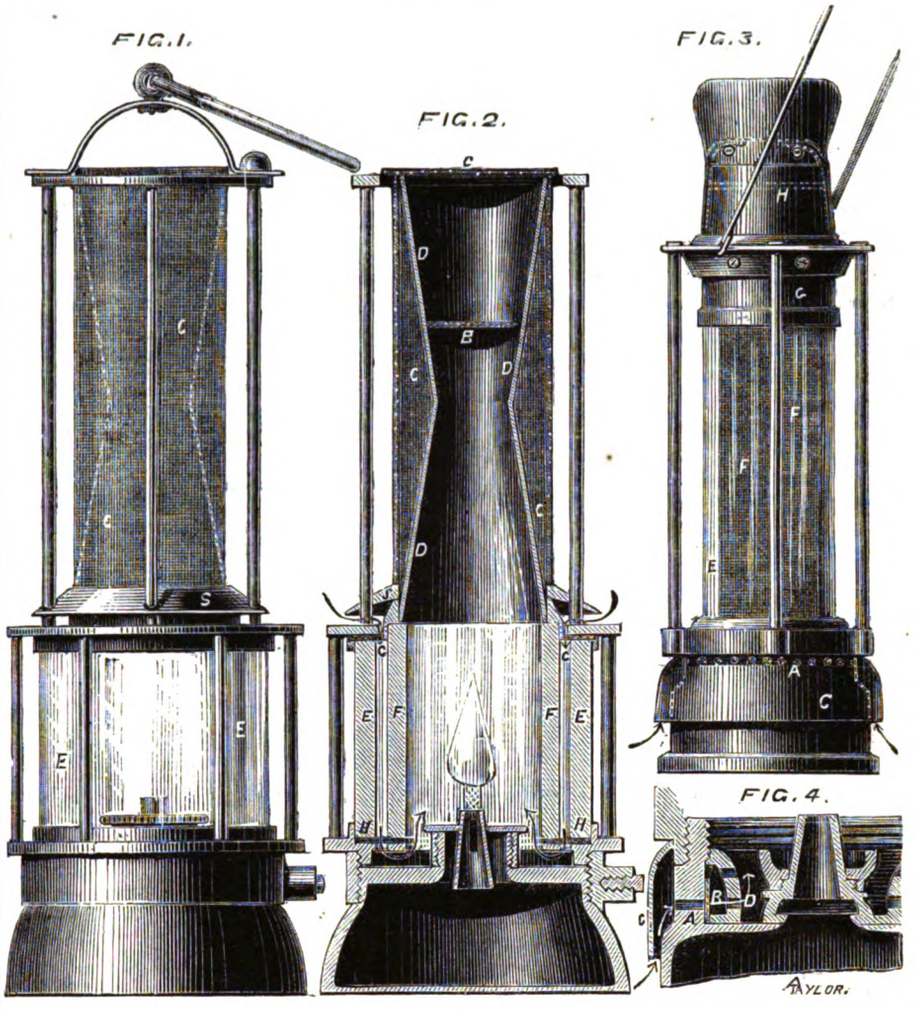
air in the tube has a different temperature from that of the outside atmosphere. In Dr. Joule's apparatus, one deg. Fahrenheit produces an entire twist of the filament. He finds that the temperature in the tube is generally warmer than in the outside atmosphere of a room, which must be owing to the conversion of light and other radiations into heat on coming into contact with the copper tube. The Doctor has tried the apparatus in the open air on a still day, with the same result. Of course when there is wind the effect is masked, but by increasing the length of the tube, making it 30ft. for instance, and using certain precautions, Dr. Joule thinks this difficulty may be overcome.

QUEKETT MICROSCOPICAL CLUB.

THE usual monthly meeting was held at University College on Friday evening, Mr. Arthur E. Durham, president, in the chair. Mr. M. C. Cooke read a paper on The Hairs of Indian Bats. He described and illustrated the microscopical characters of hair from forty-five species of cheiroptera found in India and the countries contiguous thereto. This subject possesses a special interest from the fact that a kind of bat hair from India has been used as a test object for twenty-five years, without its source having been scientifically determined. The paper was illustrated by forty-five diagrams, which, together with 100 slides of the various hairs, mounted, dry, and in balsam, were presented to the club at the close of the meeting. A discussion followed, and a vote of thanks was given to the author. Eleven new members were elected, and the meeting terminated with a *conversazione*.

MINER'S SAFETY LAMP.

By Mr. D. P. Morison.



MINER'S SAFETY LAMP.

MR D. P. MORISON, of Pelton Colliery, near Chester-le-Street, Durham, mining engineer, has just patented the miner's safety lamp shown in the accompanying engraving. His improvements relates firstly, to lamps in which the air necessary to support combustion is admitted through perforations above the cylinder or cylinders surrounding the flame; and, secondly, to lamps in which such air is supplied through perforations below the said cylinder; and are designed to prevent, in an explosive mixture, any communication between the flame of the lamp (or any ignited gas inside the lamp) and the surrounding explosive mixture, even when the explosive mixture presses against the lamp at a high velocity. In lamps where the air enters above the cylinder surrounding the flame, Mr. Morison employs for the top of the lamp, in lieu of the metallic wire gauze now generally in use, a cylinder of sheet iron or brass forming a chimney. In this chimney he places, at short intervals from each other and from the top, discs of wire gauze or perforated copper. By this means he effectually prevents any communication between the exterior surrounding explosive mixture and the interior of the lamp by the top of the lamp. The air for sustaining combustion is admitted at the top of two cylinders of glass surrounding the light through a ring of wire gauze, and is conveyed downwards between these cylinders to the wick of the lamp after again passing through one or more rings of wire gauze or perforated copper placed near the bottom of the cylinders. Over the top of these two cylinders is placed a protecting shield of wire gauze, in order to break the force of any strong current of explosive mixture. By these means a lamp is formed which has been proved by experiments to be practically safe, even in a strong current of explosive mixture.

Fig. 1 of the accompanying engraving is an elevation, and fig. 2 a vertical section, of Mr. Morison's lamp. E F are two cylinders of glass having an annular space between them, down which the air necessary for sustaining combustion passes, as indicated by the arrows; G is a ring of wire gauze at the top of the annular space, and H represents one or more rings, also of wire gauze, at the bottom of the space through which rings the air passes before entering the inside of the lamp. S is a protecting shield to break the force of a strong current of explosive mixture. D is the chimney forming the top of the lamp, and composed of two converging cones of brass or other metal. B is a disc of wire gauze inserted in the upper part of the chimney D. C is an outer cylinder of wire gauze, which, however, may be dispensed with.

In lamps in which the air is admitted through perforations placed at the bottom of the lamp, the air is made to pass under a protecting shield of brass or other metal through a series of perforations, then through a ring of wire gauze and another series of perforations before reaching the flame. In this lamp is a cylinder of glass which entirely surrounds an interior cylinder of wire gauze, and prevents any current whatever of air or explosive mixture reaching the interior of the lamp. A lamp constructed in this manner has been proved by direct experiment practically safe, not allowing the flame to pass, even at very high currents. Another benefit obtained is the obviating, by means of the shield, of any obstruction by dust or other matter to the passing of the air through the perforations. Fig. 3 is an elevation, and fig. 4 a vertical section, of the lower part of a lamp constructed in the manner just described. C is a shield to protect the perforations from strong currents of explosive mixture, and from becoming obstructed by dust or other matter. A is an outer series of perforations; B a ring of wire gauze, and D an inner series of perforations, through whtch two series of perforations and ring of gauze the air for sustaining combustion must pass before reaching the flame. E is a glass cylinder entirely surrounding an interior cylinder F of wire gauze. G is a socket into which the upper part of the glass cylinder E fits. H is a disc of wire gauze at the top of the lamp.

A NEW opera house has been erected in New York. It is built of white marble, and its architecture is Italian. One of its fronts is 120ft., and the other 112ft. wide, and the building is 325ft. long. The entrances lead into a vestibule, 40ft. wide, 80ft. long, and 30ft. high. From this ante-room a staircase leads to the dress circle of the house. From the front row of the dress circle it is 185ft. to the footlights. Above is the family circle, below the parquet, and the house will seat 2,600 people. From the floor to the ceiling is 70ft.; the stage is 70ft. deep, 80ft. wide, and 50ft. high.

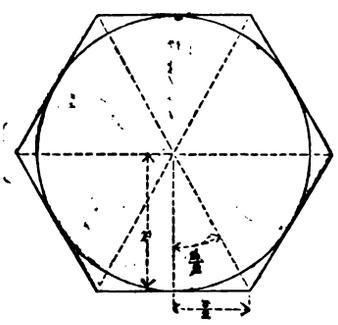
Correspondence.

SQUARING THE CIRCLE.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I see from your impression of January 3, that Mr. Harvey is still writing about the squaring of the circle, in spite of his having been quite unable to demonstrate his proposition. Up to the present time your correspondents (including myself) have only shown that there is a hitch in Mr. Harvey's demonstration. I intend to show now that Mr. Harvey's proposition is an absurdity. For this purpose I shall demonstrate that Mr. Harvey's value for the area of the circle is as near as possible equal to the area of a regular polygon of thirteen sides circumscribed to his circle.

For my demonstration I must presume that Mr. Harvey allows the values of the trigonometrical functions in general, and of the tangents in particular, to be correct as given in any table of logarithms, or any other collection of mathematical tables. Mr. Harvey must allow the correctness of these tables, because all the values contained in them can be calculated without making in any way use of the ratio of the diameter of the circle to its circumference.



For any circumscribed polygon of n sides of the length s, the area, A, is $A = n \frac{s}{2} r$; r being the radius of the inscribed circle.

From the diagram it will be seen that:

$$\frac{s}{2} = r \text{ tg. } \frac{a}{2} = r \text{ tg. } \frac{360^\circ}{2n} = r \text{ tg. } \frac{180^\circ}{n}$$

If this value of $\frac{s}{2}$ is substituted in the equation for A, we find

$$A = n r^2 \text{ tg. } \frac{180^\circ}{n};$$

and for a polygon of thirteen sides we find

$$A = 13 r^2 \text{ tg. } \frac{180^\circ}{13}$$
$$= 13 r^2 \text{ tg. } 13^\circ\ 50'\ 45'',6$$
$$= 3{,}20414\ r^2$$

If the same calculation be made for a circumscribed polygon of fourteen sides, we find

$$A = 14 r^2 \text{ tg. } 12^\circ\ 51'\ 25'',2$$
$$= 3{,}19536\ r^2$$

The first calculation shows that Mr. Harvey's formula gives the area of the circle only about 0,128 per cent. smaller than the area of the circumscribed polygon of thirteen sides. This is not very remarkable, but it is most extraordinary that according to the second calculation the area of the circumscribed polygon of fourteen sides is actually 0,144 per cent. smaller than the area of the circle, calculated by Mr. Harvey's formula. Of course all the circumscribed polygons of more than fourteen sides have, according to Mr. Harvey, smaller areas than their circles, which is a clear demonstration of the incorrectness of Mr. Harvey's formula.

Perhaps many of your readers do not understand trigonometry, and are therefore not convinced by the above calculations. If they wish to be convinced that Mr. Harvey's formula is an absurdity, I advise them to strike a circle of 1 foot diameter, and to draw the circumscribed regular polygon of twenty sides. If the drawing be made with the necessary precision, they can (with a rule divided in 1-100th of an inch) measure the sides $= 1'',90 = 0{,}15833\ldots$

This side multiplied by $\frac{1}{4}$ radius $= 3'' = 0{,}25$ gives the area of one of the twenty triangles, and the sum of the twenty triangles gives the area A of the polygon.

$A = 20 \times 0{,}15833\ldots \times 0.25 = 0{,}79166\ldots$ square feet. (The exactly calculated area is $= 0{,}79191$ square feet).

Now, according to Mr. Harvey's formula, the area of a circle of 1' diameter is $= 0{,}80$ square foot; or 0,00834 square foot, or about 1,2 square inches larger than the area of the polygon, whilst everybody can see from the drawing that the polygon is larger by the twenty little triangles between the circle and the polygon, the sum of the areas of which is $= 0{,}00651$ square foot $= 1$ square inch nearly. Before Mr. Harvey goes on proclaiming his (as I have shown) absurd proposition, he would do well to explain, first, how it happens that his circle can have a larger area than the circumscribed polygon of more than fourteen sides.

The area of a circle by Mr. Harvey's rule is too large by nearly 2 per cent., whilst the area found by Mr. Hayden's rule (see his letter in the MECHANICS' MAGAZINE), is only about half per cent. too small.

If, therefore, any one wishes to square the circle by drawing, instead of using a table of areas or a good slide rule, he may use Mr. Hayden's construction, but never Mr. Harvey's rule, which has only shown that Mr. Harvey blundered, and is unwilling, or unable to see his blunder.—I am, Sir, yours, &c.,

January 13. A. W.

SIR,—Your journal is highly appreciated by your cousins on this side of the Atlantic Ocean, as giving for its price an amount of practical information greater than any other similar journal existing; but allow me, also in name of scientific, as well as practical men, to enter our protest against devoting so much valuable space to the vagaries of men who evidently are not clear about the first principles of mathematics or mechanics. It is not only your space wasted, but also the time for the thousands who read your valuable paper. Need I tell you that I refer to the long-winded letters on the quadrature of the circle by a certain Mr. William Harvey, 10, Albert-terrace, Albert-gate, London, S.W., and also the answers and criticisms on those letters, found in almost every number of the MECHANICS' MAGAZINE since October last.

Already in 1610 Ludolf van Ceuler published his book on the circle, containing the famous Ludolfian number for the circumference of 35 decimals; this book was then published to refute the theories of those who, without understanding much of geometry, already at that time pretended to have discovered a particular method of finding the relation of the diameter to the circumference, but, of course, always came to a number larger than a certain circumscribed polygon, or smaller than a certain inscribed polygon, which, of course, shows at once some error in their demonstration. Since that time, about every year, some publication appears, either in England, France, Germany, Holland, &c., of some very deficient mathematician who thinks he has made a discovery in this line. I have before me two books and three pamphlets, published here during the last decade, on this very subject; the authors all find an erroneous ratio, and some even, to save their theory, maintain that the circumference lays outside of the circumscribed polygon, as soon as this has a great many sides. Mr. Harvey goes further than any of them; the circumference of his circle, being 3 and 1-5th diameter, lays outside the circumscribed polygon of 16 sides. However, Mr. James Smith, according to the London "Athenæum" of 1861, beats him in this respect; the circumference of his circle is 3 and 1-3rd diameter, and is thus outside the circumscribed polygon of only 8 sides. Also at that time an amount of notice was taken of Mr. Smith's publication which surprised us here; the British Association even meddled with the subject, the London "Athenæum" devoted more than four columns to it, and Sir Rowan Hamilton published a demonstration against Mr. Smith's conclusions.

During the time (1859-1864) that I was connected with the Cooper Institute in this city, as many as fourteen persons applied to me, stating that they had found the quadrature of the circle, and some ten or twelve others who believed they had found perpetual motion. For the benefit of those persons I published for private distribution a pamphlet containing a condensed historical account of the most important and highly interesting results, arrived at by the researches of men, fully prepared to enter upon the investigation of such a subject. This pamphlet was always presented to any person who called on me upon the above-mentioned errand; it saved me considerable time, which otherwise would have been spent unprofitably.

Those attempts at the quadrature by ignorant persons appear to be a chronic disease of a part of society—a kind of insanity—as mostly it is found impossible to convince them of error. The traditional notion entertained by some of them, that certain governments have promised large premiums for its solution, contributes most surely to keep the contagion alive; but it is high time that all should know that the Royal Society of London, and the Academy of Sciences in Paris, already in 1775 resolved never to examine any more papers on the quadrature, trisection of angle, duplication of the cube, or perpetual motion; those learned bodies found already a century ago, that all would-be discoverers in those problems were either very ignorant or suffered from a kind of mental aberation called monomania. I have sent you here a copy of the pamphlet mentioned above.—I am, Sir, yours, &c.,

P. H. VANDER WEYDE, M.D.,
Late Professor of Higher Mathematics and Mechanics at the Cooper Institute of Chemistry, at the New York Medical College, and of Industrial Science at the Girard College, Philadelphia.

New York, December 26.

[We are obliged by Professor Van de Weyde's compliment, and accept his protest. But in keeping up the fire of the circle squaring discussion, is his practice not a little at variance with his theory? However, as we happen to know that the correspondence interests a number of our readers, we shall continue the discussion until they have had enough, which we think will be soon. We must bear in mind that our readers are not all professors, nor have they all the same turn of mind. With regard to the main question, it practically comes to what the author of "Festus" says in a later poem:—

"Disputed points stand where they always stood,
And doubtless will do till another flood."

and this is the gist of Professor Van de Weyde's letter, for which we thank him, and assure him that his name and writings are neither unknown to nor unappreciated by the readers of the MECHANICS' MAGAZINE.—ED. M. M.]

LETTER III.

SIR,—Geometricians have, I believe, a contempt for a simple measurement as a proof; yet, notwithstanding, I hold the true determination of the length of the circumference of the circle to be one of pure mechanical decision. By means of lathes and planing machines we can obtain a perfect circle and plane; and if Mr. Whitworth, for example, would undertake to do so, and roll a cylinder over the plane in conjunction with a line engraved upon its side and two lines upon the plane to correspond with a revolution, repeated back and forwards several times for correctness, and compare it with the calliper diameter by means of the delicate measuring apparatus which he possesses, I confess I should put faith in it in preference to that of any astronomer computed from the revolution of celestial bodies. For which I have a good reason:—In the first instance, we should have a perfect circle and plane to operate upon; in the second we should not. And I would ask Mr. H. Wood and "R. N.," who have laid such stress upon this mode of proof, where they will find a celestial body making a perfect circle? Take the earth and moon for examples. When the earth is between the moon and sun the joint attraction of the earth and sun upon the moon is greater than when the moon is between the earth and sun, for then their attraction upon it is opposed—so the moon's course cannot be a perfect circle.

With regard to the earth—as the influence of attraction depends upon the quantity of matter, that of the moon upon the earth is in due poroportion, and draws the earth towards herself in her revolutions round it sometimes in conjunction with the sun and sometimes in opposition (proved by the tides), and must give from this cause alone an oblate spiral motion to the earth, so the earth revolves round the sun not in a plain circular line, but in a flattened spiral one; and when, in addition to this, the action of the planets, erratic and other bodies known and unknown (for the theory is that attraction acts through all space), is taken into account, I think I have shown a good reason for my question and preference. However correct in point of time astronomical calculations may agree with the accepted formula of endless decimals, it is not an equal proof of the proportion of circumference and diameter, for the reasons which I have given, namely, that there are no bodies making perfect circles to calculate upon. So, if they agreed, it should rather be a proof that they are not correct than that they are.

But even upon the point of time I would ask astronomers the question, Whether or not they would discover if the earth were temporarily delayed or accelerated on its axis from any cause? For, as the revolution at the meridian is the data of time, what if the meridian (so to speak) were behind or before time, would they do to discover or correct it? Upon this element, nevertheless, rests the proof of those inconceivable arrays of decimals which are given as proportions of the circle, and of which Mr. Harbord is the most moderate of champions, being content in one case with only 27 odd billions as a finite proof, which is a mere drop in the ocean to some others. I am far from an unbeliever that as the course of the earth is influenced by so many and varying causes, its revolution may not also be temporarily accelerated or retarded by some of them, and, therefore, the true time as well. When such a thing happens, the best clocks and chronometers keep the worst time of course. In which case I, for one, possess a very excellent timepiece. Practically, I shall never be brought to the belief that it indicates when the earth is going too quick or too slow. And, touching those wonderful decimals again, I would observe that when we consider that an object is lost to sight that does not show up under a magnifying power of 30 millions of times, what kind of a proportion of two lines is that which is billions of trillions of times less than anything we can possibly see? I quite agree with Mr. Harvey in regarding them as monstrous absurdities, due either to the method by which they are eliminated, or to the imperfect annotation of our numerals.

As this letter has already trespassed at a considerable length, I must beg of you to allow me to complete it at a future time, and show the geometrical method by which I propose to get the circumference of the circle, subject, however, to the most absolute

Digitized by Google

repudiation if it should not agree with the mechanical measurement under the conditions I have stated.—I am, Sir, yours, &c.,
January 21. JOSEPH A. NICHOLSON.

SIR,—May I presume to say that although Mr. J. A. Nicholson's definition of the circle being equal to a parallelogram half the length of its circumference by half its diameter is no doubt correct, yet this was well known long ago, and does not, that I can see hold us to definitely square the circle, but only (if I may coin a word) to parallelogramize it. Perhaps, however, Mr. Nicholson intends to "lead up to a square."—I am, Sir, yours, &c.,
January 24. THOMAS SCUTT.

SIR,—In your impression of January 3, Mr. Harvey, in reply to Mr. Hayden, states "that if he will persevere he can divide and put together mechanically the four spandrils E, and the squares F I G H, so as to be together equal to twice the square F I G H." Now, if Mr. Harvey can do this, why does he not do it at once and settle the controversy between him and his numerous opponents. If he can do it we (your readers) will be happy to follow him in his researches into the pyramidical angles, &c., but so long as he leaves this unexplained, his arguments therefrom must be considered totally unsatisfactory. If he supposes from the flagging of the controversy that his proofs are generally considered satisfactory, he is quite mistaken. If there be really any connection between the Pyramid and the ratio of circumference to diameter, I should be inclined to find it in the angle of the passage 26deg. 40min., the line of which approximates very remarkably to the value of the fourteenth part of the circumference, as calculated by the ratio in common use.—I am, Sir, yours, &c.,
January 27. THOMAS C. HAINES.

PETROLEUM FURNACES.

SIR,—Referring to the letter in your last issue, signed C. I. Richardson, in which the experiments made with Mr. Thomas Crow's patent are the subject of remark, and feeling that it can in no way apply to the patent obtained by our Mr. S. E. Crow, there being in the last-named patent no part of the apparatus exposed to the action of the heat, its principle being to prevent the flames from impinging upon either the boiler or the furnace; and fearing that the names being similar may cause confusion, we should feel obliged by your inserting this letter.—We are, Sir, yours, &c., S. E. CROW & Co.
Chemical Works, Stratford, January 25.

Meetings for the Week.

MON.—Society of Arts.—"Preservation, Preparation, and Culinary Treatment of Foods," at 8 p.m.
Royal United Service Institution.—Captain J. H. Selwyn, R.N., on "Further Information on the Employment of Mineral Oils as Fuel for Steam Ships," at 8.30 p.m.
Society of Engineers.—Dr. Cullen on "The Surveys of Proposed Lines for a Ship Canal between the Pacific and Atlantic Oceans," at 7.30 p.m.
Royal Institution.—General Monthly Meeting, at 2 p.m.
TUES.—The Institution of Civil Engineers.—Mr. A. C. Howden, A.I.C.E., on "Floods in the Nerbudda Valley; with Remarks on Monsoon Floods in India Generally." Discussion upon "Fresh Water Floods of Rivers," at 8 p.m.
Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.
THURS.—Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.
FRI.—Royal Institution.—Professor Huxley on "The Animals most Intermediate between Birds and Reptiles," at 8 p.m.
SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly, payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—G. H.—G. E. P.—H. S. C. and Co.—J. G. N. A.—T. S.—Messrs. D. and M.—J. H.—R. J.—R. B. P.—J. W.—B. F. F.—S. L. L.—J. H.—W. P. M.—Dr. D.—Messrs. C. M. and Co.—J. H.—R. T. B.—W. H.—W. J. M.—R. Naval, Military, and Gunnery Items.

THE "Hercules" has the whole of her armour-plating fixed, the date named for her being floated out of dock being the 8th of February.

A MEMORIAL has been presented to Congress asking for a Government subsidy to support an American line of steamships between New York and one or more European ports.

THE new class of twin-screw composite unarmoured steamers of the "Beacon" class, a complete squadron of which is either completed or building, are to be officially designated as gun-vessels of the second class.

IT is stated that early on Friday morning one of the guns at the fort of Duncannon, Passage West, near Waterford, was spiked. No information is procurable on the subject, and no clue has been found, nor have the police any suspicion of the "spiker."

ON Saturday last, Mr. E. J. Reed, who has recovered from the effects of the late railway accident, paid an official visit to Chatham dockyard, and was engaged for some time in inspecting the iron-clad turret ship "Monarch," and the "Hercules," building from his designs. Mr. Reed also inspected the "Blanche," fitting for a term of service in Australia.

MARSHAL NEIL has lately made experiments in France with the wood gunpowder invented by Capt. Schulze. It is found to be extremely advantageous for rifles, as it leaves no fouling. The English Government should not overlook it, when determining the rifle of the future. The chamber ought to be a trifle larger than for the common powder, as Schulze's powder, though strong, is much lighter.

THE Board of Trade intend to present Captain Antonio M. Budinich, master of the Austrian barque "Ebe," with a binocular telescope, in recognition of his services to the crew (12 in number) of the "Eudora," of Sunderland, who were rescued by him from their sinking vessel on the 30th November last, and landed at Constantinople on the 5th December. Captain Budinich generously refused to accept any compensation for the subsistence of the shipwrecked crew whilst aboard the "Ebe."

THE "Toronto Globe," gives the following account of the Volunteers and Militia of Canada:—There are in Ontario and Quebec 31,194 Volunteers (officers and men); in Nova Scotia 1,002, and in New Brunswick 1,791. The service Militia of Ontario consists of 48,496, that of Quebec numbers 40,545; in New Brunswick there are 35,412 Militiamen, and in Nova Scotia 58,031. The Militia of Nova Scotia and New Brunswick are partially drilled and organized; in the last named province turned out for five days' training during the past year.

MESSRS. HENDERSON, Coulburn, and Co., of Renfrew, have just launched a composite screw of 850 tons, built for the East India trade. This vessel has been named the "Sakura," and she is being now fitted by the builders with a pair of compound engines of 110 horse power, nominal. Messrs. R. Duncan and Co., of Port Glasgow, have contracted to build a paddle for Messrs. J. Brymner and Co., of Greenock. Messrs. Robertson and Co. have contracted with Mr. J. Kincaid, of Glasgow, to build and engine a saloon steamer for the South American river trade.

ON Saturday last an experiment was made at the Lyons Railway Station as regards the transporting of cavalry and infantry per train in fewer carriages than have hitherto been used for the purpose. A company of sappers, another of gendarmes, the band of an infantary regiment, two squadrons of Curiassiers and of the Carbineers of the Guard, were ordered down under the command of M. de Langalerie—horses and men in marching order. The object was first to try whether twelve men with their horses could travel in the space hitherto occupied by eight. Whether this was accomplished is not stated.

WRITING from Malta on the 22nd, the "Times" correspondent says:—Lieut-Col. Clarke, Royal Engineers, Director of Admiralty Works, returns to England by the present mail, without any settlement having been come to regarding the long-pending harbour question between the Admiralty and the Malta Government, which, as the Chief Secretary to Government stated at the last sitting of council, has weighed for the last eight years like an incubus on the island. The offer which Colonel Clarke has been authorized to make respecting the valuation of the property in the French creek is said to be substantially the same as that which had been previously rejected. The question will now have to be settled by correspondence.

Miscellanea.

WE read that a man at Detroit has skated 60 consecutive hours for 500 dols. Towards the last, blankets had to be held about him to keep the wind from blowing him over.

IN Berlin there is some fear of a temporary failure of coal, as the merchants had not laid in a sufficient supply, and it is just possible that some of the manufactories may have to stop work for want of steam power.

THE total production of anthracite coals in the United States during 1867 is estimated at 12,750,000 tons, an increase of 250 tons over the yield of 1866. 214,000 tons of coal, mainly cannel, were imported from Great Britain during 1867.

THE council of the Aeronautical Society have decided upon holding an exhibition in London of objects connected with aeronautical science, in the month of June. Arrangements have been made for the exhibition to be held at the Crystal Palace.

LAST week two young men were buried under a mass of earth while at work in a chalk pit, at Farningham, Kent. They were soon extricated, and conveyed by train to St. George's Hospital, Hyde Park, where it was found that both had sustained compound fracture of the legs, besides other serious internal injuries.

EXPERIMENTS were recently made with the electric light in the gardens of the Royal Horticultural Society by the Royal Engineers stationed at the South Kensington Museum. Many of the Fellows feel interested in the question of illuminating these gardens, and we understand that further experiments are contemplated during the coming season.

THE Havre journals speak of a dreadful tempest which burst over that place a few days back. The sea rose and carried away not only the whole of the palisade at the Gosset baths, but destroyed several of the bathing machines, damage being caused on that point alone to the extent of 4,000f. The works in course of execution for the Maritime Exhibition were much injured, and two blocks of masonwork for the gallery blown down.

A TABLE published in the "Moniteur" shows that the highest price of land in Paris is generally for places in the neighbourhood of the theatres. Thus, the various sites near the Theatre Francais, either in the Rue Richelieu, the Avenue Napoleon, or the Place in front, have fetched per square metre 1,056f., 1,200f., and even 1,300f. Near the new opera the figures have varied from 600f. to 1,040f., the new Vaudeville from 1,000f. to 1,250f., the Gaite from 450f and upwards.

ANOTHER very interesting discovery has been made near Malton. Last week workmen commenced getting up clay in a brickyard at Norton, and at the depth of nearly 4ft., found a very fine and quite perfect rubbed flint axe. The implement is 6¼in. long by 2in. wide at the cutting edge, and has the other end tapering to a point. The axe is of the chisel shape. The discovery was made about 150 yards from the river Derwent, and but a short way from the ancient intrenchments at Malton.

WE hear that a new line of telegraph is likely to be laid from the Tyne to Denmark, which promises to give not only much cheaper messages to Denmark, Norway, Sweden, and the north of Russia, but much greater speed and accuracy. One-fifth of the whole capital for this line, it is said, has been subscribed by the Danish Government; altogether, £85,000 has been already subscribed; and the specification for the cable is to be settled by the Danish Government. The United Kingdom Telegraph Company are to work the line direct from London to Copenhagen—a distance of about 1,000 miles.

ONE of Vivian's tunnelling engines was in operation at Mr. Greaves's slate quarry, Festiniog, last week, but with what amount of success it is difficult to say, as the engine, it would appear, has not been satisfactorily put to work, only two instead of three boilers generating the air by which the revolving apparatus, to which about forty-eight drills are fixed by means of screws, is worked. When the three boilers are at work, the men attending the engine entertain the most sanguine expectations of its successful operation. The level is driven through the slate rock, in close proximity to the hard rock which separates the main vein from the new vein, as it is called.

RECENT letters from America state that the track of the Union Pacific Railway, to which line we made special reference in our last, has been laid to a point 540 miles west of Omaha, and is now said to be "down" within ten miles of the rocky mountain range known as the "Black hills." It is said that the track is laid loosely, and with no view to permanence, the object of the contractors being to secure the Government subsidy as soon as possible. The road has been built with Government funds, in fact; before it can be made secure or profitable, it must be re-laid over at least half its length. This accounts for the wonderful rapidity with which the line has been made.

A LETTER from St. Petersburg, in the "Nord," states that a chemist of Simbirsk has established in that town a laboratory for analysing the various soils of the province which require manuring. Simbirsk s a Russian Government district situated on the Wolga, and is of considerable extent. It has been proverbial for the richness of its black soil, or humus, which is of more than usual depth, but which for many years past has become less and less productive. During the last seventy years the yield of the crops has diminished by fully one-half, and, besides, the quality of the wheat has deteriorated. The land is evidently becoming exhausted, and the Agricultural Society of Simbirsk has very favourably received the proposal of constituting a laboratory for experimentalising.

IN Captain Shaw's analytical list, the fires of the past year are assigned to some 125 different causes, including "unknown." Candles, gas, and flues seem to be the most prolific source of this kind of danger, having led in the course of the past 12 months, the candles to 205, the gas to 130, and the flues to 116 fires. To children playing with lights and lucifers 39 cases are attributed; smoking tobacco, 32; stoves, 24; hot ashes, 22; lucifers, 22; naphtha and paraffin lamps, 21; turpentine, fat, pitch, resin, and similar substances boiling over, 19. Six houses were set on fire by the inhabitants waging a war of fumigation against bugs and beetles with reckless ardour. A cat managed to burn its master's dwelling by upsetting a box of lucifers, and another disaster was due to a parrot playing with vesuvians.

SINCE the abandonment of the gigantic undertaking contemplated by the late directors of the North British Railway in the formation of a bridge over the Firth of Forth from Blackness to Charleston, where the water is about two miles broad, a project has been started for the erection of a swing bridge across the river a little above Alloa. The proposed bridge would shorten the distance between Fifeshire and Glasgow by about ten miles, and the towns of Dundee, Cupar, Dunfermline, and Alloa would be benefited in their communication with the west of Scotland to that extent. The line would leave the Stirling and Dunfermline section of the North British Railway a little to the west of Alloa, and cross the river on an iron bridge with a central span of 200ft. wide, opening at certain states of the tide to admit the passage of vessels.

RUSSIAN railways are rapidly on the increase. The Ryasan-Morschansk line, a portion of the Moscow-Volga line has just been opened. It is 150 miles long, and has taken only a year and three months to construct. The Koslow-Woronesh Railway, a link in the long line to be laid down between Moscow and the Sea of Azof, will be completed in a few weeks; the Moscow-Odessa Railway is progressing so fast that it will, perhaps, be finished this year; and the works between Poti and Tiflis, a line which, after its extension to the Caspian harbour of Baku, will monopolize a considerable portion of the Persian trade, have just begun. The man to whom Russia is indebted for the rapid development of her railway system, and whose name will not be forgotten in the annals of her might and culture, is Herr Von Delvig, a Courland baron, Government director of railway matters.

THE gentlemen intrusted with the responsible duty of procuring salmon ova from the rivers of this country for transmission to New Zealand have now procured their required stock of impregnated spawn. The operations in the river Severn were completed at Worcester, and about 40,000 ova obtained from that river, under the sanction and personal superintendence of the Board of Conservators of the Severn Fishery District and its officers. Among the fish captured with nets for this purpose were some remarkably fine ones, 28 salmon taken in one draught averaging 20lb. apiece, and some being of from 30lb. to 35lb. Not a single clean fish was captured. Mr. Ramsbottom, of Clitherhoe, in Lancashire, was the operator, assisted by Mr. Vowben, who will have the charge of the ova on the voyage to New Zealand. All the fish when operated upon were returned to the river, and the fishermen believe that some of them would not recover their rough treatment.

A MAGNIFICENT upright steam rolling-engine has just been constructed at the South Brooklyn Engine and Boiler Works, United States, for the Trenton Iron Company. An immense cast-iron open pedestal sustains the cylinder, steam-chest, and connections, the connecting-rod and crank work inside the column near the bottom. The fly-wheel and spur-wheel are secured to the shaft by three massive feathers forged on the shaft, the intervals between which and lugs cast in the interior of the hubs are fitted with hard wood wedges, intended to receive and diminish the jar and concussion to which an engine employed for driving rolls must be subjected. The fly-wheel is 22ft. diameter, and weighs nearly 25 tons. The cylinder is 46in. diameter, and the stroke 40in. The total weight of the machine is 67 tons 13 cwts. The engine is calculated to make 75 revolutions per minute, at a steam pressure of 80lb., and is, although extremely compact, of 1,200 estimated horse-power.

IT is about six years since gold was first discovered in any appreciable quantity in Nova Scotia, and for a good while after the discovery was made, very little comparatively was done in developing this source of national wealth. Gradually, however, the matter has been making progress. And it is now believed that, considering the extent of the gold producing area, the quantity of quartz mined, and the number of men employed, Nova Scotian goldfields are the most productive in the world. Since 1862 about 120,000oz. of gold, or nearly 3½ tons, have been secured, amounting in value to nearly 2,500,000 dollars. The yield in 1867 has not been less than 30,000oz., or about 600,000 dollars, almost half the value of the yearly yield of coal in Nova Scotia. In the Sherbrook district the average yield per miner engaged has risen from 562 dollars in 1862 to 1,669 dollars in 1867. There has been as much as 117oz. of gold got from a ton of quartz, and the average yield over all has been 1oz. and 3gr.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1735, 1742, 1749, 1814
BUILDINGS AND BUILDING MATERIALS—None
CHEMISTRY AND PHOTOGRAPHY—1808
CULTIVATION OF THE SOIL, including agricultural implements and machines—None
ELECTRICAL APPARATUS—1750, 1755, 1770, 1771, 1772
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1733, 1734, 1743, 1744, 1752, 1758, 1774, 1795, 1807, 1825
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—1751
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1792, 1796, 1805, 1811, 1812
GENERAL MACHINERY—1753, 1756, 1760, 1761, 1768, 1769, 1777, 1779, 1781, 1783, 1799, 1801, 1802, 1809, 1813, 1816, 1818, 1820, 1821, 1823
LIGHTING, HEATING, AND VENTILATING—1668, 1673, 1748
METALS, including apparatus for their manufacture—1739, 1747, 1767, 1784, 1803
MISCELLANEOUS—1738, 1745, 1746, 1754, 1759, 1763, 1765, 1766, 1775, 1776, 1780, 1782, 1786, 1788, 1789, 1790, 1797, 1800, 1804, 1815, 1817
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1736, 1737, 1740, 1762, 1773, 1793, 1798
SHIPS AND BOATS, including their fittings—1697, 1778
STEAM ENGINES—1787, 1791, 1822
WARFARE—1757, 1785, 1806

1717 S. W. WOOD. *Improvements in apparatus for elevating and moving grain, and for weighing and moving grain.* Dated June 11, 1867.

This invention is not described apart from the drawings. —Patent completed.

1718 J. FLETCHER. *Improvements in the construction of retorts for manufacturing and reburning animal charcoal.* Dated June 11, 1867.

This invention is not described apart from the drawings. —Patent completed.

1719 W. ROWAN. *Improvements in machinery for heckling or cleaning flax, hemp, and other fibrous material, and for preparing the same for spinning.* Dated June 11, 1867.

The patentee claims the combination with holders for the fibrous material of ribbed rollers which act upon the fibrous material, such rollers having some of the ribs formed with serrated teeth, or with heckle pins, all being constructed and arranged substantially as described with reference to the drawings.—Patent completed.

1720 J. C. FULLER. *An improvement in telegraphic insulators, and in caps or shields for the same.* Dated June 11, 1867.

This invention consists in making porcelain or other insulators, and the iron or other caps or shields for the same, with perforations or apertures. The invention cannot be described in detail without reference to the drawings.—Patent completed.

1721 J. MILLWARD. *A combined step cover and wheel fender for carriages and other vehicles.* (A communication.) Dated June 12, 1867.

This invention relates to a device for preventing the accumulation of mud and dust on the steps of carriages and other vehicles, and also for guarding the clothes of the rider from coming in contact with the wheels on entering or leaving the vehicle, and consists in attaching to, or hinging upon, the door of the carriage a flexible plate of sheet steel, or other suitable material, the lower part of which is fitted with a bar having one end hinged or coupled to a loop formed in a flange upon that side of the step which corresponds to the hinging of the door.—Patent completed.

1722 J. F. BOETIUS and J. EICHHORN. *Improvements in the manufacture of types for printing.* (A communication.) Dated June 12, 1867.

In carrying this invention into effect the inventors first prepare by the electrotype process a plate of copper, or any alloy or suitable metal harder and more durable than the well-known type metal, with type heads ranged in proper rows. They then moisten the plate with hydrochloric acid, saturated with zinc, which plate is afterwards rubbed with an alloy of tin and zinc. The plate is next placed in a corresponding mould, and is then strongly heated on a glowing or very hot plate. In this state the type metal (which can either be of common type, or any other cheaper metal, metallic compound, or alloy), is cast thereon to the required height.—Patent abandoned.

1723 J. COCHRANE. *An improved pontoon bridge, also applicable as a life raft and lighter.* (A communication.) Dated June 12, 1867.

This invention consists in arranging a series of two or more pontoons, or long buoyant bodies, by preference hollow metal vessels, of comparatively small transverse dimensions, connected together by a trellis framework arranged similar in principle to a "lazy tongs"—namely, so as to turn upon the connecting pins and to open out or fold together in such manner that the parts of the framing then lie closely side by side. Upon this framework is placed a deck or flooring, the separate boards of which are all hinged together, so as when not in use to fold together backwards and forwards.—Patent completed.

1724 C. D. ABEL. *Improved appliances for horse shoes as a substitute for roughing.* (A communication.) Dated June 12, 1867.

In performing this invention a strong belt is provided at one end with a jaw, which fits over the inner edge of the front part of the horse shoe; the lower part of the jaw is furnished with a spike or "brob," serving as the "roughing" to the front part of the shoe. The other end of the bolt has a screw thread formed upon it, and passes through a tapped bush in a bridge piece extending across the heel of the shoe and taking purchase against the two inner edges thereof.—Patent abandoned.

1725 D. and D. CRIGHTON, and W. DONBAVAND. *Improvements in looms for weaving.* Dated June 12, 1867.

This invention relates to the swells in the shuttle boxes of looms, and consists in improvements for enabling the shuttle to have an easy motion in the shuttle boxes:—First, instead of the ordinary swells, the patentees employ at each end of the lathe a combination of an ordinary inclined swell with a curvilinear pressure apparatus oscillating on an axis as the shuttle travels in and out of the shuttle boxes. Second, they combine the ordinary inclined swell with a curvilinear pressure apparatus revolving intermittently on an axis as the shuttle travels. Third, they apply to the ordinary inclined or curved swell, at either side of the fulcrum, a supplementary spring action, or its equivalent, for the purpose of regulating the pressure of the swells, so as to enable the shuttle to have an easy entrance and delivery in and out of the boxes, and give at the same time the required pressure on the stop rod and swells when the shuttle arrives at the ends of the boxes.—Patent completed

1726 F. D. FROST. *An improvement in rollers used in frames for drawing and spinning or preparing fibrous materials.* Dated June 12, 1867.

This invention consists in forming the front rollers used in frames for drawing and spinning or preparing fibrous materials with a groove in its periphery, and in placing in the bottom of this groove leather, or other suitable yielding material. The ordinary lower roller or boss works in the groove and draws the fibrous material through.—Patent abandoned.

1727 J. H SNELSON. *Improvements in axles and boxes, and in securing wheels thereto.* Dated June 12, 1867.

This invention consists in forming a flange or flanges at the outer end of the axle to receive and hold a metal collar thereon. According to one arrangement, the wheel box fits over the axle, and is secured thereon by placing the metal collar between the flanges, the outer end of the wheel box abutting against the collar. The collar cannot leave the axle under all ordinary circumstances; however, to afford greater security, the inventor unites the ends of the collar by a wire or other piece of metal secured by a screw or pin passing into the end of the axle, and the ends inserted in apertures formed in the collar. An ordinary cap is screwed on to the wheel box.—Patent abandoned.

1728 A. M. CLARK. *Improvements in the manufacture and treatment of white lead, and in apparatus connected therewith.* (A communication.) Dated June 12, 1867.

The apparatus for performing this invention cannot be described without reference to the drawings.—Patent completed.

1729 T. S. PRIDEAUX. *Improving wine on draught, and of apparatus that may be used for that and other purposes.* Dated June 13, 1867.

This invention consists, chiefly, in preventing the access of free oxygen to the wine by supplying it with an atmosphere of carbonic acid gas as the wine is drawn off, whereby the wine will be preserved from becoming sour up to the last, even if it has not been brandied.—Patent completed.

1730 E. T. HUGHES. *Improvements in the manufacture of brushes, and in the machinery or apparatus employed therein.* (A communication.) Dated June 13, 1867.

This invention relates to brushes made from bristles and other similar materials, the object being to secure the bristles in the back or stock of the brush, without the application of a false back to the brush, or without the means employed for securing the bristles being visible upon the back of the brush. The bristles are secured in a solid back or stock by first drilling holes partly through the back or stock, and then inserting a bunch of doubled bristles into each of the said holes with a wire staple, the ends of which, on being pressed down to the bottom of the hole, turn longitudinally or laterally into the wood or material of which the back or stock of the brush is formed, and thus draw the wire tightly around the bristles so as to secure them firmly in the back or stock.—Patent completed.

1731 A. C. LION. *Improvements in the manufacture of chains, bracelets, necklaces, and other similar articles of jewellery.* Dated June 13, 1867.

These new articles of jewelry are formed of two distinct parts, each of which is prepared separately, and which are afterwards connected in such manner as to cause them to form one body, the meshes, loops or mails of which are connected in an invariable manner, but so as to impart to the jewel the required suppleness and pliability, no other soldering being made use of than that required for finishing the terminal ends of the jewel.—Patent completed.

1732 J. HOLMES. *An improved combination of materials to be used in the manufacture of drain bottoms, flue slabs, bricks, and other like purposes.* Dated June 13, 1867.

This invention consists in the admixture of the scale or shale found in clay beds underneath the clay with the clay itself, or the admixture of the scale or shale with the "seat" found underneath coal in its bed as well as with the clay, by preference in the proportion of five-sixths of the former to one-sixth of the latter, the scale or shale having previously been pulverized and mixed with water to render it of a pasty consistency, and then blended or mixed with the clay, moulded to the required shape, and burnt in the customary manner.—Patent completed.

1733 F. B. BAKER and L. LINDLEY. *Improvements in stretching or tentering, and in dressing or finishing lace or other fabrics, and in machinery or apparatus employed therein.* Dated June 13, 1867.

This invention relates, first, to improved means of stretching or tentering lace or other fabrics in dressing frames. For this purpose the patentees mount one or more of the pins or hooks upon which the fabric is fixed upon separate bars working upon rods or bars running the length and breadth of the frame at the sides and ends thereof. Second, the invention relates to improved means of distributing the dressing or stiffening material upon the fabrics to be dressed or stiffened, and for this purpose they employ a box in which the dressing or stiffening material is placed; this box is provided with a roller working in the dressing or stiffening material, and other rollers

Digitized by Google

fixed one underneath the box and one at each side thereof. Around these rollers an endless sheet or cloth is passed, and on the ends of the two outside rollers are fixed flanged or grooved pulleys, which run upon and are supported by a suitable tramway formed by preference of wire stretched between suitable framing formed on or fixed to the dressing frame, such flanged or grooved pulleys serving to support the distributing apparatus, and at the same time to give motion to the endless sheet or cloth carried thereby.—Patent completed.

1734 R. H. BARTON. *Certain improvements in apparatus to be employed in the preparation of cotton and other fibrous materials.* Dated June 13, 1867.

This invention relates to drawing frames, &c., and the improvements consist in the use of apparatus for bringing the ordinary stop motion into action when the can is full, and this apparatus consists of a pawl fixed on the ordinary rocking shaft, which pawl gives an intermittent motion to a ratchet wheel mounted on a shaft, at the end of which is a worm gearing into a worm wheel, and on this worm wheel shaft a finger is fixed, having a projection on one part of its periphery; between this finger and the usual "spoon levers" a lever extends, so that as the finger is caused to rotate by the rocking shaft, pawl and worm and worm wheel once in each revolution, the finger raises the lever which lifts the ordinary spoon lever over which the "sliver" passes, and which brings the ordinary stop motion into action, as though the sliver had broken, and so stops the delivery of more sliver to the cam, whereby waste of sliver is prevented, and a regular weight of sliver is delivered to the cam.—Patent completed.

1735 J. GLOVER. *Improvements in furnaces for steam boilers and other uses.* Dated June 13, 1867.

The patentee claims arranging or combining bars or surfaces for supporting the fuel in steam boiler and other furnaces so that such bars or surfaces may be formed alternately broad and narrow to admit the air in passing up to the fuel supported thereby in limited quantities and varying distances, substantially as described.—Patent completed.

1736 S. HANCOCK. *Improvements in apparatus to be used in signalling in and from railway trains.* Dated June 13, 1867.

In order to enable the guard or other person on a railway train to communicate with the engine driver, the patentee mounts in the guard's van, or in other convenient part of the train, an apparatus consisting of bellows and an air vessel, and the bellows are worked when required by power taken from one of the axles of the running wheels of the train; they force air into the air vessel, from which it passes to a large bell whistle, which it causes to sound, and within the bell is a piston which can be raised or lowered by means of a handle, so as to vary the note of the whistle and so convey any pre-arranged signals. In order to enable the passengers to give an alarm in case of danger, one of the axles of each of the carriages has a cam fixed upon it outwards away from the axle; as soon as the cam has passed, a spring causes the sudden return of the arm, and in this motion the other end of the arm, which is furnished with a hammer head, strikes a bell, and as these motions are rapidly repeated, the bell is loudly sounded, more especially as he uses, by preference, two such hammer arms striking on opposite sides of the bell. In order to lay fog signals on the rails from a train in motion, he employs a holder which receives the fog signal, and which when the fog signal is to be laid, brings it down so rapidly on to the rail that the forward motion of the train during the time required for the operation may not affect the laying.—Patent completed.

1737 W. KING. *Improvements in apparatus for communicating between the guard and driver and passengers and guard of a railway train.* Dated June 14, 1867.

For this purpose the inventor carries a cord or chain through tubes or eyes along the tops of the carriages on one or both sides (so as to work in either direction without turning the carriages), or it may be in the centre of the roof, the said cords being connected by links between each carriage.—Patent abandoned.

1738 C. ASKEW. *Improvements in refrigerators for cooling worts and other liquids.* Dated June 14, 1867.

This invention relates to the employment of a double series of tubes through which water is caused to circulate, and over or around which the wort or other liquid is caused to flow, and consists, essentially, in a novel arrangement whereby the water is caused to flow in two streams through alternate sets of tubes, one set of tubes being fixed, and the other set movable, so as to afford facility for cleansing the refrigerator.—Patent abandoned.

1739 S. TUDDENHAM. *Improvements in the construction and manufacture of iron or metal rail rods or bars for balconies, gates, railings, and pillars, and also in the machinery employed therein.* Dated June 14, 1867.

The patentee claims, first, producing ornamental bars or rods of the kind mentioned in the title by twisting prepared bars or rods having their surfaces so prepared or ornamented as to produce a twisted bar or rod of a given ornamental section or surface, as described. Second, the use of machinery constructed and arranged as described for the purpose of twisting metal bars.—Patent completed.

1740 D. E. MCMAHON. *Improvements in saddles.* Dated June 14, 1867.

In constructing pack saddles the inventor forms the saddle trees in such manner as to admit of their being adjusted to the animal which is to carry the saddle. For this purpose he connects the saddle trees together at the top over the back of the animal by two screws, the one over the other, which, when turned, draw the parts in which they are fitted together.—Patent abandoned.

1742 S. E. CROW. *Improvements in apparatus to be used in connection with steam boiler and other furnaces to adapt them for burning creosote and other combustible liquids.* Dated June 14, 1867.

In carrying out this invention the patentee allows a small stream of creosote or other oil to fall from a pipe in front of the furnace, and blows it in by a jet of high pressure, or superheated steam, as it falls.—Patent completed

1743 G. KER. *Improvements in apparatus for drying or finishing garments and fabrics after cleaning or dyeing.* Dated June 14, 1867.

In place of holding the garments or fabrics in fixed frames, the inventor employs movable frames that can be run upon rails into and out of a drying chamber. Each frame is for this purpose provided with rollers to run upon rails into and out of a drying chamber heated (by preference with steam) by a coil or coils of pipes.—Patent abandoned.

1744 J. FLETCHER and W. CARR. *Improvements in or applicable to machines for sizing yarns or threads preparatory to weaving, and also to slubbing and roving frames, and to other machines.* Dated June 15, 1867.

First, these improvements consist in causing the yarn or thread to pass through the size, while subject to as little strain as possible, by driving each beam from which the yarn is drawn by friction or by frictional contact with a roller. Second, the invention relates to the mechanism for measuring and marking the yarn, which may be applied to other measuring purposes.—Patent abandoned.

1745 J. QUIN. *A new or improved fire-escape.* Dated June 15, 1867.

This apparatus consists of a support and ladder. The support is constructed of a rectangular horizontal frame, similar in principle to the boards used by painters, which rests on the window sill or frame, and is formed of strong iron bars strengthened by cross pieces. To the two side bars of this frame are fixed two longitudinal pieces or bars to form guides or slides for receiving in a suitable position two vertical iron bars, adjustable at any parts of the guides by means of pins attached to chains, and passing through holes in the guides and vertical bars or uprights.—Patent abandoned.

1746 T. WALKER. *Improvements in the manufacture of a spring hook, catch, or fastening, known as Nicholls and Walker's patent.* Dated June 15, 1867.

This invention consists, in the first place, in cutting out of metal a solid blank with lugs on each side hollowed out, and so arranged that the long ends act as a spring hook when doubled or bent about the middle; one end is so formed as to lap slightly over the other ends. Second, the inventor cuts out of metal a blank somewhat similar with arms on either side. The one to be pierced, so as to allow a pin to be inserted, and when the end is closed round the said pin, to hold it firm; the other end is to be pierced and turned in such a shape as to receive the point of the said pin, thereby making a kind of brooch fastening, the long ends to be so arranged and shaped into the spring hook as aforesaid.—Patent abandoned.

1747 J. ONIONS. *Improvements in the manufacture of iron and steel.* Dated June 15, 1867.

This invention consists in the mixture of crude pig or scrap cast iron with a certain quantity of wrought scrap iron, and with a certain portion of charcoal, ammonia, potash, salt, or other chemical ingredients containing one or more of the last-named materials.—Patent completed.

1748 G. MCKENZIE. *Improvements in the manufacture of illuminating gas.* Dated June 15, 1867.

The patentee claims, first, the manufacturing of illuminating gas by using for that purpose a compound, or compounds, of coal and oleaginous or fatty matter, such compound, or compounds, being made substantially in the improved manner described. Second, the manufacturing of illuminating gas by mixing gas made in the manner referred to in the preceding claim with gas obtained from common coal, or from cannel, or similar coals. Third, the obtaining of a slight increase in the illuminating power of gas obtained from common bituminous coal, or from such coal mixed with more or less cannel, or similar coal, by adding to such coal or coals oleaginous or fatty matter in the proportion of not more than fifteen gallons of oil to every ton of coal. Fourth, the adding of about sixty pounds of resin to the ton of any of the gas-producing compounds described, in order to increase the illuminating power.—Patent completed.

1749 C. SADDLER. *Improvements in furnaces for consuming smoke.* Dated June 15, 1867.

According to this invention, in place of injecting steam into the chamber of the furnace containing the fuel, as practised in some arrangements, the inventor causes numerous jets of steam to be injected from the outer surface or ashpit between the fire bars, so as to pass through the burning fuel into the furnace.—Patent abandoned.

1750 R. BEARD. *Improvements in flexible galvanic batteries, applicable to medico-electric purposes.* Dated June 15, 1867.

This invention is not described apart from the drawings, —Patent completed.

1751 A. M. CLARK. *Improvements in the means of cooling beverages, also applicable for preserving substances from the action of heat.* (A communication.) Dated June 15, 1867.

The inventor uses a glass with double sides and fills the annular space with water, which is then converted into ice, in a similar manner to icing a "carafe." A thickness of ice is thus formed, and the drink being served in the vessel will be kept cool until the ice is melted.—Patent abandoned.

1752 W. E. NEWTON. *Improvements in the preparation of pulp for the manufacture of paper.* (A communication.) Dated June 15, 1867.

This invention consists in submitting wood reduced to fragments to the action of steam in a close vessel, the temperature of the steam being greater or less, according to circumstances, and causing the disintegration of the wood by the simultaneous action of the pressure of the temperature and the dissolving properties contained in the steam, which disintegration is finally effected by ordinary mechanical means; also rendering the bleaching operation cheaper and easier by the previous immersion of the wood in any suitable solution.—Patent completed.

1753 G. ALLIX. *Improvements in drilling machines and hoisting machines.* Dated June 15, 1867.

This invention cannot be described apart from the drawings except at great length.—Patent abandoned.

1754 C. ERBA. *Improvements on depilation and leather tanning.* Dated June 15, 1867.

This invention has for its object the shortening of the tanning process. The operation consists in soaking the skins in a bath composed of the following ingredients:—Ninety-six parts of water, two parts of carbonate of soda, and two parts of hydrated oxide of lime, and reduced to a milky state. The skins, being well stripped of hair and washed in running water, are afterwards immersed from four to ten hours in a bath composed of a hundred parts water and a half of ammoniacal liquid. Instead of this, a bath of ammoniacal carbonate may be substituted, containing one per cent. of the said salt. After being washed and scraped again the skins are immersed in a first bath of tannin marking two to four degrees of density, Beaume. In this bath the skins remain from ten to fifteen days, after which they are placed in a second bath of six to seven degrees for four to ten weeks.—Patent completed.

1755 C. and S. A. VARLEY. *Improvements in electric telegraphs.* Dated June 15, 1867.

We cannot here give space to the details of this invention.—Patent completed.

1756 W. R. LAKE. *Improvements in saws and saw teeth.* (A communication.) Dated June 15, 1867.

This invention is not described apart from the drawings. —Patent completed.

1757 G. CLARK. *Improvements in guns, projectiles, and cartridges, and in the construction of the same.* Dated June 15, 1867.

We cannot here give space to the details of this invention.—Patent abandoned.

1758 L. J. CROSSLEY and J. SUNDERLAND. *Improvements in machinery for oiling wool or fibre to prepare it for carding, combing, or other treatment.* Dated June 15, 1867.

This invention is carried out in the following manner:—Over the endless apron or gill combs, or other instrument, which carries the wool or fibre forward continuously, and in a thin layer, there is mounted a trough containing oil; along this trough from end to end an axis passes, and near each end extremity of the trough there is a disc fixed upon the axis, and wires or rods are strained between these discs, and as the axis revolves the wires or rods dip into the oil in the trough, and emerge with oil adhering to them. There is also extending from end to end of the trough a stationary brush, so placed that the strained wires or rods as they come up out of the oil strike the bristles of the brush in passing them, and by these means the oil which the wires or rods take up is thrown off in a fine spray on to the surface of the wool or fibre.—Patent completed.

1759 R. W. BARNES. *Improvements in metallic pens and pen-holders conjointly.* Dated June 17, 1867.

This invention consists in forming one or more holes, notches, indentations, or projections in suitable positions upon the length or periphery or edges of the pens as conveniently to allow corresponding projecting tongues or nibs, projections, or indentations formed on the holder, or upon any suitable form of spring disposed in the holder, or upon a spring disposed upon or forming part of the surface or periphery of the holder, to engage or lock at right angles to the length of the pens, into one or more of such notches, holes, indentations, or projections, when, by so locking in, together with the action of the spring pressing at right angles or obliquely upon the longitudinal edges, or against the surface or periphery of the pens, such pen will be kept perfectly steady in position, and will be prevented slipping into or dripping out of the holder whilst being used or coming out of the holder whilst being wiped.—Patent completed.

1760 J. MEIKLEJON. *Improvements in machinery or apparatus for lifting, lowering, and transporting heavy bodies.* Dated June 17, 1867.

This invention consists in mounting a gantry on or under an overhead turn-table.—Patent abandoned.

1761 J. FLETCHER and W. CARR. *Improvements in sewing machines.* Dated June 17, 1867.

This invention relates to the mechanism or arrangements for feeding the fabric to be sewn, and consists in arranging the two surfaces between which the cloth is fed so that both will move with the cloth when fed, and before they move back again for the next stitch one of the surfaces is lifted or removed from the fabric, so that both surfaces can move back without dragging or pressing upon the fabric, and at the same time leave the fabric at liberty to be freely turned.—Patent abandoned.

1762 C. D. ABEL. *An improved apparatus for utilizing the power spent in stopping the motion of carriages and machinery, as also the power produced by carriages and other vehicles when moving down inclines.* (A communication.) Dated June 17, 1867.

This invention consists, namely, in utilizing the power spent in stopping or retarding the motion of carriages or other vehicles when moving down inclines by causing such motion or excess of power to compress air in strong receptacles, which compressed air is afterwards usefully employed in starting or accelerating the motion of vehicles or machinery.—Patent completed.

1763 J. H. JOHNSON. *Improvements in wood screws, and in the means employed in their manufacture.* (A communication.) Dated June 17, 1867.

This invention relates, first, to wood screws, and particularly to those known as gimlet-pointed screws, and consists in forming in the shank of the screw one or more longitudinal grooves, flat sides, or indentations, which extend upwards from the point of the screw, and are transverse to the thread of the same. The second part of this invention has reference to the tools for cutting the threads on the improved or other wood screws, and consists in the employment for that purpose of a cylindrical or other suitable curvilinear form of tool, whether a complete cylinder or only a segment of the same.—Patent completed.

1765 J. WELCH. *Improvements in swivels for fishing tackle, and for other purposes.* Dated June 17, 1867.

The patentee makes the box or case of the swivel of a piece of metal tubing of the required length, the tube being open at both ends. To one end of this tube he attaches, by soldering, a bow or loop made from a piece of wire. He makes the shank or stem of the swivel of a piece of wire, the head or knob being situated within the bow or loop, and he twists and fashions the opposite end of the said wire into an eye or loop.—Patent completed.

1766 J. E. BOYCE and R. HARRINGTON. *Improvements in umbrellas and parasols.* Dated June 17, 1867.

The patentees claim applying to the runner of an umbrella or parasol a lever, one arm of which is made to engage with one or other of two studs or projections on the stick of the umbrella or parasol, so as to fix the said umbrella or parasol in its open or closed position, the said lever being used in conjunction with a longitudinal channel in the runner for enabling it to slide over the studs or projections on the stick without obstruction, substantially as described and illustrated in the drawings.—Patent completed.

1767 F. B. MILLER. *An improved method of toughening brittle gold bullion, of refining alloyed gold, and of separating therefrom any silver they may contain.* Dated June 17, 1867.

This invention has for its object the toughening of brittle gold bullion, and the refining of alloyed gold (whether naturally or artificially alloyed) whilst in a melted state, with the separation therefrom of any silver they may contain. This the patentee effects by means of chlorine gas, or hydrochloric acid gas, which latter

Digitized by Google

should be mixed with atmospheric air or oxygen, brought in contact with the alloyed gold when the metal is in a molten state; in this manner the silver present, and any baser metals which render the gold brittle, are converted into chlorides, whilst the gold remains in a purified and tough condition.—Patent completed.

1768 I. G. LLOYD. *Improvements in machinery for compressing air.* Dated June 17, 1867.

This invention consists in so arranging the gearing for transmitting motion from the driving shaft of a steam engine to the reciprocating piston of an air pump that, whilst the driving shaft of the engine revolves at an even speed, the piston of the air pump may, at the commencement of each stroke, move with a quicker motion than towards the end of the stroke. In order to effect this the patentee employs differential toothed wheels.—Patent completed.

1769 G. T. BOUSFIELD. *Improvements in indicating time by time-keepers.* (A communication.) Dated June 17, 1867.

This invention consists in causing time-keepers constantly to emit automatically a succession of varying sounds, by counting which, and observing intervals of variation, the time, or approximation to the time, indicated upon the dial may be at any time ascertained, and which may be made to indicate the last hour only, or the last hour and quarters, or still more minute subdivision of time.—Patent completed.

1770 M. GRAY. *Improvements in the manufacture of electrical telegraphic conductors.* Dated June 17, 1867.

The patentee claims the manufacture of electric telegraph conductors by enclosing the insulated wire with strands or threads of manilla, hemp, silk, or other suitable yarn, coated with gutta-percha and bituminous substances, or gutta-percha, tar, and bituminous substances, or with other compounds of gutta-percha.—Patent completed.

1771 M. GRAY and L. GIBSON. *Improvements in means or apparatus employed in examining the coating of electrical telegraphic communicators.* Dated June 17, 1867.

The patentee claims the adoption or combination of means whereby the motion of the creel or bobbin employed in winding coated telegraph conductors during the examination of such coating is dependent on the will of the examiner, in manner substantially as described with reference to the drawings.—Patent completed.

1772 M. GRAY. *Improvements in the manufacture of electrical telegraphic conductors, and in the means or apparatus employed therein.* Dated June 17, 1867.

The improvements relate to, first, coating the several wires which are to surround a central or core wire, or with a substance adapted in the subsequent twisting of these outer wires on the internal or core wire to fill up any space between them. The second part of the improvement relates to drawing the coated wire at separate parts of its progress through the cooling media before winding it on to the reels or creels, in order as much as possible to avoid injury to such coating while it is cooling.—Patent completed.

1773 W. COOKE. *Improvements in means or apparatus for registering the number of passengers carried in omnibuses and other vehicles.* Dated June 17, 1867.

For this purpose the patentee makes use of three chief operating means or agents; first, the motion of the vehicle itself; second, the weight of each passenger when seated; and, third, the weight of each passenger whilst passing on to or off from the vehicle.—Patent completed.

1774 D. SOWDEN and R. C. STEPHENSON. *Improvements in looms for weaving.* Dated June 17, 1867.

This invention relates, first, to means of governing the order of picking, and to operate the picking apparatus in looms wherewith change shuttle boxes are employed at both ends of the lay or batten, and when two or more shuttles are required to be picked from either end in succession; and the improvements consist in having the picking shafts supported at their upper ends in swivel brackets and their lower ends on oscillatory footstep pedestals. These pedestals are connected by a rod which is movable endwise in either direction by the action of a cam operated by the ordinary Jacquard, or other indicating apparatus employed for working the change shuttle boxes, by which the bottom ends of the picking shafts can be moved laterally. The second part of this invention relates to the weft motion, or apparatus for detecting when the weft breaks or becomes used up, and consists, by one arrangement, in dispensing with the ordinary weft fork attached to the knocking-off lever, and instead of which in applying a weft grate at each end of the loom, which is hinged to the front of the batten and embedded in the shuttle race thereof, each having an arm projecting towards the breast beam, which takes into the notch of the weft hammer, or the lever which acts on the knocking-off apparatus when in position for that purpose.—Patent completed.

1775 SIR T. TANCRED. *Improvements in the construction of beehives.* (Partly a communication.) Dated June 17, 1867.

The patentee claims the means described of enabling the combs to be extracted by sliding laterally to and fro, whether the combs are suspended to only a single bar sliding along the guide bars, or are formed within a complete frame, and also by whatever contrivance the bar beneath which the combs are suspended is enabled to slide to and fro, whether by resting by its two ends on guide bars, or in notches or rebates cut into the sides of the box.—Patent completed.

1776 P. WELCH. *An improvement in machinery for rubbing or dressing printers' types.* Dated June 17, 1867.

This invention is not described apart from the drawings.—Patent completed.

1777 W. FAIRLEY. *An improved mechanical arrangement for preventing over-winding in shafts of coal and other mines.* Dated June 18, 1867.

This invention is not described apart from the drawings.—Patent completed.

1778 J. M. FROST. *Improved means and apparatus for raising sunken vessels, which invention is also applicable for preventing vessels from foundering.* Dated June 18, 1867.

This invention consists principally in the use of air-tight bags, buoys, or vessels made of canvas or other suitable material, provided with a nozzle and stop cock, so that they can be inflated or exhausted at pleasure.—Patent abandoned.

1779 C. D. ABEL. *An improved repeating striking movement for watches, clocks, and timepieces.* (A communication.) Dated June 18, 1867.

These movements are worked by one and the same barrel that gives motion to the clockwork. The patent is too voluminous for abstraction.—Patent abandoned.

1780 R. BODMER. *An improved method of securing the nuts of bolts.* Dated June 18, 1867.

This invention has special reference to jointing the rails of railways by means of fish-plates, and consists in splitting longitudinally the whole or a portion of the screwed part of the bolt, and after the same has been put in its place, and the nut drawn up as tightly as may be desirable, introducing and driving into the slit—either in the direction of the axis of the bolt or transversely—a wedge representing a very slightly inclined plane, so as in a trifling measure to expand the two halves or parts of the bolt, and thereby to prevent the nut from becoming loose through the vibrations caused by the passing of trains over the rails, or from other causes.—Patent abandoned.

1781 J. EDWARDS. *Improvements in lifts or cages and tubs for raising minerals from pits or mines.* Dated June 18, 1867.

The patentee forms the frames of his cages of pipes jointed by angles and T's, as gas pipes are.—Patent completed.

1782 T. BROWN. *An improved apparatus for holding and lifting plates and dishes.* (A communication.) Dated June 18, 1867.

This apparatus is designed for the purpose of lifting heated plates and dishes, and consists of two parallel arms formed of wire, &c., which extend radially from a rod or handle, the extremities being formed to lie under the rim of a plate or dish and support the same. One of the arms is fixed rigidly upon the handle, while the other swings loosely thereon, and is arranged to open and allow the apparatus to be adjusted to articles of various sizes.—Patent abandoned.

1783 J. G. JONES. *Improvements in apparatus to be used for getting coal, stone, and other minerals.* Dated June 18, 1867.

This invention relates, first, to an arrangement of apparatus to be employed when driving headings in coal mines, and is applicable when machines are employed for cutting grooves into the coal to facilitate its removal. The special merit claimed is the laying in order of, first, longitudinal; second, transversed; third, longitudinal rails to carry any coal-cutting machine and facilitate its being moved out of the way. The second part of the invention relates to certain improvements in the hydraulic wedging-down apparatus.—Patent completed.

1784 W. S. THOMPSON. *Improvements in the construction of heating and annealing furnaces.* (A communication.) Dated June 18, 1867.

This invention cannot be satisfactorily described without drawings.—Patent abandoned.

1785 J. LANG. *Improvements in breech-loading firearms.* Dated June 18, 1867.

The first improvement relates to a new arrangement or construction of locking bolt for securing the barrel or barrels in place, and consists in the use of a horizontal spring bolt which is mounted on a vertical centre pin fixed in the body of the gun. When the barrels are brought down on their seat, a notched lump fixed on the under side of the barrels comes against and forces back the horizontal locking bolt, which turns on its centre pin to yield to the pressure of the notched lump, and then springs back into the notch.—Patent abandoned.

1786 D. JONES. *Improvements in the manufacture of coal vases, buckets, casks, and other similar articles of hollow ware.* Dated June 19, 1867.

This invention is not described apart from the drawings.—Patent completed.

1787 F. W. WAIDE. *An improved mode of obtaining motive power.* Dated June 19, 1867.

The inventor makes use of a closed fire-box, in which the coal or other fuel is burnt, the compressed air for supporting combustion being supplied from a blast engine or otherwise through a pipe furnished with a stop valve. The products of combustion from the fire-grate or stove are conveyed into a coil or series of pipes or flues placed within the boiler or chamber containing water, which is thereby heated and converted into steam. The upper end of the coil of pipes or flues is open into the steam space at the top of the boiler, consequently the products of combustion (or heated air under pressure) are discharged into, and become mixed with, the steam, and the mixed air and steam are taken from the top of the boiler and utilized for obtaining motive power.—Patent abandoned.

1788 L. SIMON. *A new or improved machine for bronzing.* Dated June 19, 1867.

This invention is not described apart from the drawings.—Patent completed.

1789 M. LYONS. *Improvements in making frames for looking glasses, pictures, and mouldings.* Dated June 19, 1867.

In performing this invention the inventor gilds moulded, blown, or cut glass inside with leaf gold, or any of the well-known processes, so as to resemble a gilt frame; or he silvers them or coats them inside with Dutch leaf metal, and fills them, if hollow, with any well-known composition, and then fits them on wooden frames, or unites them in any way to make frames or mouldings.—Patent abandoned.

1790 J. COPPARD. *Closing of doors, windows, and other such apertures with a spring, when necessary to close them by such means.* Dated June 19, 1867.

This invention consists in adapting a ring made of india-rubber or other elastic substance as a substitute for the ordinary spring used for the purposes mentioned in the title, which said springs may be either round, square, or flat; but the patentee prefers them flat.—Patent completed.

1791 E. W. HUGHES and T. H. HEAD. *Improvements in rotary engines and pumps.* Dated June 19, 1867.

The object of this invention is to produce a complete rotary engine which maintains the action and reaction always the same, and all the pressure that is employed therefore effective, the pressure of the power always acting continuously, according to the area of the piston, and the pressure employed. The inventors employ an annular cylinder in which rotates a piston (or pistons), and concentric with which also rotates a centrepiece. At any one part of the internal periphery of the cylinder a piece is either cast on or fitted in, touching the internal centrepiece, and forming a joint therewith. The piston (or pistons) on the turning of the machine retires into the centrepiece on coming to the cam on the internal periphery (in which are also the eduction and induction ports), and on passing such cam is forced out again, either by spring, or by the water, steam, or other pressure.—Patent abandoned.

1792 A. L. PANTER. *An improved seat for babies or young children.* Dated June 19, 1867.

In constructing this seat a circular base board is mounted on castors, the said base board supporting a cushion having a raised rim stuffed or padded, and passing about half round it and forming a low back. There is also a stuffed or padded projection which comes between the legs of the child, thereby preventing its slipping off at the front of the seat. Various straps are employed for securing the child in the seat, and a board may be fitted in the front of the seat for holding toys, &c.—Patent abandoned.

1793 H. C. HURRY. *Improvements in stop-blocks and buffer stops to be used upon railways, part of which improvements is also applicable to the working of points on railways.* Dated June 19, 1867.

According to this invention the stop block or buffer stop is made to turn round a horizontal axis situated in the centre of the web of the rail, or some other point in the vertical line of the section thereof, and this block or buffer may be connected to a disc or other signal in such a manner that the movement of the stop block around the axis in one direction shall cause the said disc to turn so as to show the flat side.—Patent completed.

1794 W. M'LELLAN. *Improvements in railway buffers.* Dated June 19, 1867.

This invention consists in so constructing the buffers as, with a given quantity of the vulcanized rubber used as the elastic medium, to obtain an increased range and improved action; and the features of novelty are, first, the making concave those sides or surfaces of the rubber rings or pieces which ordinarily become convex under compression; and, second, the making either concave or convex the sides or surfaces of the rubber rings or pieces on which the compression acts.—Patent abandoned.

1795 J. H. JOHNSON. *Improvements in the treatment of yarns intended to be printed.* (A communication.) Dated June 19, 1867.

This invention relates to a mode of treating yarns of silk, wool, cotton, and other fibrous materials intended to be printed, and consists in weaving such yarns into a temporary loose fabric by combining therewith warp threads of cotton or other suitable material, such warp threads being disposed, by preference, in pairs at wide intervals, the yarns to be printed forming the weft of the temporary fabric. Yarns so treated or woven into a temporary fabric may then be printed or otherwise treated with colouring matter while still forming the weft of such fabric. After having been printed or otherwise treated with colouring matter the weft of the temporary fabric is separated or divided into hanks or skeins, to facilitate which operation the warp threads are cut and drawn out. Each length or portion of the said temporary fabric forming a hank or skein may be pushed on to a pair of wooden or metal rods or pins, such rods or pins being passed into the bends or loops of the yarn formed over the selvage cord, which may be either single or double, and the next inner cord or thread of the warp, which thread, for the sake of distinction, is termed the loop thread.—Patent completed.

1796 J. E. WHITING. *Improvements in the construction of castors.* Dated June 19, 1867.

The object of this invention is to arrange the castor so that the weight of the article of furniture may be placed centrally over the roller. The supporting roller turns on a pin placed immediately beneath the centre of the castor, and a guide wheel or fixed guiding point, stud, or spring is adapted to the extremity of the horn, so as to guide and turn the castor round on its vertical spindle when required.—Patent abandoned.

1797 D. JONES. *Improvements in the manufacture of bails or handles for articles or vessels of hollow ware.* Dated June 20, 1867.

This invention consists in forming the bails or handles of articles of hollow ware in such a manner that a substantial bulk or swell is produced for the grasp of the hand. This may be effected in one way by cutting out a pair of blanks to an outline which when stamped in a suitable die or press will form the two halves of a curved swell or handle; a piece of rod iron or wire of suitable length and thickness to form the bail is then placed between or passed through the two stamped halves of the handle or swell, the ends of which are of such size and stamped so as to fit the circumference of the rod or wire. A small washer passing over each of these ends is held in position by turning up the edges of the swell or handle, or by soldering the parts.—Patent completed.

1798 A. M. CLARK. *Improvements in apparatus for sewing saddlery and other leather or strong materials.* (A communication.) Dated June 20, 1867.

In this improved apparatus two needles are employed, the one serving as an awl, the other carrying the thread; the two needles have at the same time a vertical movement, and also an adjustable horizontal movement, the needles are operated alternately. Second, the invention relates to improvements in the arrangement of the shuttle whereby it is caused to pass through the hoops formed by the waxed thread without touching it.—Patent completed.

1799 T. WILSON. *Improvements in movable spanners or screw wrenches.* Dated June 20, 1867.

This invention consists, first, actuating and adjusting the slide bar or movable jaw by means of a conical worm or screw attached to the end of the handle of the spanner or screw wrench, engaging with a rack or screw teeth formed upon the edge of the slide bar or movable jaw of the said spanner or wrench. By giving a rotary motion to the handle, the slide bar or movable jaw may be made to approach to or to recede from the fixed jaw. The invention consists, further, in actuating and adjusting the slide bar or movable jaw of spanners or screw wrenches by means of a small pinion engaging in the teeth of a rack upon the edge of the slide bar.—Patent abandoned.

1800 F. G. N. PERRETT. *The self-regulating balance blind pulley.* Dated June 20, 1867.

In performing this invention the patentee passes a cord over the wheel or sheave of the curtains or roller blinds in the ordinary way, and then passes the same under a wheel, roller, or sheave fixed at the upper end of a balance weight of any required shape or size enclosed in an outer case of metal, this outer casing being made open at both ends, so that the weight can work up or down through the same, and by its weight alone retain the curtain or roller blind cords at one uniform tension.—Patent completed.

Digitized by Google

1801 L. STERNE. *Improvements in chucks or apparatus for holding drills or boring tools.* (A communication.) Dated June 20, 1867.

This invention consists in the employment of a pair of spring jaws, each half of which is preferably composed of a spring plate seemed at one end, while its other end carries a block of metal or other material forming the jaw proper. The acting face of each block is recessed, the two recesses forming a tapered hole, the narrow parts of which is at the exterior. The invention further consists in combining with the spring jaws a shank held between the spring places, and having at the end adjoining the blocks a tapered socket or recess. The drill or tool is placed with its back end in this socket, and nuts acting on screws passed through the blocks are then screwed up, so that the tool is not only central, and held at its back end, but is also held about midway of its length by the jaws. The tapered socket will adapt itself to different sized drills.—Patent abandoned.

1802 C. STUART. *An improved arrangement or construction of adjustable wrenches.* Dated June 20, 1867.

The object of the first part of this invention is the arrangement and construction of an adjustable wrench in which the retaining power consists of a liquid, either water, oil, or other suitable substance. The second part of the invention relates to a different arrangement of adjustable wrench.—Patent abandoned.

1803 H. K. YORK. *Improvements in the manufacture of steel.* Dated June 20, 1867.

This invention consists in manufacturing steel from cast iron by fusing a mixture composed of iron purified and decarbonized according to the process described in the specification of a previous patent granted to the present patentee dated 5th May, 1866 (No. 1,291), and a certain proportion of cast iron containing carbon, or carbon and manganese, which is commonly known as spiegeleisen.—Patent completed.

1804 H. G. B. ROBER. *Improvements in the construction of safety-box slides.* Dated June 20, 1867.

Into the top or other part of the box there is filled a trunk or passage. On two opposite sides of the passage centres or studs are fixed on which two arms are able to turn. At their upper ends these arms carry a cover for the top of the passage, and the cover has a knob upon it by which it can be moved about its centres, so as to uncover the passage when required, but, when the knob is released, a counterbalance weight brings the cover back over the passage. Formed with these parts, and turning the same centres, are other arms carrying a cover for the lower end of the passage, and this is so placed as to close the bottom of the passage when its upper end is uncovered.—Patent completed.

1805 J. WARD and F. DRESSLER. *Improvements in easy or invalid chairs.* Dated June 20, 1867.

The patentee claims combining the back and seat of a chair, and both, with the frame in the manner described. Also locking the back and seat in position by a toothed or notched arc jointed at the back to the frame, and catching on to a bar forming the joints between the arms on the back and the links which support the back of the seat. Also combining with chairs having adjustable seats and backs a jointed foot-rest connected to the seat with tangs or stems and sockets capable of being worked by set screws at any desired inclination to the seat.—Patent completed.

1806 J. W. COCHRAN. *Improvements in projectiles and cartridges for ordnance and firearms.* Dated June 20, 1867.

This invention consists, first, in forming the exterior of a hollow projectile or shell of a metal tube of equal thickness on all sides; second, in the employment of rings formed with lateral teeth or corrugations, and fitted or packed closely together within the outer case or tube, which rings break and scatter when the shell explodes. Third, in the employment of a central fixed tube to keep the wings in place. Fourth, in the arrangement of an inner tube or case containing the charge, which tube slides forward and explodes the percussion fuze when the projectile strikes an object. Fifth, in the combination with the said sliding tube of a percussion fuze consisting of a nipple attached to the said tube. Sixth, in the novel construction of a time fuze.—Patent abandoned.

1807 W. CLARKE. *Improvements in the production of ornamental fabrics.* Dated June 20, 1867.

This invention is not described apart from the drawings.—Patent completed.

1808 J. W. PERKINS. *Improvements in stills for petroleum paraffine oil, tar, turpentine, and like bodies.* Dated June 21 1867.

This still consists of a series of chambers or compartments in communication with each other, each of which chambers contains a coil of pipes, through which the heating medium is caused to flow.—Patent abandoned.

1809 W. ROBERTSON and C. J. WADDELL. *Improvements in the apparatus by which the oscillations of the comb in the carding engine, the knife in the cotton gin, and the saw in the reaping machine, or reciprocating saw, may be readily multiplied.* Dated June 21, 1867.

According to this invention the inventors employ as the instrument of multiplication a knee joint having three axes, two external and one central. Of the external, one is a fixed stud; the other is a stud fastened in the part the oscillations of which are to be multiplied. The central axis is moved equally on each side of the line joining the three axes when the joint is unbent, and the external axes are thereby made to approach and recede from each other twice for each oscillation. In employing more than one multiplication the second external axis is a stud in one of the legs of the second multiplying joint.—Patent abandoned.

1811 B. BROWNE. *Improvements in the construction of camp or folding bedsteads.* (A communication.) Dated June 21, 1867.

The sides of this bedstead are formed of round pieces of wood in three parts, hinged together by metal hinges so as to fold up; around these side pieces the sacking is fixed. The hinges are each formed of two pieces of cast iron, and into one piece a flat piece of metal is fixed, and has a slot therein through which passes a pin, the pin being fixed across one end of a short tube of metal, the other end of the tube having a round piece of wood fixed thereunto; and in this manner each hinged piece is provided, these pieces of wood being used as the legs of the bedstead, and also to keep the sacking distended. To effect this the inventor crosses the legs like the letter X, and around each of the crossing parts is fixed a short tube of metal, in one of which, and midway of its length, is fixed a T-shaped piece of metal, which takes and locks into a corresponding shaped recess formed in the tube which is upon the other leg, and the legs are thus held together. The legs at the head part of the bedstead are longer than the other legs, for making the sacking higher at this part of the bedstead, so as to serve as a pillow.—Patent abandoned.

1812 J. GARDNER. *Improvements in the construction of folding bedsteads and couches.* Dated June 21, 1867.

The side supports of this bedstead each consist of two ribs jointed to each other at one end, the joint being at or near the middle of the bedstead, and of such form that the ribs will fold upon one another, or nearly so, but will not open out to a greater extent than to form an angle of about 120deg. more or less, with each other. Transverse strengthening pieces connect the side supports. To the outer ends of the ribs at each side are jointed the head and foot rails, the joints allowing these rails to fold upon the transverse strengthening pieces. Near the inner ends of the ribs, at each side, the inventor hinges two stretchers, one for each half of the bedstead, and the hoop iron bands forming the support for the bed are riveted to the sides and ends of the stretchers. The outer ends of the stretchers carry hooks, &c., to take hold of the transverse bars, so that the two stretchers and the head and foot rails may mutually support each other when in position, and at any desired angle. To strengthen the side supports, a hinge is fitted a little below the hinge before described, which hinge, when the bedstead is folded, falls down and allows the ribs to fall nearly upon each other.—Patent abandoned.

1813 J. POWIS and J. S. JAMES. *Improvements in tenon cutting machines.* Dated June 21, 1867.

This invention consists in using three horizontal spindles with blocks and cutters for cutting double tenons, the wood being fed to the cutters in the ordinary manner. The spindles are preferred to be in the same vertical line. An arrangement of table with three slides is also described to be used with the machine.—Patent abandoned.

1814 W. BELLHOUSE. *Improvements in furnaces for consuming smoke, applicable to steam boilers and other furnaces.* Dated June 21, 1867.

Here the inventor forms an additional bridge behind the furnace bars, so as to form an air chamber, which is covered with a grid, the level of the grid being higher than that of the furnace bars. At the rear of the additional bridge a hole is made to receive a pipe which is carried to the rear of the boiler, and extended vertically to a funnel-shaped inlet. The products of combustion in passing through the flue are thus carried over the grid, where they are met by a supply of air which is heated in its passage through the pipe by the heat of the furnace, the smoke and gases being mingled with the air and consumed.—Patent abandoned.

1815 A. M. CLARK. *Improvements in apparatus for measuring horses' feet, and for adapting and fitting shoes thereto.* (A communication.) Dated June 21, 1867.

This invention is not described apart from the drawings.—Patent completed.

1816 F. C. HENNET and D. SPINK. *Improvements applicable to apparatus for raising and lowering weights, for indicating and registering the amount lifted, or for indicating only the said weight.* Dated June 21, 1867.

The crane or other chain for lifting is passed through a block which is connected by rods to a weighted lever, the deflection of which shows the amount of weight being lifted, the lever having an index or dial, and a needle or hand, to indicate the deflection on the divisions of such dial which show the weight. For registering as well as indicating the weight, a second hand is applied on the dial, actuated by the one first mentioned, which remains stationary on being moved to any point in order to register the weight.—Patent abandoned.

1817 B. and T. FORD. *Improvements in water tuyeres.* Dated June 21, 1867.

This invention consists in providing a tank in connection with the tuyere, the tuyere being so attached to the tank that both its ends are inserted through the sides of the tank, which, being kept supplied with water, and the tuyere being so attached that the water may flow freely therein, the tubes of the tuyere are kept full of the liquid. Ordinarily, when the nose of the tuyere gets so hot as to cause the water therein to boil, steam is generated, and there is danger of the tuyere exploding; or if this does not happen, it becomes so damaged from the fire as to be afterwards useless. By these improvements, although the water may be caused temporarily to boil at the nose of the tuyere, the flow of water coming from the tank will be sufficient to force a fresh supply of cold fluid to the nose, and to all the other parts of the tuyere exposed to great heat, and so all danger of explosion is avoided.—Patent abandoned.

1818 W. PRICE. *Improvements in the manufacture of dies for stamping.* Dated June 21, 1867.

This invention consists in casting the whole of the die in cast steel from a mould.—Patent abandoned.

1819 G. DICKIE. *Improvements in the manufacture of illuminating gas.* Dated June 21, 1867.

In obtaining illuminating gas from oils of the mineral hydrocarbon class, the oil or oils is or are admitted into a highly heated retort, &c., the temperature of which at once causes the conversion of the oil into a permanent gas of high illuminating power.—Patent completed.

1820 G. SIMPSON. *Improvements in charging and emptying retorts, and in the machinery or apparatus employed therefor.* Dated June 21, 1867.

Here the range of retorts is built in the ordinary manner, and a frame is made for each retort that fits into and rests upon its bottom. Each frame has a set of trays, which trays are hinged to the frame at one side, the trays being used for containing the material with which the retort is to be charged. In front of this retort one or more travelling frames is or are situated, any one of which may, at any time, be moved to any one retort of the series; its upper side is level with the bottom of the retorts, so that the frame and trays may be drawn out from the retort; as the trays pass over a plate at its back end, they fall over on the hinge joints and discharge their contents, and on being again put into the retort, the trays, as they pass over the plate before referred to, are thereby again lifted to their horizontal position, in which position, as they pass into the retort, they are discharged by means of a belt of elevators, which discharge a certain quantity of the substance to be distilled into each tray; when the frames and trays are passed into the retort, its mouth is closed, and the distilling process is carried on in the ordinary manner. The frame and trays are drawn in and out by chain gearing, and this and the elevator are actuated by a steam engine or other prime mover.—Patent abandoned.

1821 F. REDDICLIFFE. *Improvements in buckets for pumps, especially suitable for pumps for mines, and in pistons for steam and other engines.* Dated June 21, 1867.

This invention consists of certain mechanical arrangements whereby the patentee adjusts the packing of the pistons of steam or motive power engines or pump buckets as the same wears away. He places two plates or rings of metal one above the other, and connects them together by distance pieces. Upon the faces of these plates, which stand toward each other, are protuberances, so disposed that they do not stand opposite each other, but in directions between one another, and each extends for half the space between the two plates. The packing pieces or gearing are introduced into the apertures between the protuberances; they are made to fit water-tight, and to overlap each other at the ends. Each packing piece carries an arm projecting inwards, and furnished with a ruck. These rucks are so disposed as to receive a pinion between them, whereby the packing may be adjusted as it wears. The pinion carries a fork, and when the packing is to be adjusted, the rods are disengaged from the engine at the top of the pump, and the bucket lowered on a bar near the bottom of the working barrel. The fork crossing the bar will keep the pinion in position, and the bucket being turned by the rods will be equivalent to turning the pinion, and the packing or gearing will thus be adjusted. The bucket can then be drawn up clear of the bar and set to work.—Patent completed.

1822 E. M'CLINTOCK. *Improvements in the construction of motive power engines and pumps.* Dated June 21, 1867.

Here the patentee employs a double-acting cylinder and piston, serving also respectively as valve box and valve, in combination with one other similar cylinder with its piston. The two cylinders and their pistons are so arranged that the piston of each cylinder shall act as a valve to govern the distribution of steam, or other fluid or liquid, for the other cylinder.—Patent completed.

1823 J. ONSLOW and F. NORTHALL. *Certain improvements in the construction of water tuyeres.* Dated June 22, 1867.

This water tuyere is so formed that the water way is divided into two parts of equal proportions. The division is effected by placing inside the water way two metal partitions opposite to each other, and which fit up to the back part of the tuyere, reaching to within about three inches of the nose or front part of the tuyere. This arrangement compels the water contained in the tuyere to pass freely round its nose, the partitions serving as channels for the water. The outlet pipe of the tuyere is of slightly smaller diameter than its inlet pipe.—Patent abandoned.

1824 O. R. CHASE. *An improved combined feed water regulator and water gauge for steam boilers.* (A communication.) Dated June 22, 1867.

This invention relates to an apparatus for preventing injurious variations in the level of the water in steam boilers, and consists, chiefly, in the use of devices operated by a float to open and close the stop valve of the feed pump, or otherwise control the supply of water to the boiler. Two sliding blocks are connected to levers which operate the stop valve, and the float in rising or falling elevates or depresses a cam and guide, whereby a vibrating link is caused to take hold of one or other of the said blocks, and thereby operate the corresponding regulating lever to admit or cut off the supply of water to the boiler. The invention also consists in the combination of a scale and pointer with the regulating mechanism, which pointer follows the movements of the float, and is caused (by the devices which operate the vibrating link) to oscillate over the face of the scale, and indicate thereon the height and variation of the level of the water.—Patent completed.

1825 R. W. MORRELL. *Improvements in dyeing black upon certain mixed textile fabrics made of worsted, alpaca, or mohair, woven in combination with cotton.* Dated June 22, 1867.

The patentee claims, firstly, the dyeing of the materials above named, either in the warp or weft, or both, with the wood and indigo process (separately, or in combination) in addition to the ordinary process of dyeing to ensure a faster and more intense colour as a black than the ordinary methods of dyeing will effect, as described. Second, the dyeing of "pieces," as described, having white or undyed cotton warp or weft, with woad or indigo (separately, or in combination) in addition to the ordinary process, in order to obtain a more intense black on the cotton portion of the fabric, and for dispensing with the use of oil or glycerine for bringing up the colour upon the cotton portion of the fabric.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated September 19, 1867.

2630 T. C. Clarkson, Stamford-street, Blackfriars-road, manufacturer. Improvements in the method of and materials for manufacturing ammunition boxes, pontoons, baggage, and other waggons and carriages and various equipments for military, naval, and civil purposes.

Dated November 28, 1867.

3381 E. H. Bentall, Heybridge, near Maldon, agricultural implement manufacturer. Improvements in the manufacture of nuts and bolts.

Dated December 11, 1867.

3520 F. Vita, Rue Feydeau, Paris, merchant. A new or improved material to be employed in the manufacture of cord, rope, lace, paper, cardboard, pasteboard, and other articles.

Dated December 18, 1867.

3600 J. Cockshoot, jun., Manchester. Certain improvements in the construction of carriages, landaus, and other similar vehicles.

Dated December 24, 1867.

3658 P. Demeure, Rue Croix Nivers (Grenelle), Paris, mechanician. An improved railway carriage break.

Dated December 27, 1867.

3682 J. W. Lewis, Newcastle-upon-Tyne, engineer. Improvements in warming, ventilating, and heating apartments or buildings, and in the arrangement of apparatus connected therewith.

Digitized by Google

Dated December 30, 1867.

3704 A. M. Clark, Chancery-lane. Improvements in the permanent way of railways. (A communication.)

3705 A. Grainger, Lower Kennington-lane, Surrey, surveyor. Improvements in the construction of roads or carriage-ways and footpaths.

Dated December 31, 1867.

3721 R. Tooth, Fenchurch-street, City. An improved mode of and apparatus for evaporating liquids, with a view to obtaining the saccharine, saline, or other substances contained therein, in a dry or crystalline state.

Dated January 1, 1868.

4 G. A. D. Goodyar, Osborne Villas, Windsor. Improvements in the method of and machinery for propelling boats or vessels.

12 C. W. May, Rue Gaillon, Paris, manufacturer. Improvements in the manufacture of metallic cartridges.

Dated January 3, 1868.

22 J. S. Cockings, civil engineer, and F. Potts, manager of works, Birmingham. Certain improvements in welded iron tubes for gas, and other purposes where strength and lightness are required.

Dated January 6, 1868.

38 G. Platts, Stockport, W. Tate, agents, and W. H. Bailey, Salford, brass founder. An improved mode or method of and apparatus for laying fog signals on railways.

40 E. Gourdin, Boulevard of Sebastopol, Paris, merchant. Improvements in the modes or methods of combining a lamp or lighting appliance with a cane or walking stick.

43 J. Combe, Belfast. Improvements in machinery for winding or balling yarn or other twisted material.

45 J. Gardner, South Bridge, Edinburgh, surgical instrument maker. Projecting liquids in the form of spray by a draft or current of air forced through part of the liquid, and an instrument or apparatus for such purpose.

Dated January 7, 1868.

46 F. W. Hartley, Millbank-street, Westminster, gas engineer. Improvements in optical illusions used in conjunction with the magic lantern.

47 E. Myers, Craven-street, Strand, and G. A. Cannot, Pudding-lane, City. Improvements in the permanent way of railways.

48 C. D. Abel, Southampton-buildings, Chancery-lane. An improved method or process for removing sulphur, phosphorus, and other impurities, from iron, steel, and other metals. (A communication.)

52 J. Maury, Liverpool. Improvements in connecting the ends of metallic straps applied to bales of cotton and other merchandize.

54 J. Granville, Liverpool. Improvements applicable to lowering boats from ships' sides in a seaway.

56 J. B. Dunn, Castle-street, Liverpool. An improved buckle or tie for connecting the ends of metallic straps applied to bales of cotton and other merchandize.

58 W. Avery, Redditch, needle manufacturer. Improvements in the manufacture of needle cases.

60 G. Warsop, Mount-street, Nottingham. Improvements in mangles.

62 G. Warsop, Mount-street, Nottingham. Improvements in washing machines.

64 P. Spence, Newton Heath, Manchester, chemist. Improvements applicable to roasting or calcining copper and other ores containing sulphur and also regulus, and in apparatus connected therewith.

Dated January 8, 1868.

66 M. Grant, St. Paul's-road, Camden-road. Improved playing cards for the use of short-sighted and aged persons, as well as for persons of good vision.

67 J. Tomlinson, Rochdale, machine maker. Improvements in machinery for twisting and untwisting flax, hemp, and other fibrous substances.

69 S. Goldstein, Manchester, merchant. Improvements in that portion of gentleman's attire called the vest or waistcoat.

70 M. Walker, Essex-street, Strand, engineer, and G. H. Money, Jermyn-street, Middlesex, Lieut.-Colonel. Improvements in breech-loading small arms, including pistols, and in the cartridges to be used therewith.

72 C. Pontifex, Northampton-grove, Ball's Pond, vat maker. Improvements in presses or apparatus for expressing wort from spent hops, the same being applicable for expressing fluids from other matters.

74 G. W. Bacon, Strand, publisher. Improvements in apparatus for gymnastic purposes.

75 R. Girdwood, Edinburgh. Improvements in bags for transmitting samples or materials by post or otherwise.

76 J. Dawson and J. Howorth, Bacup, Lancashire. Certain improvements in looms for weaving.

77 S. Benjamin, Lancaster-road, Bayswater, merchant. Improvements in receptacles for coin or other valuable articles. (A communication.)

78 W. E. Kenworthy, Crown Point-road, Leeds, agricultural chemist and oil merchant. An improved method of purifying drains and sewers.

79 W. E. Newton, Chancery-lane, civil engineer. An improved mode of propelling vessels. (A communication.)

80 T. Greenwood, Leeds, machine maker. Improvements in machinery for preparing to be spun silk, china grass, and other similar fibrous substances. (A communication.)

81 J. Petrie, jun., Rochdale, machine maker. Improvements in brats or travelling surfaces for conveying wool and other fibrous materials out of or into washing machines, which improvements are also applicable to other machines in which similar travelling surfaces are required.

83 J. Tucker, Old Lenton, Nottingham, starch manufacturer. Improvements in the manufacture of paper.

84 W. R. Lake, Southampton-buildings, Chancery-lane, consulting engineer. Improvements in cutters for forming wood mouldings, and for other like purposes. (A communication.)

Dated January 9, 1868.

85 C. J. B. King, Great Portland-street. An improved process to be employed in the tanning of skins or hides.

86 C. H. Newman, Temperance Brewery, Brentford End. Improvements in the manufacture of unfermented and unintoxicating malt liquors.

88 G. A. Heath, Greenwich, carpenter. Improvements in sash fastenings.

Dated January 10, 1868.

91 J. Vivez, Quai Jemmapes, Paris, lamp manufacturer. Improvements in the construction of lamps for burning volatile hydrocarbons and other mineral essences or compounds.

92 J. Lewtas, Manchester, window blind manufacturer. Improved apparatus for holding and releasing the cords of venetian and other blinds.

94 S. Mortimer, Bradford, machine and tool maker. Improvements in machinery for combing wool or other fibrous substances.

95 J. Fawcett, Kirton, Lindsey, cake manufacturer. An improved manufacture of cattle food.

96 J. M. Rowan, Glasgow, engineer. Improvements in the manufacture of artificial fuel. (A communication.)

97 G. Davies, Serle-street, Lincoln's Inn. An improved self-supplying pen. (A communication.)

98 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in apparatus for sewing the backs of books for the purpose of binding the series of numbers or separate sections of a book or volume together. (A communication.)

Dated January 11, 1868.

99 H. Cochrane, The Longlands, Middlesborough-on-Tees. Improvements in machinery or apparatus for making moulds for hollow and other castings, and for testing or proving hollow castings.

100 W. Champness, Manchester. Improvements in the method of ornamenting wearing apparel, turned stays, and corsets, or riding belts.

101 C. S. Lemon, Liverpool, ship owner. Improvements in shirt fronts and other similar garments.

102 A. Budenberg, Manchester. Improvements in steam hammers. (A communication.)

103 J. Pilling, machinist, and R. Scaife, overlooker, Colne, Lancashire. Certain improvements in machinery or apparatus to be employed in spinning, twisting, or doubling cotton, silk, or other fibrous substances.

104 J. Hirst, machinist, and W. Hirst, clog and patten maker, Halifax. Improved machinery to be employed in the manufacture of clog soles and patten boards.

105 J. Somervell, Kendal. An improved method of obtaining and preserving alimentary substances in a highly concentrated form.

106 W. W. Hooper, Bow, optician. Improvements in apparatus for giving signals on board ship or other places.

107 J. C. Ellison, Rawfolds, Yorkshire, dyer. Improvements in machinery for folding fabrics, and also for inserting papers, metallic plates, or other suitable substances, between the folds of fabrics for pressing.

108 N. Hodgson, New Barnet, machinist. Improvements in engines to be worked by water pressure, compressed air, or other elastic fluid.

109 J. G. Tongue, Southampton-buildings, Chancery-lane. Improvements in machinery or apparatus for sizing the backs of carpets or other pile fabrics. (A communication.)

111 J. H. Johnson, Lincoln's Inn-fields. Improvements in pipes for smoking. (A communication.)

112 T. Whitwell, Stockton-on-Tees, iron master. Improvements in furnaces.

113 G. Ireland, Handsworth, Staffordshire, manager of works. Improvements in cruet frames, liquor frames, and other frames for holding bottles and vessels and other articles.

114 T. S. Ellin, Sheffield. An improved self-securing skate. (A communication.)

Dated January 13, 1868.

115 M. A. Hamilton, Southampton-buildings, Chancery-lane. An improved device for holding pens, pencils, papers, and other articles.

116 P. Pittar, Gresham-street, City. Improvements in mineral and rock drilling apparatus.

117 J. M. Kirby, Northampton. Improvements in the means of and apparatus for generating steam and warming buildings.

Dated January 14, 1868.

121 W. E. Gedge, Wellington-street, Strand. Improvements in the construction of breech-loading firearms. (A communication.)

123 C. W. Lewis, Langham-place, merchant. An improved spirit level. (A communication.)

125 J. C. Ramsden, Bradford, reed maker. Improvements in the mechanism or apparatus of looms for producing a certain class of fancy fabrics.

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated January 18, 1868.

174 H. H. Lloyd, Fort William, Douglas, Isle of Man, Colonel. Improvements in coffins.

179 H. A. Bonneville, Sackville-street, Piccadilly. A new and improved fly cover for protecting stitched books. (A communication.)

Dated January 20, 1868.

197 W. R. Lake, Southampton-buildings, Chancery-lane, consulting engineer. Improvements in wood rings or washers, and in machinery for manufacturing the same. (A communication.)

198 W. R. Lake, Southampton-buildings, Chancery-lane, consulting engineer. Improvements in machinery for nailing or pegging the soles of boots and shoes to their vamps or uppers. (A communication.)

Dated January 21, 1868.

211 T. V. Lee, Macclesfield, civil engineer. Improvements in producing charcoal fuel and fire-lights from peat, and for kilns and machinery to be employed therein.

LIST OF SEALED PATENTS.

Sealed January 24, 1868.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," January 28, 1868.

2609 G. F. Bradbury and T. Chadwick. Sewing machines.
2610 W. J. Cunningham. Sewing machines.
2620 T. Stevenson. Faggots.
2621 A. M. Clark. Valve closets. (A communication.)
2627 T. B. Wilkinson. Apparatus for crushing beans.
2630 T. C. Clarkson. Ammunition boxes.
2632 J. Rust. Material for decorative purposes.
2637 J. G. Willans. Iron.
2639 J. H. Sams. Drill sowing machines.
2652 W. Hall. Separating yeast from liquid matters.
2653 W. E. Newton. Whips. (A communication.)
2654 C. E. and J. Green. Cartridges.
2656 G. E. Marchisio. Treatment of the residuum of cotton seed.
2657 J. Hargreaves. Iron.
2665 A. Mackenzie and S. Robinson. Cisterns.
2667 T. Muir. Washing rollers.
2669 J. Rives. Metallic pens.
2673 G. W. M'George. Pipes for smoking.
2677 W. Cooke. Regulation of currents of air in shafts.
2693 R. Wilson and J. Nuttall. Cranked axles.
2699 A. Tod and J. Heatley. Manufacture of tobacco.
2708 G. H. J. Simmons. Lamps.
2756 E. P. Alexander. Cast steel. (A communication.)
2761 J. L. Field. Candles and moulds.
2788 G. Mellor. Nails.
2811 N. F. Taylor. Impregnating air with hydrocarbons.
2865 W. E. Newton. Preparing iron. (A communication.)
2992 J. Mitchell. Buffers.
3013 R. Carter. Looms for weaving.
3042 E. B. Wilson. Furnaces.
3284 H. H. Lloyd. Signals.
3291 L. B. Joseph. Tramways.
3441 R. Hornsby and J. E. Phillips. Reaping machines.
3530 N. Paxman. Steam cylinders.
3600 J. Cockshoot, jun. Carriages and landaus.
3712 J. Novikow. Drawing and spinning hemp.
76 J. Dawson and J. Howorth. Looms for weaving.
80 T. Greenwood. Preparing silk. (A communication.)
103 J. Pilling and R. Scaife. Spinning cotton.
179 H. A. Bonneville. Fly cover for protecting books. (A communication.)
197 W. R. Lake. Wood rings or washers. (A communication.)
198 W. R. Lake. Nailing the soles of boots to their vamps. (A communication.)

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, FEBRUARY 7, 1868.

TECHNICAL EDUCATION.

IT may safely be predicted that the present time is pre-eminently one of educational manifestoes. How far the speeches and debates at Manchester and in London will really forward a movement of vital importance to the nation remains to be proved; but when a subject of real importance is openly discussed by capable men it never loses by its publicity, though not a few of the views put forward may be erroneous, and the selection of the speakers altogether arbitrary, as in the case of the Society of Arts meeting. We confess ourselves disappointed with the scope of the resolutions proposed and carried—by no means unanimously—at that conference. Framed prior to a discussion which time rendered altogether inadequate, they cannot be taken as a deliberate digest of the majority of opinion of a concourse of minds really competent to take cognizance of such a subject if free discussion had been allowed. The pre-determined idea was that nothing but general, *i.e.*, loose resolutions, should be passed, and the result arrived at was the enunciation of the fact that extended education in England was desirable, which everybody knew beforehand. It is the great lesson which thinking men have tried to teach us for more than a century, and which intercourse—and, above all, competition with more generally educated nations—has brought practically and tangibly before us in the last twenty years. The question propounded for the Society of Arts discussion was that of "Technical Education." That really discussed there, was education at large, descending, if at all, into the distinction between a classical and scientific, or, as some would have it, artistic basis of instruction. Now, in the phase of the subject with which we have to deal, such a question is easily dismissed on two manifest grounds, first, because with the main body of the working classes in this or any other country there is not time to spare for anything but rudimetary teaching, properly so called. Education—that is, the training of the mind after rudimentary instruction for the reception of really elevated ideas—is impossible from economic considerations to the great mass of those who must earn their bread from day to day, though it may succeed well if conducted by a course of either classical or scientific study, treated as study in the abstract, for the purpose of training only. Secondly, because whatever may be the merits of that tendency of thought induced by classical study for some sections of the world's workers and thinkers, there is no merit, but an actual demerit, in such a groundwork for those who are to deal with matter not with man, who investigate and apply the latent forces of nature instead of either combating the follies or developing the resources of human intellect.

What is wanting for the elevation of that large and important class of Englishmen with whom in this discussion we are principally concerned, is, first, rudimentary instruction for the very young, not only free and universal, but, within certain limits and restrictions, to bring it within our English ideas of liberty. Compulsory, and, secondly, such a system of scientific education freely open as shall hold out to all that have the capacity a fair opportunity of obtaining that higher cultivation of which so many of the artizan class are worthy and so few of them can now practically obtain. Thus far we shall only be fitting two classes of the community for their appropriate work, the lower for a fairly intelligent prosecution of handicraft, the higher for a more extended appreciation of first principles, from the study and development of which, by a vastly increased number of individuals, the nation will incalculably benefit. Beyond and above these we require an endowed foundation for the few whose talent, industry, and ambition may raise them above mere training and education, and fit them for the real advancement of science as individual thinking beings.

Such are the requirements of the nation considered both internally and individually for its own positive development, and as compared with the advances made by other nations and the facilities afforded in their actual educational status, by comparison with which we now find ourselves, after thirty years' discussion and some Government action, very much behindhand. It is not our province to discuss the means by which politically it may be possible to obtain such results as are absolutely necessary to place Englishmen on a fair footing in this respect with the people of other States. The end may be accomplished, as a *pis-aller*, by Mr. Ayrton's confiscation of existing endowments, though why we should rob one class for the intellectual benefit of another it is difficult to see; or it may be brought about by a special organization, paid for by the nation at large, for the benefit of classes unable or unwilling to benefit themselves; but one way or other it must be brought about if we would even hold our own in the keen competition of modern intelligence. One thing, however, is certain, that the funds, from whatever source they come, must not be left at the mercy of the parochial boards, whose inefficiency in the discharge of their present duties is one of our most crying evils, or put up to be wrangled for by sectarian demagogues, nor, above all things, must they be in any way under the direction of that worthily-artistic, but utterly unscientific, department which occupies so prominent a position in the West End. Let us have no half measures after the long probation of years, in which successive Governments have talked much of education and effected little teaching, but let us have such a comprehensive scheme as shall at least embody the advantages obtainable by the citizens of many minor European states, though to this day unknown in England. Amongst the speakers in the short debate at the Society of Arts was one who put forward, as one of themselves, the views of the working classes, urging strenuously the institution of museums of art, or, as he called them, "South Kensingtons" in the midst of the centres of manufacturing industry. He spoke feelingly of the advantage to be derived both by the present and the rising generations from the possibility of studying at leisure the works of art, now visible only to a favoured few of his class. Perhaps no more effectual instrument for the development of a real taste for knowledge could be found than such exhibitions, if multiplied to such an extent, and in such positions as would render them commonly accessible to the class who would most benefit by them, and, if made, really of use in the great fields of science, instead of being confined to the subordinate subjects of art. However unfitted the South Kensington officials may be to take charge of an organized national education, there can be no doubt of the ameliorating influence of the art display, for which we are indebted to that national institution. No practical action in the matter of education can be hoped for till late in the coming Session, and we fear that any real settlement of the subject will be still further postponed, but we cannot avoid strenuously urging on those in whose power it is to do or not to do that every month, not to say year, frittered away in paltry discussion over the details of a great question, is a tangible intrinsic loss to the country and a cumulative loss also, for the more the gap widens between the bare possibility of improvement to our own youth, and the State obligation to improvement in most other civilized nations, the more will increase the difficulty of regaining the lost vantage ground which natural resources and national aptitude have hitherto given us in most industrial pursuits.

IMPERFECTIONS IN PHOTOGRAPHIC APPARATUS.

IN many respects photographic apparatus has not been brought to the highest attainable level of perfection, and our intention is now to point out to those manufacturers of apparatus who are on the alert to meet commercial demands before their competitors, some points where improvement is necessary. One of the most useful instruments, both to professional and amateur photographers, is the binocular box camera, enabling two cartes de visite to be taken on one plate, because it may also be used for stereoscopic pictures, or for landscapes when the central diaphragm is removed. Moreover, being a box camera, furnished with several dark slides, the whole packing up like a little portmanteau, it is very useful in travelling, or for taking outdoor views. Hence, cameras of this description are made and sold in large quantities, and competition and experience enable English manufacturers to turn them out beautifully made, the workmanship being unequalled on the Continent, and the admiration of photographers in the United States. Yet most of these cameras, and we believe all those at present in the market, have one great fault when they are required for outdoor work. Their several parts waste so much time in the operation of screwing together to take a view. Scarcely any of them have room in the box to carry the lenses attached to the front of the camera, so that valuable lenses have to be carried in the pocket at the risk of breakage in walking, and in the operations of screwing and unscrewing before and after taking each picture. These screwing operations involve waste of time; moreover, the camera usually has to be screwed upon the top of the box, then the back of the camera has to be pulled out and fixed down by two screws, and three or four screws are called into operation in fixing the legs. When the view is taken, the unscrewing work and packing away of the different parts begin. Supposing these operations to waste five or eight minutes over each view, the loss of time over the exposure of six or twelve plates is very great, and to this the annoyance of the unnecessary trouble must be added.

A very little forethought and ingenuity on the part of the manufacturer would enable him to do away with these real practical evils. The upper portion of the inside of the box, for instance, might be made to form the top and two sides of the camera, so that on opening a door at one end of the box, the lenses always in their right position would be pointing at the view, and on opening the other end the focussing screen would be exposed to the view of the operator. A side arrangement for the admission of the dark slides would also be necessary. Here, then, there is really no practical reason why most of the screwing and unscrewing, and the risk of breakage of lenses, should not be abolished at one fell swoop. How to abolish the trouble and waste of time of fixing the three screws of the legs seems at first sight a greater difficulty, but Mr. W. H. Harrison, who has had considerable experience in tourist's work with preserved plates, long ago published a simple remedy. The top of the stand should be made of a little circle of wood, only three inches in diameter, with three one-inch projections from this circular piece, each projection only one and a-half inch wide. The tops of each of the legs will thus open only one and a-half inch to bite the outside of the projections, where they may be held as usual by three screws. But, as this wooden

Digitized by Google

top is very small, the legs may be carried without inconvenience, without removing the top, when several views in the same neighbourhood have to be taken, so that in fixing the box camera to the stand, it is only necessary to fix *one* screw through the centre of the stand, and everything is ready for use. Of course, when the views are many miles apart, it is best to take the legs asunder, so that they will lie together more in walking-stick fashion. He has tried legs made as here described for many years; they were quickly made by a common carpenter, and have been found more practically useful than those supplied by regular manufacturers. Though the top is small, it is found to give firm and solid support to the camera, even in a rough wind. There is, therefore, no reason, whatever but the want of knowledge of manufacturers of the requirements of practical photographers why the latter should be forced by beautifully made apparatus to waste five or eight minutes over each view, and run the risk of breaking their lenses.

Now for the lenses. Every good landscape photographer knows the value of taking out two or three sets of lenses, because when he has chosen a picturesque point of view to the eye, the lens in camera may exhibit minor objects in the foreground on a large and imposing scale, and dwarf the principal object in the distance to an insignificant little speck. The substitution of a long focus lens, including less angle, is the remedy. But as makers of lenses do not adhere to similar screw threads in the flanges, the unfortunate photographer is usually reduced to the necessity of carrying an extra front to his camera, with other flanges, to fit the second pair of stereo lenses. Should he carry three pairs of lenses, a third front would be necessary. Here, again, if photographic opticians would only agree among themselves to adopt one particular screw thread in flanges for all lenses, from quarter-plate size downwards, it would greatly benefit their patrons. Not only so, but the fact that the purchase of extra lenses involves the carrying of extra wooden fronts to the camera, at present actually causes practical men to buy and use fewer lenses than they otherwise would employ.

Suppose, however, that one screw thread were now in use for all small lenses, the trouble of screwing and unscrewing for each view would not be entirely abolished, so we would recommend, if action be taken to meet these photographic wants, that a standard tube, rather than a standard flange, be chosen. The lenses should be mounted so that they would slide right in and pull out of the standard tube, so that they might be changed in an instant. Thus would a real hindrance to the purchase of lenses be abolished, because buyers would not have the present inconvenience of specially adapting their camera fronts to the change. There is another fault in double combination lenses, as sold by makers of the highest reputation. These lenses are sold with Waterhouse diaphragms for insertion between the glasses, but are not now furnished with front stops, yet with front stops a portrait combination is a more efficient instrument than without them. For instance, front stops will flatten the field of a lens which otherwise would not give sharp definition over a flat surface, so that when flatness of field is required, the photographer has to push pieces of blackened card with a hole in the middle into the hood of a lens, which ought to have been provided with good front stops by the optician.

ELECTRICITY AND TELEGRAPHY.

IT is with great pleasure that we announce that the Queen has been pleased to confer the honour of knighthood upon Charles Wheatstone, Esq., F.R.S.

Our transatlantic friends are certainly well up in telegraph news, informing us of the rapid progress of work doing in England, of which we have not heard the commencement. The immersion of the cable for the Franco-American route, now making in London, is to begin next May, and we are informed that the "Great Eastern" will be employed to lay it. Great endeavours are being made in favour of this scheme, but at present we can safely say that the cable is not yet commenced, although we hope ere long to see some active steps taken in the matter.

Some despatches were spoken of in our papers lately, when Mr. Gladstone spoke in Lancashire, as being the longest messages sent by telegraph in England. They are not behind us in America, where, we are told, that the President's message, consisting of nearly thirteen thousand words, was sent in the space of 7 hours and 40 minutes, without error.

Telegraphy appears to be progressing in Peru. Two companies have lately been established there under very favourable circumstances, with the object of extending the telegraph to some of the principal points in the country. At present, arrangements have been made for extensions from Lima to the port of Callao, Huacho, and Lambayeque, a distance of one hundred and fifty leagues in length; and further extensions from Callao to Pisco and the Chincha Islands (renowned for their guano), about one hundred and ninety miles. The lines, when completed, will be worked by the Morse instrument, on the American system.

A curious experiment has lately been tried by M. Balsamo. Two small magnetized bars of iron, of equal surfaces and weight, were plunged into ozalic acid at the same moment, their opposite poles being inserted—the north of one, and the south of the other. The bar whose north pole was in the acid was found to act as a zinc or a positive element, while the other, whose south pole was dipped in, acted as a copper or negative element, and a current was consequently obtained from the pair.

A new battery was lately presented by M. Balsamo to the French Academy of Sciences. Both elements consisting of iron, the one being immersed in a solution of chloride of calcium, the other in diluted sulphuric acid, the two solutions being separated by a porous cell. The iron in the sulphuric acid acted as the positive element, and the other as negative. The current obtained from this novel arrangement is constant and of considerable intensity.

On the 22nd, the Turkish lines in Asia Minor were temporarily interrupted, and have not yet been announced as being again in order. It fortunately happened that on the same day communication was restored via the Russian route. Since the above date, Indian messages have been forwarded and received over the Prusso-Russian and Persian route to the Indo-European cable, and the lines have been in such thorough good working order that messages from India are now being received in London of the previous day's date.

It is reported that a movement will be made in the Canadian Parliament at Ottawa, in favour of the Government purchasing and working the telegraph lines.

A new thermo-electric pile, the invention of Mr. Farmer, of Boston, U.S., appears to give great results in the deposition of metals, and to give a constant and uniform current; it consists of antimony and copper, the strips or arms of copper protrude outward from the bars of antimony, so as to secure the cooling influence of an air-current, whilst a jet of gas is heating the other extremity. There is some similarity between this and the large pile constructed many years ago by Wheatstone on Marcus' principle, the positive metal of which was an alloy composed of copper 10, zinc 6, and nickel 6 parts, and the negative an alloy composed of antimony 12 parts, zinc 5, and bismuth 1 part. The metals were screwed together, so that their lower junctions could be heated by a jet of gas, and the upper cooled by a current of water.

A novel battery, termed an "electric buoy," is now being experimented upon at Cherbourg. It consists of a zinc plate and a cylinder of carbon attached to a cross piece of wood, having as an exciting liquid the sea water. The inventor, M. Duchemin, claims for it a great variety of applications.

Another variation of a battery has been tried by M. Miergue, of Boufarik, consisting of a cylindrical cell of porous carbon, containing nitric acid, and an exterior cylinder of amalgamated zinc in a cell full of water.

By a telegram from Malta we learn that the Malta and Alexandria Telegraph is interrupted between Tripoli and Benghazi. The repairing steamer "Hawk," left on the first of this month to carry out the necessary repairs.

The Electric and International Telegraph Company have just had their half-yearly meeting, declaring a dividend of 5 per cent. on the half year. We are glad to see that they are about to present a bonus to their staff out of the surplus. The increase in their system during the past year has been 267 miles of line, 2,047 miles of wire, and 754 instruments.

One of the most extraordinary natural phenomena we have ever heard of, is mentioned as having taken place in Rochester, U.S., on the Atlantic and Pacific Telegraph line. One of the wires of this line was down between Rochester and Syracuse; it was discovered that neither section would work. A continuous current of electricity was then observed to be passing over the wire through the several instruments, and this while the batteries were disconnected. The current seemed to be of the volume of a medium sized pipe-stem (sic), and it gave the several colours of the rainbow. With the key open the current flowed in waves or undulations, and from the surcharged wire it would leap over the insulated portion of the key and flow along the wires beyond. The same phenomenon was observed at Buffalo and Cleveland. The gas in the office at Rochester was lighted without difficulty by holding the end of a wire within an inch or two of the burner. The current was intense enough to shock one holding the wires or instruments, and it is stated that one of the employés had his fingers scorched by the current. We should be glad to have some further details of this extraordinary phenomenon.

Some interesting experiments have been performed by M. Poggendorff on the heat developed in the passage of an electric discharge. From these experiments it appears that by the discharge by sparks, or with the addition of conductors, the total heating is less than in the "brush" discharge or without conductors, and from them he concludes that the difference of temperature at the two poles has no relation to the source of the electricity, but only depends upon the manner in which the discharge is made.

The following experiment has been tried by M. Louis d'Henry, as an illustration of the power of magnetism to generate heat, and as one more example of the correlation of physical forces. If a glass flask be placed on a small copper plate, and a magnet with its poles pointed upwards be made to revolve rapidly in a vertical axis below this plate, an increased temperature in the air of the flask will be observed, which may be made sensible by any particular arrangement. It is supposed that by substituting for the plate and flask a copper vessel containing water, sufficient heat may be generated by the rapid action of the magnet to cause the water to boil.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

POROSITY OF CAST IRON—CONVERSION OF METHYLIC INTO ETHYLIC ALCOHOL—THE LIGHT OF THE

Digitized by Google

MAGNETO-ELECTRIC MACHINE—THE MANUFACTURE OF BRONZING POWDERS — GAS FROM WASTE MATERIALS.

THE porosity of cast iron is a well-known fact. Many years ago, Mr. Perkins forced water through thick plates of it: hence it is not astonishing that gases pass with ease. A few years ago, a physician at Chambery was struck with the circumstance that an epidemic of fever occurred in Savoy every winter; and he fancied that he had traced the cause to the use in the cottages of cast-iron stoves, which allowed the gases of combustion to pass into the atmosphere of the rooms. The subject has been investigated by MM. Deville and Troost, and they find, by a very carefully conducted experiment, that hydrogen, carbonic acid, and carbonic oxide do actually pass through the walls of a cast-iron stove, at a dull as well as at a bright red heat. The fact is worth knowing here, for such stoves are often used in this country, and most frequently in ill-ventilated apartments. The amount of gases which pass is certainly not large, but carbonic oxide is an exceedingly poisonous agent, and most of the discomfort experienced in rooms heated by these stoves is no doubt attributable to that gas. The subject deserves the attention of manufacturers, who might possibly devise a tile or clay-lined stove that would diminish the inconvenience we mention, and at the same time economize fuel.

Among the most recent and striking novelties in chemistry we notice the conversion of methylic into ethylic alcohol, which has been observed by Siersch, a chemist at Lemberg. The circumstances under which this change was noticed to take place we shall refer to on another occasion.

In Holmes's magneto-electric machine each revolution developes sixteen currents in opposite directions: hence the light it produces must be discontinuous, being extinguished and relighted sixteen times in the course of each revolution. As the machine makes 500 revolutions in a minute, the interval of time during which the current is cut off is excessively small; nevertheless, M. Jamin thought he could demonstrate the intermittence of the light. He failed to do this, but was able to recognize that the light of the luminous arc was less intense than that given off by the charcoal points, which he attributes to the interruption of the current. Properly speaking, he says we have in this lamp not the discontinuous electric light, but that of the carbon poles heated to intense whiteness, and giving a light nearly uniform. The light of the magneto-electric machine is, therefore, less blue and poorer in chemical rays than that from a lamp excited by a battery, and consequently better adapted for light-houses.

The composition and modes of manufacture of bronze powders are but little known, and some information on the subject may not be without value to many of our readers. Dr. Wagner has made the preparation of these metallic colours a special study, and gives, in Dingler's "Polytechnic Journal," an interesting account of the rise and progress of the industry, and some analyses of recent products. He shows, first, that these colours are really metallic, and are not, as many besides the writer he quotes believe, mixtures coloured with organic pigment, like carmine and indigo. The metals employed are, for the most part, copper and zinc, an alloy of the two being reduced to an impalpable powder by means to be presently described. The proportions of the metals are stated to be as follows:—For a bright yellow shade, 83 parts of copper and 17 of zinc; for an orange shade, from 90 to 94 of copper, and from 6 to 10 of zinc. A red bronze was composed entirely of copper. We append the amount of copper in several specimens, some of them from the French Exhibition.

			per cent.

,,	,,	orange	95·30
,,	,,	deep yellow	81·55

In no instance was tin, silver, or nickel found, but one English specimen contained a little iron. The original mode (and, indeed, that still followed to a great extent) of reducing the alloy to a fine powder is, first to beat it into thin leaves, then to rub the leaves with a scratch brush through a fine iron sieve, and afterwards to grind with oil the powder so produced, the shade of colour required being obtained subsequently by careful heating. Sometimes, however, the alloy is reduced to powder by filing. The particles obtained by filing are necessarily angular and devoid of lustre; they therefore require to be flattened by rolling, after which the powder covers well and reflects light. Rostaing obtains a powder by submitting the melted alloy to the action of a centrifugal machine. Another mode now followed is one we mentioned some time time ago for obtaining metals in powder. An amalgam of the alloy with mercury is made, which latter metal is afterwards driven off by heat. A spongy mass remains behind, which is reduced to a brilliant lamellar powder by rubbing in a mortar. When copper is obtained in powder by a chemical process, such as the reduction of the chloride by heating it with soda and sal-ammoniac, or by precipitating a solution of the acetate of copper with sulphurous acid, or a solution of the sulphate with iron, the powder is always hard and crystalline, and useless for bronzing. Dr. Wagner, however, has produced a very good bronze by the reduction of oxide of copper, as effected in an organic analysis. The special means he employs is passing the vapour of a petroleum oil over the strongly-heated oxide. Taking the composition of a light petroleum oil (known in Germany as Rhigolene) as expressed by the formula $C_{12} H_{14}$, he shows that 16lb. of this oil will reduce 200lb. of oxide of copper. The reduced metal must be allowed to cool in an atmosphere of the petroleum vapour, and the powder is then brought into the scaly lamellar condition necessary for bronze by rubbing it in a mortar. Various and bright shades of colour may be given to this powder by exposing it to zinc or cadmium vapour, and so effecting a sort of cementation of the metals. Lastly, Dr. Wagner states that if an oil containing a small amount of sulphur is used to effect the reduction, a beautiful variegated coloration is produced, which resembles the coloration of peacock copper ore. These last described processes are novel, and may deserve the attention of manufacturers. We need not follow the author into his account of the tungsten, mosaic gold, and chromium bronzes, which offer nothing new.

The experiments now in progress at Woolwich Arsenal on the manufacture of gas from a mixture of Trinidad bitumen and coal remind us of the recent use of various waste materials for the purpose in Germany. Among these are the residues of the manufacture of paraffin, and the refining of petroleum oils. With each of these materials a large quantity of permanent gas of a high illuminating power was procured. Another substance experimented with was the waste grease from the woollen manufacture, which yielded a smaller amount of gas. From a review of all the experiments, however, it is concluded that the use of bituminous oils, in combination with coal or peat for the production of gas, offers no advantages, as regards price, over ordinary coal gas. In small works it may be profitable when manufacturers use up their own waste products.

NOTICES OF BOOKS.

THE student who would read history aright, and who desires to acquire an enlarged and accurate conception of the manners, spirit, circumstances, and condition of our forefathers, and of the influences affecting habits of thought and action in operation in bygone times, which either promoted or retarded national and social, material and mental progress, must extend his reading beyond the historical works which record the rise and fall of dynasties, the contests of political parties, or the "battles, sieges, fortunes," incidental to national and political struggles and revolutions. Some of the bypaths of history offer knowledge as interesting and as practically valuable and important as are presented by what is usually regarded as the main line. In the volume* before us, Mr. Walford invites to an exploration of one of these bypaths, and the book is full of internal evidence that he is completely trustworthy and competent to be a "guide, philosopher, and friend," in the journey. The book is a thoroughly honest piece of hard work well and solidly framed, and perfectly finished. The author's industry and perseverance in fishing in all waters for materials to complete and enrich his work are conspicuous in almost every page, and his industry has only been surpassed by his digestive and manipulative powers, his judgment and skill, as displayed in his embodiment of the ample and fit materials he has collected. In dedicating his work to insurance agents, the author pays a high compliment to their intelligence. To the agent who depends upon mere importunity for obtaining proposals, this book—or any other, indeed—will be of little value, but to an intelligent man representing a sound and prosperous office it will be as a quiver full of arrows which he will not fail to use with a good result. The work is a treasure which agents should highly prize, but it is fitted to prove useful and interesting in a far wider range; the most accomplished actuaries will respect it, we are persuaded, and statesmen need not be ashamed to learn from it. There is probably no single work on the subject treated better arranged and more complete and exhaustive than this, which will enable any man of average intelligence to understand fairly and satisfactorily the principal points in the theory and practice of assurance. It is well fitted to awaken the reader to an appreciation of the duty of assurance, to instigate to the performance of the duty, and to guide him in its discharge in such a way as shall secure most surely the largest possible amount of advantage. The man who masters the contents of this book will feel perfectly competent, acting upon the knowledge it will impart, to select his own office, and will not be a prey to the most importunate of the touting canvassers who may pester him.

The history of life and other assurances is given fully, but far from tediously, in the first division of the work, and is followed by a section containing much curious and interesting matter touching the laws of mortality, population, and longevity. The theory and practice of life assurance are very fully discussed in the last three divisions of the work. It concludes with a quantity of matter specially designed for agents to whom, if it has their attention, it cannot fail to prove of great value. A copious carefully-prepared index adds greatly to the value of the volume. It ought to be stated that Mr. Walford is, to all appearance, a thoroughly independent writer. This book has not been written to order to puff one office or set of offices and to decry another. He so instructs his readers on the cardinal and minor points of the whole subject that he needs not give names of good or of shaky offices; their accounts and balance sheets, if they can be got at, and are honest, will serve the turn, and will either attract or

* "The Insurance Guide and Handbook." By CORNELIUS WALFORD, Barrister. Second edition. London: C. A. E. Layton, Fleet-street.

Digitized by Google

repel the intending assurers who have mastered the handbook and retained the "guide" Mr. Walford has provided for them. The ruck of insurance office advertisements, which one might have expected to see at the end of such a book as this, and which could have been obtained doubtless, are conspicuous by their absence; their absence is creditable to both author and publishers. Mr. Walford's book has much in it that cannot fail to interest the general reader as much as professional men. Unless he has printed very largely indeed, it may be safely predicted that it will not rest at the second edition.

Another work of the same class as the foregoing is the Journal of the Institute of Actuaries.* The current number of this valuable periodical fully sustains its high reputation and that of its eminent contributors. The *piece de resistance* of the number is the first article, by Mr. J. Hill Williams, being on Brigg's method of interpolation, and an admirable translation of the 13th chapter, and part of the 12th, of the preface to the "Arithmetica Logarithmica." Brigg's work is very scarce, and some of the editions published in his lifetime do not contain the matter here translated, which will doubtless prove very acceptable to the readers, or rather students, of the journal. Mr. A. de Morgan furnishes some interesting notes on the valuable statistical works of M. Fourier, the eminent French statist, and gives a specimen table relating to Paris in 1817, which is deeply interesting, as showing the results of the long wars of Napoleon I., and the rapacious conscriptions resorted to for the human *materiel* necessary for their prosecution. The table gives the ages of the males and females by quinquennial steps from 0·5 to 30, and above that by decennial steps to 100 years of age, with the numbers at the several ages, married, single, widowers, and widows. There is painful interest in the remarkable disproportion between the numbers of widows and widowers at the more advanced ages. Between 10 and 15 there were 65 married females but no married males; between 15 and 20, 380 married males and 2,796 married females, 44 widows, and 12 widowers; between 20 and 25, 4,784 married males and 12,099 married females, 362 widows, and 58 widowers. The effects of the conscriptions and of the war, as a producing cause of widowhood, are not fully apparent for several decades. Between the ages of 40 and 50 there were 9,754 widows out of 47,422 women, and 2,180 widowers out of 38,572 men; between 50 and 60 there were 11,476 widows out of 34,578 women—about one woman in every three: the widowers were 3,686 of 34,852 men; between 60 and 70 the widows were 11,446 of 23,087, or about every other woman (!), and the widowers 4,001 of 23,043. There were 45,565 of both sexes of 5 years of age and under, 106,153 from 30 to 40, 2,662 from 80 to 90, and 135 above 90. The numbers of the intermediate ages are in ascending and descending gradations. The Journal contains able papers by Mr. Peter Gray and other writers, including Professor de Morgan, whose "Budget of Paradoxes" is continued.

The subject of the earth's varying presentation towards the sun is both important and interesting, but it is one which nevertheless has hitherto only been illustrated by meagre and incorrect drawings. To supply the place of these is the design of Mr. Proctor's "Sun Views of the Earth,"† which include forty-eight views of the earth, as supposed to be seen from the sun at different hours and seasons. We have also five enlarged sun views of England, and a diagram representing the earth's daily motion in her orbit. The figures are drawn with all the accuracy that could be secured by careful calculation and construction. Sufficient descriptive matter accompanies the drawings, to enable an intelligent use to be made of them by the student. Such a series of views as those before us are of greater value than they appear to be at a first glance. They are not educational only, they are something more. Many important geographical, geological, and meteorological facts are far more aptly illustrated by those views than they could be by any set of ordinary maps. Hence their extensive usefulness and great value, which is enhanced by the clearness with which the whole matter is placed before the reader.

The unfortunate condition of our railway system has led to many suggestions for its improvement. Amongst others, Mr. Samuel Haughton has ventured a pamphlet upon the subject,* in which he summarizes the history of the French railway system, and suggests a thorough railway reform at home. From this pamphlet we gather some very interesting facts connected with French railways. It appears that the first railway constructed in France was in 1823, from St. Etienne to Andrezieux, eleven and a-half miles long, for goods and coals, at a cost of £7,400 per mile of single line; and it was worked by bullocks and horses at a profit of 12 per cent. The first trial of locomotives was by MM. Seguin Frères, on the line from St. Etienne to Lyons. This was a double line, and cost £16,200 per mile. It is curious to note that the first railways were made far from Paris, and by a southern population, whose enterprize is generally considered to be languid. These were followed by lines in the district between Nismes and Montpellier; then from Paris to St. Germain; and in 1837, the two railways to Versailles. In 1838, the Cabinet proposed that the State should construct the great trunk lines, which the Chamber did not approve, but granted several concessions to private companies towards the west, north, and south-west.

In 1841, there were only 323 miles of railway at work in France, which had cost £22,000 per mile, or a total expenditure of £7,016,000 by the companies, and of £130,000 by the State, the net profit being only 3·11 per cent. In 1842 power was given to the State to undertake the main trunk lines, which now connect Paris with the frontiers of France. Notwithstanding monetary crises and other difficulties at the end of 1851, there were 2,213 miles of railway at work in France. Another ten years saw a great increase, which has continued up to the present time, when France counts 9,065 miles of railway at work. This is about one mile for 26 square miles of, country, or for 4,607 inhabitants. This, of course, contrasts very badly with the United Kingdom, where there are 13,289 miles of railway at work, being one mile of railway for nine square miles, or for 2,238 inhabitants. In Ireland we have 1,838 miles open, being at the rate of one mile for 17·1 square miles, or for 3,260 inhabitants. The slow progress in France is variously attributed to want of capital, of enterprise, and of political security, or to greater commercial prudence. In the face of the grumbling and discontent at home, with regard to railway arrangements, it may be consoling to know that our continental neighbours are not much better off than ourselves in this respect. Complaints are constant against high fares, low speeds, delays, charges for luggage, &c., and these emanate chiefly from that important body, commercial men. The remedy recommended by Mr. Haughton for the present unhappy condition of our railway system, is in effect that railways should become public property. The three chief reasons for the public ownership of railways may be shortly stated to be, the more rapid extension of new lines; the reduction of fares and rates; and the almost certainty that lines not earning a profit cannot be maintained in safe working order by private enterprise. The railway public cannot fail to be interested in Mr. Haughton's little book.

Mr. Thomas Gray, who is well known as having taken an active interest in steering and sailing rules recently delivered a lecture on the subject.* The author examines into the probable meaning of the words, "two ships under steam meeting end on, or nearly end on, so as to involve risk of collision," as used in the steering and sailing rules. The author asks whether the quoted words (which are contained in Article 13 of the regulations) mean overtaking ships, or ships at night showing red and green to the stern of another which is ahead. Do they mean two passing ships, or ships showing at night red to red or green to green, &c.? Or do they mean two ships crossing at any angle, or ships at night showing a red light to a green light or a green light to a red light? If not, do the words quoted refer to the only other position, namely, to two ships meeting each other end on, or nearly end on, that is, two ships at night showing each other both the red and the green lights? Mr. Gray observes that if the reader is satisfied that the express direction to port applies to Class 4 only, he has found an answer. Without doubt, the regulations do not expressly direct the use of the port helm unless two ships are meeting end on, or nearly end on; and two ships cannot be approaching each other thus at night without showing to each other both the red and green lights. As the profits of the sale of Mr. Gray's lecture are to be invested in prizes for boys in training ships, who pass good examinations in the rule of the road at sea, we wish the publication every success. Every seaman should read it.

"Aerial Locomotion" (Tinling, Liverpool) forms the subject of a small pamphlet by Mr. George Murray, who describes what he terms a practical method of traversing the atmosphere. Well, it may be practical, but we doubt whether it is practicable We commend Mr. Murray and his pamphlet to the notice of the Aeronautical Society.

The "Management of Health" (Virtue) forms the subject of one of Weale's rudimentary series. It is a manual of home and personal hygiene, and contains some useful practical hints on air, light, and ventilation, exercise, diet, rest, mental discipline, &c. It is by Mr. James Baird, B.A., and interests all who are careful to preserve a sound mind and a healthy body. The author lays down simple rules for the management of health, moderation being inculcated in all things. Those who never lose sight of this golden rule may expect a full measure of that earthly blessing, "mens sana in corpore sano."

"Metals and their Uses" are well discussed by Mr. F. H. Joynson in one of Nimmo's handy books of useful knowledge (Nimmo, Edinburgh). The information is brought down to the latest time, and special prominence is given to iron, steel, and Bessemer steel, &c. Although written somewhat in the popular style, this little book will be found to contain some useful hints to workers in metals. Another of Nimmo's handy books treats of "Free-hand Drawing." It is by an art student, and will be found a very useful guide to those who wish to learn the art of ornamental, figure, and landscape drawing. The book, which is profusely illustrated, commences with the first principles of drawing, and gradually leads the student on to the highly finished works of the pencil.

"Hardwicke's Science Gossip" (Hardwicke), appears very regularly every month, and is always full of interest to the student or amateur in science. The last number contains an interesting article, by Mr. M. C. Cooke, on the hair of Indian bats microscopically considered In the same number, and in the previous one, also, are articles on that domestic nuisance the bug, which are highly amusing and instructive. An article on the highest mountains, too, may be perused by all with benefit. The signification of the names by which they are known is worthy of attention, as they are singularly well chosen for mountains of such exceptional height as those under notice.

THE INDUSTRIAL ENTERPRISE OF HUNGARY.

IT was expected that the reorganization of Hungary would have driven all energies in a political direction, and that attention would have been turned to anything rather than the development of the material interests of the country. Such, however, has not been the case, but, on the contrary, confidence has everywhere prevailed, and an activity which no one ever anticipated has been produced in every direction. A plentiful harvest, after several years of failure, has led to an unparalelled export trade, and the money thus realized has stimulated industrial and commercial enterprise. The result is that new enterprises are everywhere springing up. New branches of industry are being opened out, and old ones greatly enlarged. The Hungarian Minister for Agriculture and Commerce is therefore able to report favourably of the progress made in Hungary during the past year. The report first enters upon the details of the post-office and telegraphs. Notwithstanding the difficulties which beset the working of the departmental system in Hungary, the post-office produced 5 per cent. more than the anticipated revenue. The

Digitized by Google

number of post-offices in Hungary and Transylvania, which had been 938, has been increased within the last eight months by 136 new offices, while more rapid intercourse between the different offices has been provided for. The telegraphs yielded 45 per cent. more than in the corresponding period of the year 1866. Whereas formerly there were 136 telegraph stations, there are now 152; the length of lines was 814 German miles (4½ to the English mile), now it is 895 miles. 158 new post-offices and 186 more miles of telegraph lines, with 57 stations, have been opened. In order to form telegraph officials, a course of instruction has been established in Pesth, which has already given 69 competent persons. Commercial progress is not very clearly defined by figures, for certain local reasons. An approximate statement, however, of the chief exports is given, and from this we learn that 16,500,000cwt. of grain have been exported, 1,890,000cwt. of flour, 600,000cwt. of rape seed, 331,000cwt. of tobacco, 304,000cwt. of wool, 638,000 of wine, and 1,423,000 of cattle, sheep, horses, and pigs.

With regard to the industrial enterprises, we find the report gives the first place to steam flour mills, two of which with large capital are at work, whilst ten more are in progress. These mills have become the chief industry of Hungary, the tendency to export flour instead of grain being greatly on the increase. The other manufactures are represented by a mechanical engineering establishment, a chemical factory, a flax-spinning mill, several spirit refineries, a factory for railway waggons and agricultural machinery, a brewery company, a leatherware factory, and a woollen manufactory. There are also steam navigation and steam tug companies in a flourishing condition. According to the report, the iron industry has likewise taken a new start after the long depression, so that a yield of 600,000 tons of raw iron is anticipated for the present year. The Minister mentions the Exposition of last year as having contributed to stimulate energy. Of 300 exhibitors, 161 received distinctions; among them 17 gold medals and 42 silver ones. If we look at agricultural machinery we still find cause for congratulation, for had it not been for the general introduction of steam thrashing machines, the grain could never have been exported in time. Altogether, the energy displayed and the progress made in a comparatively short time augur well for the future of Hungary. Although she may not at present be able to compete with more advanced countries, she is going the right way to overtake some of us. In fact, she has already done so to some extent, inasmuch as in the Universal Exhibition of 1867 Hungarian flour beat all competitors.

TRIAL OF A TEN-INCH ARMOUR PLATE

IN these days, when it must be evident to all that it is time we stirred ourselves in the matter of iron ships and defences, if we mean to retain anything like our old position afloat and ashore, it is gratifying to find that the great iron armour-plate makers are equal to the emergency. It has been a question whether armour-plates could be made as thick as 10in., and at the same time of similar quality for resistance to thinner plates. This question has now been decided by the results of some experiments which were made last week on board the "Thunderer" target ship. A plate from the rolling mills of Messrs. John Brown and Company Atlas Steel Works, Sheffield; 10in. in thickness, by 15ft. in length, and 3ft. 9in. in broadth, was fairly tested before artillery. It was selected as a "test" plate from a score of plates manufactured by Messrs. Brown for the central broadside armour of the "Monarch." The plate was bolted on to a wooden backing of upwards of 4ft. in thickness, supported by iron and oaken beam struts of immense strength. The gun was the ordinary test gun—95 cwt. 68 smooth-bore, but on this occasion fired with 16lb. in lieu of the ordinary 13lb. of powder. The distance between the muzzle of the gun and the face of the armour-plate was 25ft. Nine shots were fired, and all struck the plate within a square space of 34in. The greatest indentation made was only 1·7in., and the least 1·5in.; no cracks, surface or otherwise. The trial, indeed, gave the plate an extraordinary degree of credit. It was the first 10-inch plate tried on board the "Thunderer"; but, in comparison with a series of 8-inch and 9-inch plates previously tested on board, its resisting powers to the impact of shot was very much in excess of what was simply due to its exceptional thickness. The plate will be sent to Shoeburyness, where it will be further experimentally tested with the 10-inch rifled gun and maximum charges of powder. This plate has thoroughly settled the question above referred to, and has shown that thick plates can be had of the same quality for resistance as thinner ones. This is proved by the circumstance that on the plate being taken from the backing after the severe test it had undergone, it was found to be very little bulged, and to have only two small cracks on it, and no separation of the lamina could be detected in the bolt holes. There is no doubt that thick plates of this kind are what are required for fortifications; and, as they can be made at a moderate cost, as wide as 5ft. or 6ft, and 20ft. long, we cannot see why they should not be at once adopted in our defences.

INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of the Institution of Civil Engineers, held January 28th, Charles Hutton Gregory, Esq., president, in the chair, the paper read was on the relation of the fresh-water floods of rivers and streams to the areas and physical features of their basins; and on a method of classifying rivers and streams, with reference to the magnitude of their floods—proposed as a means of facilitating the investigation of the laws of drainage, by Lieut.-Col. P. P. L. O'Connell, R.E., Assoc. Inst. C.E.

After referring to what might be termed the first stage of natural surface drainage, subsequently carried on and completed by rills, streams and rivers, the author observed that streams draining large areas were not subject to sudden floods caused by short smart showers, and that a lake, like the extension of the area of a drainage basin, was a moderator of the flood discharge, resulting from a given rate of rainfall. There were other natural moderators which were more or less effective, as, for instance, a porous, absorbent soil, and the foliage of dense forests, but the latter had apparently the property, in some situations, of increasing the actual amount of rainfall, which counterbalanced its effect as a moderator of river floods. Snow might, according as it thawed slowly or rapidly, be a moderator or the reverse. Again, when a tributary in flood flowed into a large main river, the channel of the latter also acted as a moderator. If a series of natural basins could be found, increasing regularly in area, having physical features as to slope, soil, &c., all tending in the same degree to discharge the rain falling on them, and if the distribution of the rain were the same in all these basins, then, doubtless, the rate of discharge in floods might be described graphically by some regular curve, the abscissæ of which would denote the area drained, and the ordinates the flood discharge per second. This curve would be concave to its base, and the tangent at its origin would have a value representing exactly the maximum rate of rainfall. Such, however, were the diversities of physical features in river basins, and in the distribution of rainfall in the world, that the search after the desired series of natural basins possessing exactly similar characteristics would probably be a vain one. This was to be regretted, for rivers small and great might alike be referred to some such curve, and classified as flood dischargers, according as they took up positions near to or distant from the curve.

To supply the place, as a classifier, of this unknown curve, the author suggested the use of the common parabola, as follows:—Let x, the abscissa of a point in the curve, represent the area in square miles drained by a river, and y the ordinate of the same point, represent the number of cubic yards discharged per second by that river. Then, in the common parabola, $y = M. \sqrt{x}$, where M might be termed the modulus of the river, or of its drainage basin, as a flood producer. When M was large, it would indicate that the physical features were such as to slope, soil, total amount and distribution of rainfall, as to give the river and its drainage basin a high place in the classification. When M was small, it would, on the contrary, show either that but little rain fell on the basin, or that it possessed some of those physical features which tended to moderate floods. With the view of illustrating how far this method of classifying rivers as flood producers was likely to prove useful, reference was made to some facts respecting the Mississippi and its tributaries, as recorded in the report on that river, by Captain Humphreys and Lieutenant Abbot, which tended to show, in the author's opinion, that the method might be usefully, if cautiously, applied.

Certain exceptional cases of river floods were next alluded to, and regret was expressed that data sufficiently extensive and accurate for the purpose of testing very rigidly any method of classification had not yet been collected. The author had, however, prepared a table, exhibiting a few of the physical features of some of the principal rivers of North America, Europe, and India. This table gave the area of the drainage basin of each river in English square miles, the flood discharge of the river in cubic yards per second, with the name of the authority for this statement, the flood discharge of the river in cubic yards per second per square mile drained, and the values of M in each case. The facts so collected were also exhibited in diagrams. After commenting upon the range in the values of M thus recorded, it was observed, that whereas, in the case of large rivers, the parabola expressive of the relation between the area drained and the discharge per second might, without sensible error, be supposed to have its apex situated at the origin of the co-ordinates, in the case of small districts this supposition would lead to error. In the latter instance it became necessary to ascertain, at least approximately, what was the maximum rate at which rain fell in the district, and to place the origin of the co-ordinates at a point in the curve where the inclination of the tangent to the axis of x should correctly represent that maximum rate.

For the sake of illustration, it was assumed, that a district existed in which the maximum rate of rainfall was five inches an hour, and the maximum value of the modulus M was 20. This required that the origin of the co-ordinates should be situated at a point in the parabola where its geometrical tangent was inclined to the axis of x, at an angle whose trigonometrical tangent was 120. If x^1 and y^1 were the rectangular co-ordinates of the curve, measured from this point, its equation was—

$$y^1 = 20 \sqrt{x^1} - \frac{y^1}{120},$$

the areas being measured in square miles, and the discharges in cubic yards per second. But as, for small districts, it would be more convenient to measure the areas in acres, and the discharge in cubic feet per second, the formula became, when adapted to these new measurements—

$$21.4 \sqrt{x^1} - \frac{y^1}{5}$$

very nearly, or after the solution of this quadratic equation,

$$y^1 = -45.796 + \sqrt{2097.28 + 457.96\, x^1}.$$

A table, computed by this formula, was then given, showing the discharge in cubic feet per second from districts increasing in size from ten acres to five square miles; and it was stated, while the discharge from an area of ten acres represented a rainfall of 3·56 inches an hour, that from a district having an area of five square miles represented a rainfall of only ·36 of an inch. It was stated, that in rivers whose basins were by no means small, very extraordinary floods might occur in years not remarkable for large totals of rainfall; and in conclusion a few statements and quotations were given, as affording examples of flood moderators.

AERONAUTICAL SOCIETY OF GREAT BRITAIN.

THE council of the Aeronautical Society have decided upon holding an exhibition in London of objects connected with aeronautical science in the month of June. Arrangements have been made for the exhibition to be held at the Crystal Palace, where ample opportunity will be afforded for experiments. The importance and interest of some of these experiments are indicated by the fact that the Shipwrecked Mariners' Society have allotted £50 as a prize in connexion with one of the objects of exhibition—viz., "the best form of kite, or other aerial arrangement or modification thereof, for establishing a communication from a wreck on shore or between two vessels at sea." The late very successful experiments in Paris, conducted by M. Giffard with a captive balloon, have suggested their repetition upon the forthcoming occasion, when Mr. Glaisher will probably prosecute further experiments, and an opportunity will be afforded to inventors to propose means for controlling ascent and descent without loss of gas or ballast. The objects for exhibition, and for which prizes will be offered out of the funds now raising, are light engines and machinery, complete working aerial apparatus, models (working and stationary), plans and drawings, articles of interest commemorating previous experiments, kites or other similar apparatus proposed to be used in cases of shipwreck, traction, or in the attainment of other useful ends; paintings of landscape and cloud scenery as observed from a balloon. A number of

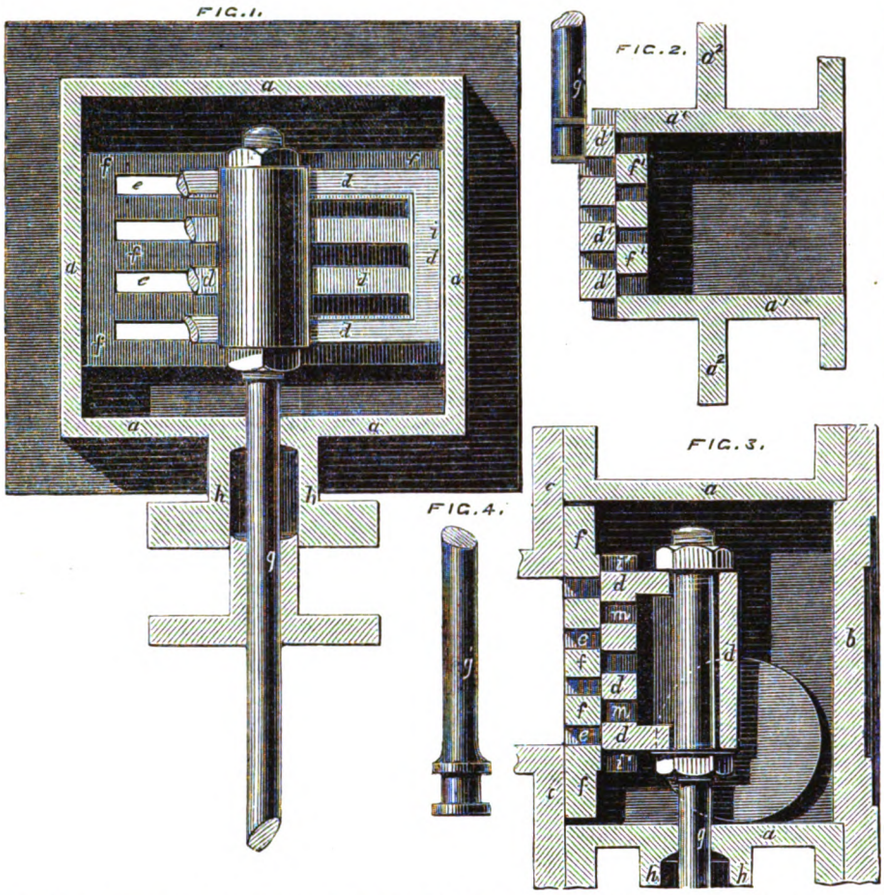
IMPROVED GRIDIRON VALVE.

BY MR. E. BLAND.



scientific gentlemen in America have associated themselves, and have appointed a secretary to correspond with the Aeronautical Society and to aid in this exhibition. The interest excited among inventors in this and other countries has been manifested so strongly that, although the idea has only been made known through the members of the society, already many new inventions have been promised for exhibition. The display of light engines particularly is likely to be large, and further applications for space are being made to Mr. F. W. Brearey, the honorary secretary, at the Crystal Palace.

IMPROVED GRIDIRON VALVE.

MR. EDWARD BLAND, of Bury, Lancaster, has patented some improvements in the use and application of the common gridiron valve. In his arrangement the steam and exhaust valves are placed in separate compartments, and as near to the inner side of the cylinder as the thickness of metal of the cylinder side will allow. The admission valves are placed near the ends of the cylinder, and at any convenient part of the cylinder's circumference, and the exhaust valves are also similarly placed on any other part of the cylinder's circumference not occupied by the inlet valves. The object of using these valves and placing them in the positions mentioned is to prevent undue waste of steam by having as little space as possible between the valves and the interior of the cylinder.

Figs. 1 and 3 of the accompanying engraving show the compartment and its valve for the admission of steam, *a* being the outer part of the compartment or chest; *b* the cover, *c* the cylinder flange, or that part of the cylinder to which the compartment or chest *a* is fixed. The parts marked *d* show the gridiron valve, and in fig. 1 a portion of the valve is broken off to show the openings *e* passing to the cylinder. The seating on which the valve *d* works, and through which the openings *e* pass, is marked by the letter *f*, and the rod for moving the valve is shown at *g* passing through the stuffing box *h*, and guides to keep the valve in its place are shown at *i i*. Fig. 3 is a section through the middle of fig. 1, the valve being shown closed or covering the openings *e*, and when the valve is wide open the openings *m* in the valve correspond with the openings *e* in the seating, and the steam passes through the openings *m* and *e* at one and the same time.

Fig. 2 shows the way in which each exhaust valve is placed near the interior of the cylinder. The valve is shown at d^1, and the seating at f^1; the compartment carrying the seating is marked a^1, and the flange a^2 is used to secure the said compartments a^1 and the valve seating f^1 to the cylinder. The rod g^1 for working the valve passes through a stuffing box placed near the cylinder end so as to allow the valve d^1 to work as near the cylinder's circumference as may be convenient.

Fig. 4 shows another view of a portion of the rod g^1 attached to the valve d^1. These valves are placed in any convenient way so that their reciprocating motion is in a direction parallel to the axis of the cylinder of the engine, or at any angle to the axis. Motion is given to the valves by tappets, cams or eccentrics. The openings in the valves and seatings are shown of a rectangular form, there being three such openings *m* in the valve and four in the seating *e*. The number of these openings may be varied according to the traverse wished to be given to the valve. Four valves and seatings are used to each cylinder, two for the admission of steam and two for the exhaust, one for admission and one for exhaust being attached to each end of the cylinder.

INSTITUTION OF MECHANICAL ENGINEERS.

THE twenty-first anniversary meeting of the members of this Institution was held on Thursday, January 30, in the Lecture Theatre of the Midland Institute, Birmingham, Sampson Lloyd, Esq., Vice-president, in the chair.

The Secretary (Mr. W. P. Marshall) having read the minutes of the previous meeting, the annual report of the council was then presented, which showed the very satisfactory progress of the Institution during the past year, and its highly prosperous condition, with a large increase in the number of members; and reference was made to the large and important meeting of the Institution held in Paris last summer, during the period of the International Exhibition. The annual election of officers then took place, John Penn, Esq., being elected President of the Institution for the ensuing year. Several new members were also elected.

The first paper read was "On the Transmission of Power by Water Pressure, with the Application to Railway Goods Stations, Forge and Foundry Cranes, and Blast-furnace Hoists," by Sir William G. Armstrong. In the employment of water pressure for the transmission of power, the high pressure required is obtained by means of the "accumulator," consisting of a large vertical cylinder, fitted with a plunger, from which is suspended a loaded weight-case, to give pressure to the water pumped in by the engine. The accumulator is thus a reservoir giving pressure by load instead of by elevation, the load generally used upon the plunger being such as to produce a pressure of 700lb. per square inch; and from the cylinder of the accumulator the water is conveyed by a pipe to the various places where motive power is required. The water therefore acts as a carrier of power, taking the place of shafting; and it possesses a great superiority to shafting in the cases of working machines which are scattered over a wide area and intermittent in their action, and also where the quantity of power to be transmitted is subject to great and abrupt variations. Water pressure also possesses the advantage of communicating to machinery a much more controllable and adjustable motion than shafting, while the absence of elasticity in water gives great steadiness and precision to the movements of machines actuated by water pressure; but, on the other hand, expansion being impracticable, the quantity of water expended is not proportionate to the load, but remains the same, whatever may be the resistance overcome. To obviate shocks in machinery worked by water pressure, owing to the non-elastic character of water, the machines generally require the introduction of "relief valves," consisting of small clacks, opening against the pressure in the supply pipes, and yielding to any back pressure on the pistons that exceeds the accumulator pressure. The widest application of water pressure, as a means of transmitting power, is in docks, where the water-pressure machinery is now most extensively used for the purpose of opening and closing the gates, swing bridges, and sluices, and also for hauling ships through the locks, and discharging and warehousing cargoes. One application, presenting very novel features, is for the purpose of shipping coals at Goole Docks, on the River Humber, where the coal barges are floated into a cradle, and then lifted bodily to a considerable height, and turned over into a shoot, which delivers the coal into a ship alongside. At the goods station of the Paris and Lyons Railway in Paris, a number of water-pressure cranes are now in operation, for the purpose of loading and unloading the waggons; and also two hydraulic engines driving capstan heads for hauling the waggons in the station yard. The cranes are adapted to turn as well as to lift and lower by the water pressure, the jib being a fixture to the crane pillar, which is made to revolve by means of a chain passing round a wheel at the base of the pillar, and worked by a pair of hydraulic presses placed horizontally. The lifting press is also placed at the base of the crane pillar, the lifting chain being conveyed upwards through the centre of the pillar, and thence over the end of the jib. The valves for lifting and lowering and for turning are slide valves, worked by hand; and the cranes are either of single power, having a simple ram alone, as in an ordinary hydraulic press; or of double power, having a bored cylinder with combined piston and ram. In the latter case, the lower power is obtained by admitting the water pressure upon both sides of the piston, giving an effective pressure proportionate to the area of the ram only; while for the higher power the upper side of the piston is opened to the exhaust, leaving the pressure to act upon the lower side only, when the effect is proportionate to the area of the piston. A new arrangement of hydraulic crane has also been introduced subsequently, having the lifting cylinder placed vertically, so as to form the crane pillar; and in some cases the crane has been constructed for lifting only, without any turning power, which is the simplest and cheapest form of hydraulic crane that is made. Water-pressure is also employed at the writer's works at Elswick for working the cranes in the foundry and forge, the lifting press and the pair of turning presses for each crane being situated horizontally below the floor; and the lifting chain passes over pulleys on a traversing carriage, which runs upon the top of the horizontal crane-jib, and is hauled inwards or outwards by a pair of hauling presses fixed upon the crane pillar. By means of these hydraulic cranes very heavy forgings are manipulated under the hammer with complete precision and great saving of time and labour. Another application of water pressure has been made to the working of hoists for blast furnaces, for raising the materials for charging the furnace; the two cages being connected by a rope, so as to counterbalance each other, a pair of lifting

Digitized by Google

presses, one to each cage, are fixed vertically at the sides of the framework of the hoist, the two being worked in conjunction by a single valve, so that while the pressure is admitted to one press the water is allowed to escape from the other. This apparatus affords a convenient means of obtaining the increased velocity of working required for raising the increased quantity of materials consumed in the present larger and higher blast furnaces.

The next paper was "On the Allen Engine and Governor," by Mr. Charles T. Porter, of Manchester. In the construction of this engine the object aimed at has been to attain the greatest economy in expansive working, by having the full boiler pressure in the cylinder at the commencement of the stroke, with a sharp cut-off, avoiding reduction of the steam pressure by wire-drawing; although the slide-valve is worked with a direct continuous motion, instead of employing a liberating or disconnecting valve-gear. An invariable exhaust is also obtained, allowing the free discharge of the steam with all degrees of expansion. The engine admits of being worked regularly at the unusually high speed of 600ft. to 800ft. per minute speed of piston, and maintains complete steadiness of motion at this high speed; it also gives great uniformity in the driving power throughout the revolution, in consequence of the reciprocating parts being made to move at so high a speed, that their inertia compensates for the high pressure at which the steam is admitted at the beginning of the stroke; while in the latter part of the stroke, when the steam pressure is diminished by expansion, the power previously imparted is given out again in bringing the reciprocating parts to rest. The engine has a single horizontal steam cylinder, and works an air-pump direct from the piston-rod prolonged through the outer end of the cylinder. The steam valves are two separate slide-valves, one for each port, and both in equilibrium, worked with independent motions so as to effect a sharp cut-off in each case, the motion of one valve being rapidly accelerated at the same time that the other is greatly retarded. There are also two separate slide valves for the exhaust, one for each port; but these move together, and are driven by the same valve rod. All four valves are worked from a single eccentric upon the crank shaft of the engine, and the eccentric strap is made with a curved slot on the inner side, corresponding to the ordinary expansion link; the two steam valves are worked from the sliding block in the slot, through the intervention of two bell-crank levers upon an intermediate rocking shaft; while the exhaust valves are worked direct from a fixed point at the outer end of the slot, and have thus an invariable travel, affording a uniform freedom of exhaust, whatever degree of expansion is given by the link motion. The eccentric being set to correspond in position with the crank, without any lead, a correct valve motion is obtained, giving the same cut-off for each end of the cylinder. The position of the sliding block in the link-slot is adjusted by a lever from the governor, which thus controls the engine according to the work by regulating the grade of expansion, instead of by the ordinary means of a throttle valve in the steam pipe. The air pump consists of a cubical box filled with water, in the lower part of which works a plunger attached to the piston rod of the steam cylinder; the inlet and outlet valves are all placed in the top cover of the box, and the plunger thus works always in solid water, as the air entering through the inlet valves from the condenser passes at once direct to the outlet valves, without becoming mixed with the water in which the plunger is working. The valves are india-rubber discs, guided upon centre spindles; and a light spiral spring is added on the back of each valve, to give the required promptness in closing, as the valves have to close 200 times per minute at the high speed at which the engine is worked. The governor has been designed by the writer as a modification of the ordinary Watt's centrifugal governor, for the purpose of increasing its sensitiveness and quickness of action. The balls are made very much lighter, so as to correspond with the much higher speed of revolution; and the connection of the radius rods to the centre spindle of the governor is made with forked ends, having considerable width of fork, and fitting upon a pin which passes through the axis of rotation, whereby the friction at the joints that opposes the rise and fall of the balls is reduced. The balls in rising pull up a heavy weight sliding on the centre spindle. In consequence of the increased sensitiveness obtained with this construction of governor, it is found to regulate the speed of the engine within a range of only two per cent. variation of speed under the extreme variations of load; and a variation of five per cent. in the speed would carry the governor through its entire range of action, and cut off the steam entirely from the cylinder. In practice the steam stop-valve is always set wide open, and the engine runs under all circumstances with complete steadiness and uniformity of motion, without requiring any attention. One of these engines was worked at the recent Paris Exhibition at the speed of 200 revolutions per minute, or 800ft. per minute speed of piston; and other engines have also been running for some time at different works in Manchester, one at the above speed, and the others at 600ft. per minute.

It was announced that the annual meeting of the Institution for the present year would be held at Leeds, in the course of the summer, during the time of the Art Exhibition at Leeds.

The meeting then terminated. In the evening a number of the members and their friends dined together, in celebration of the twenty-first anniversary of the Institution.

THE GIBRALTAR SHIELD AND THE TEN-INCH GUN.

WE reproduce the following critical article upon the above important subject from the "Standard" of Saturday last:—It has lately been our duty, more than once, to call seriously in question statements made respecting certain departmental trials, and we very much regret that we are bound, in the interest of truth and fair play, to question the account given during the present week by a contemporary of the single shot fired from the 10-inch rifled gun against the Gibraltar shield. The particular sources from which that contemporary draws its inspiration is very well known; and, with the most serious interests of the State involved as they are in the present discussion upon the proper nature of iron land defences, it cannot be permitted that misstatements should be allowed to circulate without public contradiction.

The "Pall Mall Gazette" says:—"The Gibraltar shield was again fired at on Wednesday (22nd instant)" by the 10-inch muzzle-loading rifled gun. So far true. Wednesday was a miserably wet, uncomfortable day, and by the ordinary train there arrived at Southend, Colonel Inglis, R.E., the reputed designer of the shield, and his assistant, Lieutenant English, R.E., who proceeded straightway to the shooting ground at Shoebury. The trial was not made before the Ordnance Select Committee, nor the Iron Shield Committee. Only one round was fired—"a Palliser shell of 896lb. weight; the range was 70 yards, but the charge was reduced (to 54lb.) so as to represent a full charge at 400 yards." Not another soul was present but these two engineers, saving Captain Noble, R.A., who took the velocity of the shot on impact. No intimation was given to the press, no one on the part of the public saw what was done, and there was no reporter present to record the proceedings. If the trial had been a recognized official one, we should have published the details, as we regularly do; but it is obvious that a considerable amount of inconvenience might be incurred if all the trials and experiments made in all the Government departments were to become items for newspaper comment. Departmental trials we have been always ready to consider as equivalent with manufacturers' trials in their own factories, and we have not attempted to discuss all the experiments made for the progress of works on account of the inextricable confusion of ideas that might be thus expected to prevail. Of course, under present circumstances, we have no alternative about accepting the figures and details given, although some doubt naturally arises as to a velocity of "1,210ft. per second," being sufficient for "54lb. of powder."

The shell struck the target on "a slight inclination, perhaps as much as 8 deg."—perhaps a little more, as the shield itself has been knocked, by the battering it has had, very much askew, at least 10 deg., and no one but those concerned can now tell where the 10-inch gun was placed, as it has since being removed to the sea-wall battery. "It struck," we are told, "in the centre of the place below the port;" and, we will add, knocked out a notch in the lower part of the 5¼-inch front plate, the piece broken out measuring some 16in. along the base, and not less along its sides. "It—the shell—did not penetrate," we are told—an assertion which undoubtedly leads to a disquisition on the actual meaning of a very common English word. What is penetration? The 10-inch shell pierced the front plate, cracking it into all but four pieces; it pierced the second or inner 5-inch plate, cracking it right asunder up to the port sill, and the protruding nose of the shell, driving up and cracking (with a gaping four-rayed fissure many inches in length) a huge mound in the 1½-inch skin plate, 8in. from the back surface of the 5-inch plate to the centre of its dome. All the four deep longitudinal girders which were riveted on, and bolted up to the rear of the target to strengthen it, were cleared clean away, only stumps of some two or three feet in length remaining attached to the shield at one side, the *debris*—we counted seven pieces, each over 3ft. long—lying strewed on the ground. In short, the shell struck lower down than the centre of the space below the port, and came against that part of the shield which derived support, not only from the girders, but from the flooring and propping of iron 5-inch bars and plates which had been put against it behind to secure it in position. Whether this is or is not penetration we leave the public in their judgment or knowledge of that mother tongue we all desire to speak correctly to decide. The shield is professedly and actually 12in. thick, and the hole made by the shell is certainly not less than 16in. in depth from the surface of the shield to the farthest point of the impression of the head of the shell at the back of the hole. The axis of the shot hole appears to be something like 20 deg. to the face of the plate, showing the high inclination of the line of fire, which practically increased considerably the amount of iron plate to be penetrated beyond the reputed twelve inches. Notwithstanding this, however, but for the girders and props the shell would have gone clean through to the rear, and then there could have been no argument about "penetration."

We will briefly complete the description of the effects of the 10-inch shell. The indent of the front plate is not less at the shot hole than three inches, the buckling extending to the extreme edges of the shield on both sides. The shot hole itself is more than a foot across, a great fissure 1½in. wide running upwards from it through a former shot punched completely to the top edge of the plate. Downwards another great crack runs through the Rodman indent to a bolt hole, and thence completely through to the bottom of the plate. The above on the proper left. On the proper right a third crack goes in a zig-zag direction through a bolt hole towards the bottom of the shield. Below the shot hole a fourth crack extends to a bolt hole within 8in. of the bottom of the plate. The vertical split of the inner plate extends with a gape of 1¾in. from the base of the plate to the port sill, where the plate is seen separated, one half projecting 2in. in front of the other. The back skin also shows a fissure half through on the plane of the port sill. At the rear 14 bolts are broken off round the hummock raised by the point of the shell in the skin plate.

As to the main bolts, we cannot say what was the damage, nor whether they were screwed up tight or not. One, at least, is admitted to have been "probably" broken, and, certainly, another is 8in. from the straight; the rest stick out in disastrous-looking condition, surrounded by their broken wood tubes, with the dilapidated cork and iron washers pendant from their extremities. The wreck is terrific; and if another shot were fired above the port hole, where the girders are still good, the chances are that the entire shield would be rent in twain, and would fall asunder. The whole fault of the Gibraltar shield lies in the design and in the construction. There is no reason for finding any fault with Messrs. Cammel for their iron or their workmanship. The wonder is, not that the shield is so much damaged—we should like it placed in Palace-yard, that all the world might see and judge for themselves—but that the fibre of the iron has so clung to its terrible duty, and been so staunch and true to those who forged it. "It is, indeed, only fair to the designers of the Gibralta shield that they should have the benefit of the publication of this result"—but in which we assuredly do not concur in is, that it "exhibits the shield in a more favourable light than any of the former experiments have done." On the contrary, the effects of the 10-inch shell, and the publication of the truth of those effects must prove—if anything can possibly so prove—disastrous to those who designed the £35,000 worth of shields of this class, the erection of which we hear with sorrow is still going on at Gibraltar, Malta, and Bermuda.

Neither can we admit, after this exposure, that this departmental trial "effectually disposes of the 'laminated' (sum of the squares of the thickness) argument," against which our contemporary and the Royal Engineer's Department have protested. "This argument," our contemporary thinks, "was disposed of by the considerations it lately urged." Those considerations were based upon another departmental trial of no more value than the one we have just described.

That trial referred to in a previous article in the "Pall-Mall Gazette" took place on 29th July. The facts are these. The 7-inch solid plate held the shot in its substance when fired at by a 15lb. charge. The two 3½-inch plates were fired at with charges of 14lb., 13lb., 12lb., 11lb.—the first going clean through altogether; the 13lb. and 12lb. charges went through the front plate, bending out the broken ends of the back plate nearly at the angle of 45deg.; the 11lb. charge nearly pierced the front plate, driving up a great hummock in the rear one. Eleven pounds and a-half charge should, therefore, be much nearer the penetrative power than the 14lb. given in the "Pall-Mall." Against the other target made up of three 2½-inch plates three rounds with charges of 13lb., 12lb., 11lb. were fired, the two first going clean through, and the 11lb. charge piercing both front and back plates, and being a truer equivalent than the 13lb. charge put down by our contemporary. It

AIR COMPRESSING ENGINE.

BY MR. J. G. LLOYD, OF BLAINA.

FIG. 1.

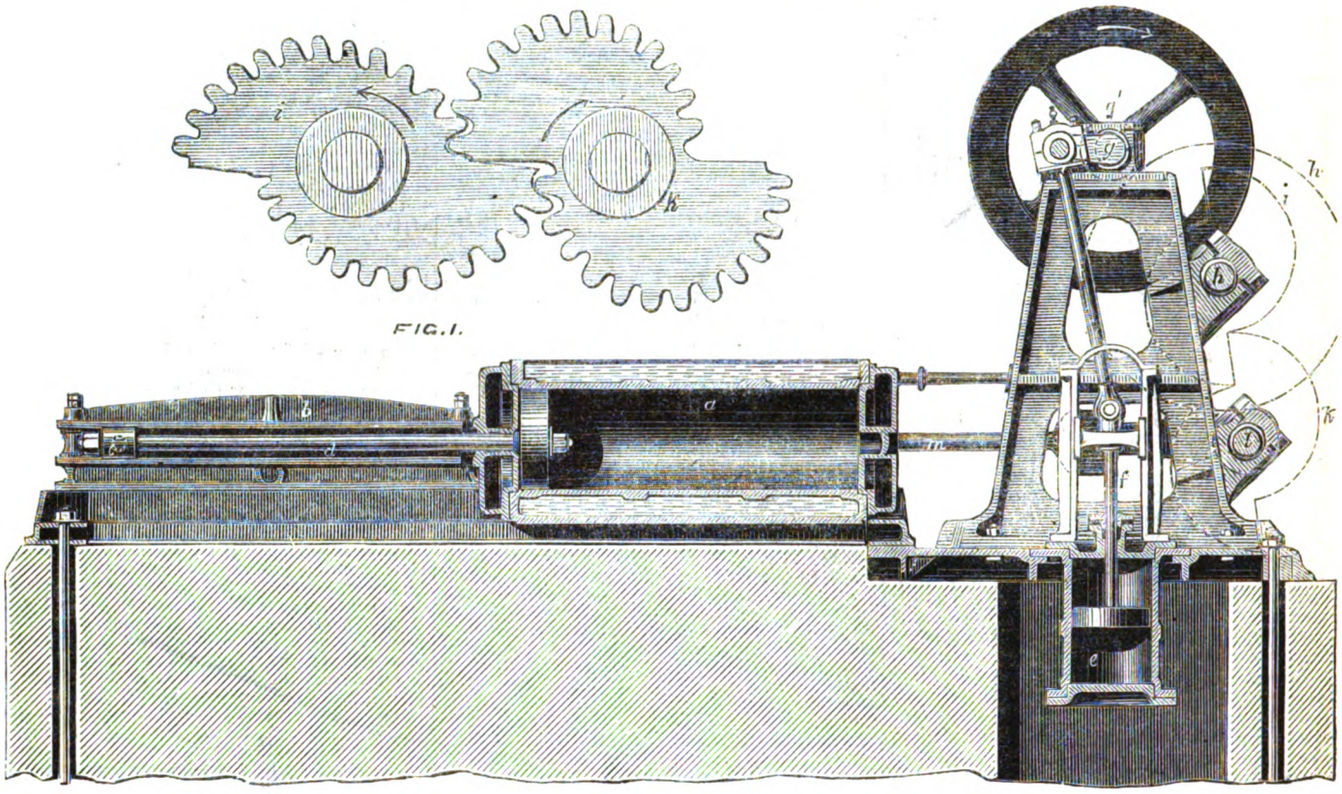

FIG. 2.

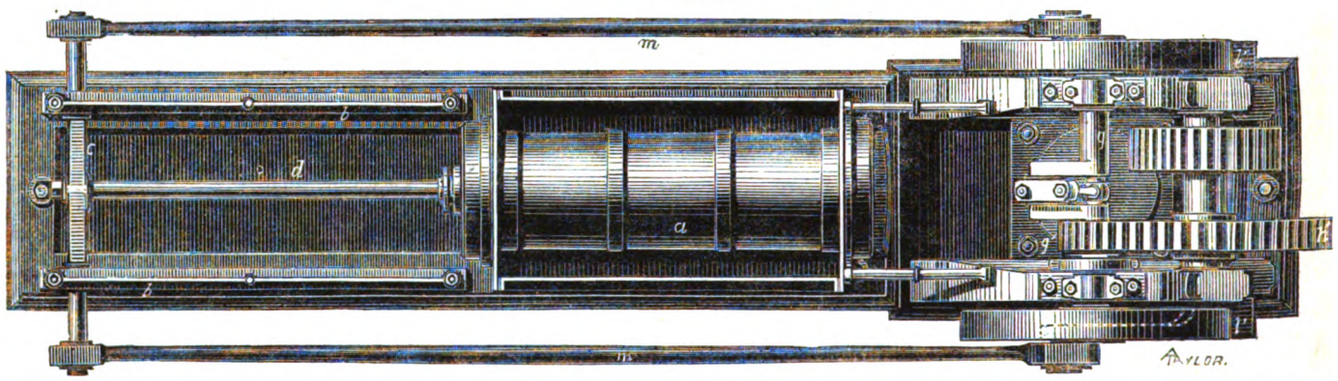

would have been well, therefore, if more attention to being "scientifically correct" and "dispassionately just" had been considered before this erroneous statement had been made.

There is something, too, very mythical about the "wobble" of the shot, which, according to the "Pall-Mall" makes bigger holes at 70 yards, and yet does less work than at 200 yards. For ourselves we abide by the rule laid down by the Ordnance Select Committee, and shall continue to do so until that committee proves the error of the rule by their own experiments, or we are ourselves convinced of its fallacy on reasonable grounds. Certainly there is nothing whatever in this last trial to show "that the Gibraltar shield is, as regards simply penetrative resistance, little inferior to a solid 12-inch plate." On the contrary, all the evidence unmistakably goes to prove the weakness of the laminated system, even as against "reduced" charges. And we should ask, how can our contemporary prove the laminated equal to the solid 12 inches, when a solid plate of that dimension has never been fired at? We have a right to infer the qualities of a solid plate from the trials of solid plates; but the equal strength of laminated platescan only be proved or disproved by positive experiments.

AIR-COMPRESSING ENGINE.

THE enormous difference of resistance in the air pump of an air-compressing engine from 0 (leaving out friction) at the commencement of the stroke to the full pressure a little before the end of the stroke, makes it extremely difficult to carry out the true principle of economy, viz., the expansion of steam. It has been proved by different experiments that expansion of steam cannot be carrie out successfully by engines already in use in compressing air above 7lb. per square inch. The object of the engine we have illustrated above, which is the patented invention of Mr. J. G. Lloyd, of Blaina, near Newport, Monmouthshire, is to equalize, or nearly so, the irregularity of resistance, so as to carry out expansion to almost any extent, and thereby effect great economy of fuel. The higher the degree of compression, the greater the economy. This engine, by means of the differential gearing, proportions the power to the resistance. The gearing is so arranged that whilst the driving shaft of a steam engine or any other motive power revolves at an even speed the piston of the air pump may, at the commencement of each stroke, move with a quicker motion than towards the end of the stroke. In our engraving, fig. 1 is a vertical section, and fig. 2 a plan of the machine. The air pump cylinder *a* is placed horizontally, and at one of its ends guides *b b* are formed, between which works a cross head *c*, which is connected to the piston rod *d* of the air pump cylinder *a*. At the opposite end of the air pump cylinder *a* is placed the cylinder *e* of the steam engine employed for giving motion to the piston of the air pump. The piston rod *f* of the steam engine cylinder *e* gives motion by a connecting rod to a shaft *g* placed above the end of the air pump cylinder, and on this shaft is a pinion g^1 gearing with a toothed wheel h^1 on an intermediate shaft *h*, on which there is fixed a differential toothed wheel *i* gearing with another similar wheel *k* on a third shaft *l* which is opposite the end of the air pump cylinder *a*. On this last shaft are cranks l^1 l^2, which by long connecting rods *m m* are connected with the ends of the cross head *c*, to which the piston rod *d* of the air pump cylinder *a* is attached.

By this arrangement the piston of the air pump will complete one stroke for each half revolution of the differential wheels *i* and *k*. These wheels are so formed as to give a quick motion to the piston of the air pump at the commencement of each stroke, and then gradually to reduce the speed of the piston until it has arrived at the point of the stroke at which the air in the cylinder will have been compressed to the same pressure as the pressure in the receiver into which the air is to be forced. The piston may then be caused to move with an uniform motion for the completion of the stroke. At the commencement of the following stroke the gearing will again commence to drive the piston at a quick speed.

The principle is equally applicable where other motive power engines are employed, such as turbines, waterwheels, &c., so that by the interposition of the differential toothed wheels between the driving power and the air pump the size and cost of the driving apparatus may be greatly reduced, and, of course, the consumption of water. The heat developed by compression is carried off by cold water contained in a tank surrounding the air-pump cylinder *a*, so that loss through that is not worth considering. The great utility of compressed air is becoming every day more apparent; it has advantages over steam in many instances, being at once a motive power and ventilator. It is particularly adapted for mining operations, such as tunneling, coal-cutting, &c. The success of compressed air at the Mont Cenis tunnel suggested to two enterprising French capitalists, MM. Biez Fils, and Galard Bearn, and to M. Sommeiller, the illustrious chief engineer of the works at Mont Cenis, to employ compressed air for distributing force from house to house as water and gas-light are now distributed, and even mechanical force, by means of Lenoir's engine.

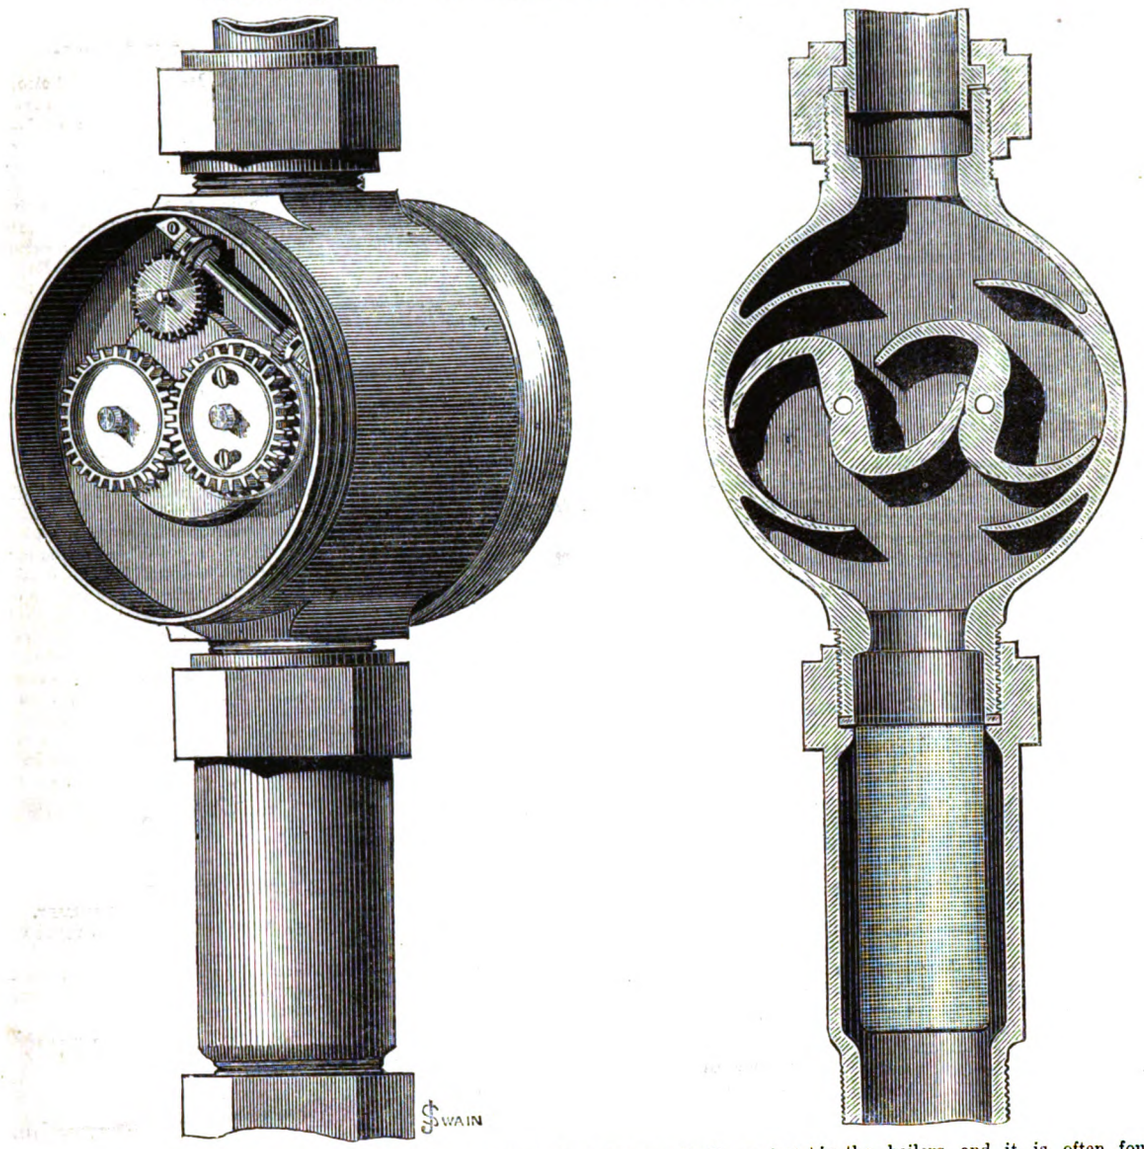
PAYTON'S CYCLOIDAL LIQUID METER.

CONSTRUCTED BY THE LIQUID METER COMPANY, LONDON.



PAYTON'S CYCLOIDAL LIQUID METER.

A SIMPLE, compact, and efficient water meter has long been wanted, and we appear at last to have found one in that illustrated in the above engraving. It is the invention of Mr. Walter Payton, and its action depends on the revolution of a pair of vanes, the interlocking surfaces of which are curved in prolonged epicycloids. The vanes, whatever be their position, divide the cylinder into two chambers, one in communication with the source and the other with the distribution. From the axes of these vanes motion is taken by appropriate gearing for moving the various counters on the index. The apparatus does not rely for exactitude of measure on fitting surfaces in contact amongst its parts, but on its extreme lightness and ease of motion, which, with the points of approximation of vanes and cylinder brought almost, but not actually, into contact, renders the passage of unregistered water practically impossible. In fact, from the absence of friction on the surfaces of the registering vanes, they move with such ease as to give no appreciable resistance, and, consequently, no measurable excess of water passing over that which is registered. These gauges were exhibited in Paris last year, and by experiments made upon them under the auspices of the "Conservatoire des Arts et Métiers" and vouched by M. Tresca and General Morin, we find that the excess of error in eight experiments, each extending over a period of from a quarter of an hour to an hour and forty minutes, and with heads of water ranging from about 12ft. to 40ft., the highest proportional error did not exceed ·034 per cent. It is stated that this arrangement acts well either as a pump or water motor. In this case, however, the leakage of water must be considerably greater than when employed as a meter, for there will then be a considerable difference in the hydrostatic pressure above and below the vanes, instead of that practically perfect equilibrium on which the action of the meters depends. In this matter, however, all rotary pumps and small water motors are under a similar disadvantage. The system will easily be recognzied by our readers as similar to that of Behren's rotary pump, Root's blower, and other contrivances of the same class, the difference lying in the shape given to the vanes, and the purpose to which the principle is applied. We may mention that the experiments in Paris proved that the fractional error to which the machine was liable sensibly diminished with an increase in the head of water, and an increase in the velocity of the vanes. The machine is at once simple and durable, and as there are no packed surfaces, a great source of derangement is avoided.

WOOD'S IMPROVED METHOD OF FITTING BOILER TUBES.

IN affixing cross or diagonal tubes in the flues of steam boilers great difficulty is experienced in getting them to their places, more particularly when the flues are finished and fixed in their places in the boilers, and it is often found absolutely impossible to take them out whole or to put new ones in a boiler which is completed or has been working without taking out the flues or using packing to make up the length of the cross or diagonal tubes, which latter method is obviously very objectionable and entails difficulty in making

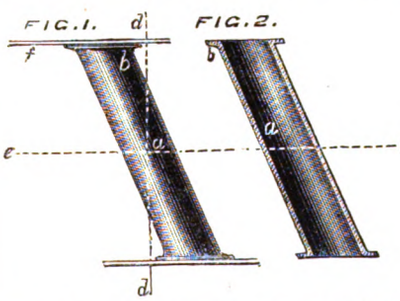


FIG. 3.

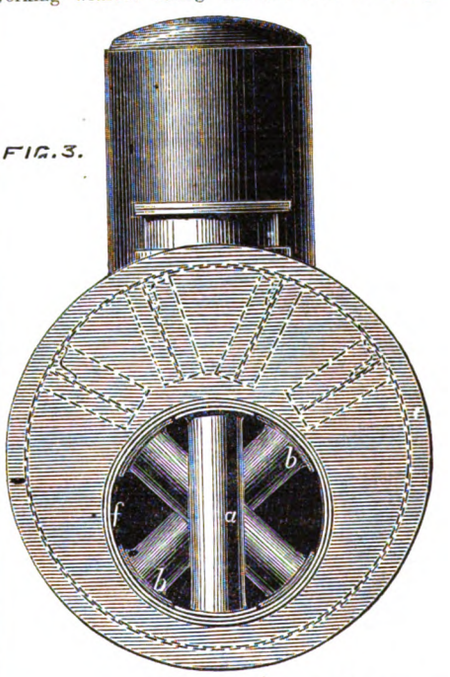

Digitized by Google

the ends of the cross or diagonal tubes properly tight. By the adoption of the system we are about to describe, all these difficulties may be obviated, as the cross or diagonal tubes may be readily fixed in the flue or fire-box of any boiler, whether vertical or otherwise, after such boiler be completed, or even when fixed on its seat ready for working without altering any part of its present construction or taking any part of it to pieces. This system has been patented by Messrs. Wood, of the Don Boiler Works, Sheffield, and is illustrated in the annexed engraving, in which fig. 1 shows a side elevation, and fig. 2 a longitudinal section of a flue tube; fig. 3 shows an end view of a single flue boiler with the improved tubes applied in position. *a a* is the water flue tube having a flange *b b* at either end, serving to connect the same to the boiler flue or fire-box. The ends *c c* of the tube, instead of being at right angles thereto, are made at an oblique angle to the centre line of the tube. In this manner the tube when placed in the flue will be in such position that a line *d d*, drawn through its centre from the edge of one flange to the opposite edge of the other flange, will be at about a right angle to the centre line *e e*, of the boiler flue *f*, or slightly inclining thereto in the same direction as the cross or diagonal tube. Tubes fitted in this manner possess the advantage of being readily passed into the flue, and of being fixed or removed at any time for the insertion of new tubes, without interfering with the flues in which they are placed whatever the kind of boiler in which they are applied. We hear that these tubes have been applied to several boilers now at work and which are giving every satisfaction. All the Cornish boilers now made by Messrs. Wood are fitted with them, three large boilers with thirty-four tubes having just been completed for one firm. Within the last three months they have been applied to five-and-twenty new boilers. The boilers fitted with the patent tubes and at work are reported to be effecting a saving of from 25 to 40 per cent. on the amount of coal required for the boilers they have replaced. In fact, this appears to be a most successful invention, and is one well worthy the attention of all steam power users.

SOCIETY OF ENGINEERS.

AT a meeting of the Society of Engineers, held on Monday evening last, Mr. Baldwin Latham, president, in the chair, the following paper, "On the Surveys of Proposed Lines for a Ship Canal Between the Atlantic and Pacific Oceans," by Dr. Cullen, was read:—

The necessity that has long existed for a short and direct passage from Europe and the United States to the western shores of America, Australasia, and China, and *vice versa*, by means of a continuous channel, which would obviate the necessity for transhipment, has given rise to several projects for the junction of the Atlantic and Pacific Oceans. These have been discussed in papers read before the Institution of Civil Engineers, by Mr. Glynn, in 1847, and before the Royal Geographical Society, by Captain (afterwards Admiral) Fitzroy, in 1850; but, since those gentlemen wrote, several surveys have been made and much additional information acquired. Early in 1867, a report on "Proposed Interoceanic Railroads and Canals" was presented to the Secretary of the Navy of the United States, by Rear-Admiral C. H. Davis, the Superintendent of the Naval Observatory, Washington, in accordance with a resolution passed by the Senate on the 19th of March 1866; but Admiral Davis has not entered into any detailed description of the lines, referring for information to the thirteen surveys and maps appended to his report. The following paper is, therefore, respectfully submitted with the view of giving a summary of all that is known on the question of interoceanic communication. All the proposed lines have been surveyed, except that of Darien, which will form the subject of another paper. They are from N.W. to S.E., the Tehuantepec, Honduras, Nicaragua, Chiriqui, Panama, Chepo, and Atrato.

THE TEHUANTEPEC LINE.

This, which is the most northern and western, attracted the attention of Cortes soon after the Conquest, from the narrowness of the isthmus and the remarkable depression of the Mexican table-land at that point. In 1771, the idea of opening a canal between the oceans by this route, which had long been entertained, received a sudden impulse from the unexpected discovery in the fort of San Juan de Ulloa, in Vera Cruz harbour, that some cannon cast at Manilla had crossed the isthmus by the rivers Chimalapa and Coatzacoalcos.

In 1774 the line was surved by Don Augustin Cramer, in 1824, by Don Tadeo Ortiz and Don Juan de Orbegoso; in 1842 and 1843, by Senor Moro; and in 1852, by Mr. Williams, on the part of the Tehuantepec Railway Company of New Orleans. On the 25th of February, 1842, Don José de Garay addressed a memorial to General Santa Anna, the President of Mexico, asking permission to cut a canal across the Isthmus of Tehuantepec, to unite the Gulf of Mexico and the Pacific Ocean. On the 1st of March, 1842, a privilege was granted to him, and immediately afterwards a survey was commenced at the expense and under the orders of Garay. The direction of it was confided to Don Gaëtano Moro, who was assisted by a large staff: from his work* and Garay's† the following appear to be the principal features of the route. The width of the isthmus from the mouth of the river Coatzacoalcos to to Tehuantepec, on the Pacific, is about 138 miles in a straight line, and the direction is nearly due south. The Coatzacoalcos falls into the Gulf of Mexico in lat. 18deg, 18min. N., long. 94deg. 17min. W., by two mouths. The principal entrance has a depth of 20ft. on the bar, and within the bar the depth is 6 to 7 fathoms, and the river is about 800 yards wide. Its course up to the confluence of the Malatengo is about 160 miles, with a fall of 132ft., the depth varying from 30ft. in the lower to 6ft. in the upper part of the river. Leaving the Coatzacoalcos ‡ and ascending the Malatengo and the Chichihua, the summit level is reached. This is not a peak or a ridge, but an elevated plain, called the Mesa, or table-land, of Tarifa, extending 35 miles in the direction of the proposed route. The elevation of this water-shed, or lowest summit level, is 685ft. From thence to the Pacific the distance is 35 miles, 15 of which are occupied by three lagoons, having a depth of from 12ft. to 18ft. The entire distance would be 210 miles, and the enormous number of 150 locks would be required. But Mr. Williams,‡ who, with Major Barnard, of the United States' Topographical Engineers, surveyed the line, gives it as his opinion that water does not exist at the requisite level in sufficient quantity to render a canal practicable by lockage, and the enormous length of rock which would require to be cut through precludes the possibility of adopting that alternative. To the above unfavourable features, it must be added that the adjacent coasts are frequently troubled with furious storms, called Nortes, Tapayaguas, or Papagayos, according as their direction is N., S.W., or N.E., and that there is no harbour of any kind on either coast. This line, moreover, is out of the way to any place, except California.

THE HONDURAS LINE.

This was explored in 1853 by Mr. Squier, for the Directors of the British Honduras Railway Company. It was (and is again) proposed to begin at Puerto Caballos (Port Cortes) in the Bay of Honduras, and to proceed directly south, through the state of Honduras, to Fonseca Bay, on the Pacific. Although the route has good harbours, and the head-waters of the Rio Goascoran and the Rio Humuya, one of the chief affluents of the Ulua, interlock and even pass by each other, in either direction, for several miles of their course, the construction of a canal is utterly impracticable, since the summit level to be attained is 2,956ft. above the level of the sea, and there would not be sufficient water to supply a canal. The length of the proposed railroad line is 231 miles, for 17 of which the grade is 95ft. per mile.

THE NICARAGUA LINE.

By this line it was proposed to effect a communication between the Atlantic and Pacific by deepening the River San Juan from its mouth to the Lake of Nicaragua, out of which it flows; and cutting a canal from the further side of the lake to the Pacific. The length of the San Juan, the mouth of which is in lat. 10deg. 56min. N., long. 83deg. 43min. W., is 119·08 miles. There are no cataracts or falls in it, all the obstructions being from rapids, the principal of which are those of Machuca, which extend for about a mile, with broken water running over a rocky bottom, and the Castillo and Toro rapids near the lake. It is at all times navigable along its entire course for large piraguas drawing from 3ft. to 4ft. of water. The fall from the lake to the Atlantic is little over 1 foot per mile. The lake is 95 miles long, and 30 miles wide, with an average depth of 15 fathoms. The elevation of its surface is 125ft. above the mean level of the oceans. Baily found the surface of the lake to be 121ft. 9in. above low water on the Atlantic, and 128ft. 3in. above low water on the Pacific Childs gives the elevation at 128·47ft. above low water on the Pacific. On the Pacific side of the lake there is a mountain ridge rising to a considerable height above it. From its crest there is a sudden descent to the Pacific, the nearest part of which is only fifteen geographical miles from the lake.

In 1781, Don Manuel Galisteo, by order of the Spanish Government, took the levels from the Gulf of Papagayos (parrots), on the Pacific, to the lake. He used a water level, and by a series of 347 stations, about 100 yards apart, found the height of the ridge intervening between the lake and the sea, upon the line he took, to be 133·3 feet above the surface of the lake. The distance was about fifteen geographical miles. In 1837 and 1838, a survey was made by Lieutenant John Baily, of the Royal Marines, at the request of General Morazan, then President of the Central American Republic. Mr. Baily* proposed to cut a canal 15⅝ miles in length from the lake to the port of San Juan del Sur. This little harbour is narrow at the entrance, but widens within. It is surrounded by high land, except from W.S.W. to W. by S.. The depth of water at the entrance is three fathoms, and its width 1,100 yards. Ships can go up for a mile and a-half, but as the winds often blow with great violence from the N.N.E., there is sometimes great difficulty in making the port. Baily found the summit level of the ridge intervening between the lake and the Pacific to be 615ft. or 487ft. above the lake. For a canal 30ft. deep and 50ft. wide, cutting through this ridge would render necessary the excavation of the enormous quantity of 4,927,577,800 cubic feet. Mr. Horatio Allen, the engineer of the Croton aqueduct, in whose hands Mr. L. Stephens placed Baily's survey, thought it would be preferable to rise by locks 72ft. from the lake, then to tunnel two miles through the ridge, and descend by locks to the Pacific. But, as the ridge is volcanic, there being four extinct volcanoes in it one of them, Omotepec, still smouldering, on an island in the lake, it was very reasonably apprehended that a sufficient supply of water could not be obtained for a canal at the elevation of 72ft. above the lake. On the whole, this line presents more formidable difficulties than Galisteo's.

CHILD'S SURVEY.

In 1850 and 1851, this route was surveyed by Colonel Childs for the American Atlantic and Pacific Ship Canal Company, his assistants being Messrs. Fay, Curry, Fitzgerald, and Cropsey. He proposed to cut a canal 28·28 miles long, with six locks, on the Atlantic side, and to canalize the San Juan by means of seven dams and eight locks The communication between the lake and Brito, on the Pacific, was to be effected by a canal 18·32 miles in length with fourteen locks The summit of the ridge to be cut through on the Pacific side was found to be 46·03ft. above the surface of the lake, and the width of the ridge to be eight miles. Some dredging would be required at either end of the lake, as well as piers and embankments, the approach to its shores being obstructed by shoals and sandbanks. At Brito an artificial harbour would be necessary. This line, the direction of which is westerly, would thus require seven dams and twenty-eight locks, and would consist of

Miles.	
29·29	of canal on the Atlantic side.
90·80	of river navigation.
56·50	of lake navigation.
18·32	of canal on the Pacific side
193.90	

Child's estimate for a canal 17 feet deep was £6.570,483. At the same rate a canal 20 feet deep would cost upwards of £10,000,000. He estimated the time necessary for the transit of a vessel from sea to sea at 77 hours, assuming that she would be in continual progres, day and night, and would only spend twenty-eight minutes at the passage of of each lock.

LINE BY LAKE MANAGUA.

To avoid the difficulty of cutting through the rocky ridge, it was proposed to carry the canal from the lake, by the River Panaloya or Tipitapa, to Lake Leon or Managua, and thence to descend to the port of Realejo on the Pacific. Lake Managua is, about 15 leagues in length, and 35 leagues in circumference, its greatest breadth being about 9 leagues. The average depth of water is 10 fathoms, and its surface is 28ft. 8in.

* Moro, Don Gaetano, Isthmus of Tehuantepec, 1846.
† Garay, Don José de, Isthmus of Tehuantepec, 1844.
‡ This Mexican word signifies a snake, and was probably meant to express the tortuous character of the river.

† Childs, Colonel O. W., Map and Profile of the Nicaragua Ship Canal Route, New York, 1852.

Digitized by Google

higher than that of the Lake of Nicaragua, with which it communicates by the River Tipitapa. It is, therefore, 157ft. 2in. above low water on the Pacific. The length of Tipitapa is 30 miles, and for a distance of 24 miles from the Lake of Nicaragua, it has a depth of from 1 to 3 fathoms; but beyond this there are rapids, and in a distance of 4½ miles, a fall of 13ft., caused by a dyke of recent lava. It could, therefore, only serve as a feeder for a canal. By this course the difficulties of getting over the ridge would be obviated, but the length of the navigation would be increased nearly 100 miles, and it is doubtful whether Lake Managua could furnish the water necessary for the lockage, in both directions, which it would have to supply.

OTHER BRANCH LINES PROPOSED.

It was also proposd to connect the N.W. end of the Lake of Nicaragua with the Gulf of Fonseca, or Conchalagua, the shortest line between them being more than 90 miles. Another plan was to make a cut from its S. end to the Gulf of Nicoya. By each of these modifications, however, the length of the canal, the amount of excavation and lockage required, and the cost, would be very considerably augmented. Lastly, Œrsted, a Danish engineer, proposed a line from the mouth of the Sapoa river, at the S.W. part of the lake, to Salinas Bay, and estimated the height of the ridge at 130ft. above the surface of the lake. This line would be altogether in Costa Rica. In 1858, Œrsted's line was surveyed by M. Thomè de Gamond, who ascertained the elevation of the Col de Salinas to be 130ft. above the surface of the lake. His report was published by M. Belly.* Early in 1859, M. Belly, M. Gamond, M. Élie de Beaumont, Mr. O'Gorman Mahon, and a large staff of assistant engineers, went out to survey the line for an association of French and English capitalists, but, after a careful examination, the project was pronounced to be impracticable.

Besides the unfavourable features of this route, the consideration of the insecurity of the works, if ever completed, would justify great hesitation in undertaking any extensive operations in this district. Earthquakes are of very frequent occurrence. Volcanoes have risen within very recent periods, and prodigious quantities of ashes, water, and lava have been from time to time thrown over the country; and the relative elevations of land and water have been materially changed, all within the memory of living men. Humboldt says, "there is no spot on the globe so full of volcanoes as this part of America, from the 11th to the 13th degree of latitude." Mr. Stephens describes several volcanoes now in a state of activity not far from the line the canal would take; and Baily relates a curious instance of the rise of a volcano to the height of 1,500ft. above the level of the sea from a spot where living men had milked cows. Indeed, the volcanic character of this country is officially recognized, for the arms of Nicaragua and the seal of the Government are five volcanoes in action. A new volcano burst forth near Leon on November 14, 1867, and continued to burn till the 30th, when it died away, apparently smothered by its accumulated eruptions.

The insalubrity of the climate, owing to the swampy character of the banks of the San Juan, is another disadvantage under which the route labours. On this point it may not be irrelevant to mention that, in 1779, an expedition was sent from Jamaica by Sir J. Dalling, to take the fort of San Juan on the river, and the cities of Granada and Leon, so as to command the lake. Lord Nelson, who was engaged in this expedition as captain of the "Hinchinbrook," in writing to Dr. Moseley, who was preparfng a second edition of his "Treatise on Tropical Diseases," remarks that, "in the 'Hinchinbrook,' with a complement of 200 men, 87 took to their beds in one night; and of the 200, 145 were buried in mine and Captain Collingwood's time, and, I believe, not more than 10 of that crew survived." On the return of the expedition, Nelson himself was carried ashore at Jamaica almost in a hopeless state.

Politically, there are, at present, no difficulties with regard to this route; but there was long a disputed boundary question, in which Nicaragua, Costa Rica, and the Mosquito territory were concerned. For many years, too, the occupancy of the mouth of the San Juan was a bone of contention between the British and United States' Governments, and a bewildering mass of diplomatic rubbish was written on the subject, which was, happily, brought to a close by the Bulwer and Clayton Treaty of 1850. But hardly was the ink dry when they disagreed about the meaning of the first few words of the first sentence, each interpreting them in a directly opposite sense, whereupon the distracting correspondence recommenced, and culminated in the burning of Greytown, or San Juan de Nicaragua, by Captain Hollins, of the United States' corvette "Cyane," on July 13, 1854. This act brought matters to a crisis, and the paltry and undignified squabble was at last settled by the Dallas-Clarendon Treaty of 1857.

The want of adequate harbourage on either coast is the grand disadvantage under which this route labours. Brito has no pretension whatever to be called a harbour, the line of the coast thereabouts not presenting even an indentation. The harbours at the other proposed termini on the Pacific are wanting in either capacity or security, or both. The so-called harbour of San Juan de Nicaragua, or Greytown, is formed by a broken, low peninsula, which forms with the coast an inlet or basin, about three-quarters of a mile in extent, at the mouth of the San Juan. This narrow strip of land is composed of loose, black, ferruginous sand, which is so highly magnetic as to interfere with the proper action of the compass. Outside of it a shoal extends to the distance of a quarter of a mile, over which the sea breaks heavily. Off Punta Arenas, the western point of this strip, there is a shoal with only three-quarters or half a fathom on it, which often shifts, and is subject to considerable changes, from the heavy floods that occasionally come down the river. Punta Arenas itself has of late years advanced so rapidly as to close the harbour, except to small vessels. In fact, this harbour is only the recipient of the waters of the San Juan, after they have passed through its delta, or percolated through the low grounds and out of the lagoons in the vicinity, bringing with them much drift bush and dead trees. These ground on the shoal off Punta Arenas, and become the nuclei of future islets, which, by their gradual increase, threaten to block up the harbour, and force the river to seek an outlet somewhere else. The delta, which is increasing, is formed, in the first instance, by mud brought down by the river. On this, dead trees ground and form islets, which in time become connected, the quick rank vegetation of the moist climate assisting in the process. The three channels into the river have only a depth of three-quarters or half a fathom over the shoal which extends in front of them, from the west extreme of Greytown towards Point Mandeville. Within them are from one and a-half to two fathoms in the river.

The West India Mail steamers and the New York steamers, which call at San Juan de Nicaragua, do not enter the harbour, but lay-to outside; and, as the prevalent winds make the coast a lee shore, they have to keep steam up all the time. Should it blow much, they cannot communicate with the shore, but are obliged to put to sea at once. Northers are not unfrequent, and much damage was done by one on the 22nd of November, 1862. Lieutenant (now Captain) Pim, R.N., who surveyed the harbour in April, 1860, says: "The deepest water I could obtain between the two points of the entrance was only 12 feet, and that not continuously across." On a subsequent visit he found that "the sand spit which forms the seaward face of the port had extended itself, and therefore narrowed the entrance, during 15 months, no less than 200 yards." More recent information is to the effect, that the harbour is almost completely filled up, and the river has forced a channel for itself elsewhere. It is evident that such a harbour could never be made suitable for the terminus of a ship canal. For this and the other reasons given above, the idea of opening a ship canal communication by this route has been finally abandoned.

For many years past, passengers and goods have been carried across by the Accessory Transit Company formed by Vanderbilt, of New York. They are conveyed by steamers and boats, on the lake, and mules from thence to the Pacific; and, although there are six transhipments on the way, the line is so frequented by outward and homeward bound Californians that it pays very well. A railroad from Monkey Point to Realejo has been proposed by Captain Pim, R.N. Monkey Point, 38 miles due N. of Greytown, is in lat. 11deg. 46min. N., long. 82deg. 45min. W. The little bay under its lee, which is protected by two islands, has good anchorage and an average depth of 3½ fathoms. The line runs close to the Chontales gold district. It length would be 225 miles. The lowest summit level, according to Mr. Collinson, C.E., is 619 feet above the lake, or 740ft. 9in. above low water of the Atlantic.

THE CHIRIQUI ROUTE.

This would lead from Chiriqui Lagoon, on the Atlantic, to Golfo Dolce, on the Pacific. The survey of the former by Captain (now Rear-Admiral) Barnett, R.N., proves that the former is an excellent harbour. Of Golfo Dolce, Commander Jeffers, U.S.N., the hydrographer of the Chiriqui Commission of 1860, says: "It is unsurpassed in natural facilities; three streams, the Golfito, Coisal, [and the Canaza enter the harbour, and afford an ample supply of fresh water." This line was examined, in 1848, by M. Hellert, a German traveller, who found that the supposed passage through the lofty range of mountains between the above ports presented the most formidable difficulties, and could in no way be considered practicable. In 1860, Lieutenant Morton, of the Chiriqui Commission, landed at Frenchman's Creek, in the Lagoon, explored a swamp of great extent, and discovered a hitherto unknown pass through the Cordillera. His examination resulted in the conviction that "it is entirely practicable to connect the harbours by a line of railroad." However, considering that immediately inland of the Lagoon, the Cordillera presents the summits of Cerro Robalo 7,012 feet high, the volcano of Chiriqui 7,001, and another 7,452 feet high, it is not probable that any pass exists sufficiently low for a canal.

This isthmus of Chiriqui is traversed from north to south by coal seams, varying in quality from lignites to semi-bituminous and semi-anthracite coals, which were first examined by M. Salomons, Mr. Wheelwright, and Sir Edward Parry. Mr. W. W. Ridley, civil engineer, of New York, who visited the district afterwards, says:—"Concerning the quantity of coal that can be obtained here, no doubt can be entertained that it is sufficient to supply the steamers on the Pacific for ages." Messrs. Shuman and Whiting, in their report dated April 1, 1851, on the coal formation of the island of Muerto, near David, on the Pacific, say:—"We have found the Muerto coal to burn equally as free as the very best English coal, emitting a bright beautiful flame, with as much bitumen." Dr. Lagarde, the surgeon of the French frigate "Obligado," which was sent to survey the Pacific coast of Veraguas,* brought specimens of the Muerto coal to Professor Rogers, of Pennsylvania, who, on analysis, found it to contain bitumen, 36·27; solid carbon, 58·48; ashes, 5·25.

On the Atlantic side, Dr. Evans, the geologist of the Chiriqui Commission, found a coal-field, extending from Secretary and Saddle Hills at Cape Valiente, for 50 miles in a N.W. direction, through Popa Island to the Changuinola river in Chiriqui Lagoon. Its breadth was from 5 to 14 miles, and the aggregate thickness of the seam of coal was 74ft. Dr. Evans deposited specimens in the Smithsonian Institution at Philadelphia. This coal-field is now worked by English and American companies for the supply of the Pacific steamers. Some years ago, a discovery was made at the village of Tarraba, in Costa Rica, of a bed of coal upwards of 6 miles in length and 150ft. in breadth. Dr. Evans also found in Chiriqui gold, and ores of iron, copper, and platinum. Although the entire of this line, with the exception of the Pacific terminus, is included within the territory of New Granada, the Government of Costa Rica granted a privilege for making a road along it to Mr. Silk Buckingham. This gave rise to a controversy between A. Montoya, Vice-Consul of New Granada, and E. Wallerstein, Consul-General of Costa Rica, and the privilege became null and void.†

(To be continued).

ON CRYSTALS CONTAINING FLUID.‡

By MR. J. B. DANCER, F.R.A.S.

THE author gave a brief history of the discovery of fluids in crystals, including Sir H. Davy's chemical experiments on the fluids and gases obtained from the cavities in quartz crystals; Sir David Brewster's discovery of the pressure cavities in the diamond, ruby, emerald, amethyst, chrysoberyl, &c.; the existence of minute crystals in these cavities and the two new and remarkable fluids, which are immiscible, but sometimes found together in the same cavity—one a liquid hydrocarbon, named Brewstoline, the other Cryptoline; his experiments and examinations of artifical crystals deposited from aqueous solutions; his examination of the Koh-i-noor diamond and others in the

East India Company's museum; and the geological speculations to which these discoveries gave rise. Mr. Dancer mentioned the experiments of his late father and others in producing artificial gems by intense heat, and stated that his own attention was drawn to this subject some twenty-four years since, by Sir David Brewster presenting him with a specimen of topaz containing fluid. Since that time he had examined a large number of crystals of various kinds, from the collections of friends, and had found fluid in quartz from South America, Norway, the Alps, Ireland, Snowdon, and the Isle of Man; and in fluor spar from Derbyshire; this latter specimen contained a considerable quantity of fluid, which burst the crystal of 180deg. temperature.* He suggested the employment of the microscope as a valuable assistance in detecting spurious from real gems; very few of the latter are perfect, and the flaws and cavities are so distinct in character from those which are so abundant generally in artificial gems that very little experience is sufficient for the purpose. This mode of testing of course is limited to transparent crystals, but might be employed when the usual methods are not practicable. He also mentioned Mr. Sorby's discovery of fluid cavities in the quartz of granite, in the quartz of volcanic rocks, and also in the felspar ejected from the crater of Vesuvius, and Mr. Sorby's method of determining the temperature at which various rocks and minerals are formed. At the conclusion of the meeting, crystals containing fluid were exhibited under the microscope, and the expansion of the fluid by elevating the temperature of the crystal whilst under examination.

THE LONDON ASSOCIATION OF FOREMEN ENGINEERS.

THE ordinary monthly meeting of members of this society took place on Saturday, the 1st, inst., at their rooms, Aldermanbury, City. The sitting commenced with the reinstallation, for the tenth consecutive year, of Mr. Joseph Newton as president. That gentleman, in resuming the office expressed his sense of the honour conferred upon him, and promised to devote his energies to the furtherance of the interests of the institution. The election of several new members—honorary and ordinary—followed. Among the former of these were Joseph Whitworth, Esq., L.L.D., F.R.S., John Lea, Esq., and W. F. Stanley, Esq.: and among the latter Mr. Peter Keay, of the Royal Arsenal, Woolwich, and Mr. Joseph Stone, of Messrs. Cottam and Co.'s.

Mr. William H. Keyte next proceeded to read a paper on the lining of large iron vessels or boilers with lead. The subject was treated in a thoroughly practical manner by the author, who detailed his own experiences in superintending works of the description in question. He had encountered many difficulties in the operations and found that it was almost impossible to overcome them. It was found that the vessels when charged with acid and heated beyond a certain degree showed symptons of weakness. The unequal expansion and contraction of the two metals induced a separation between them. The lining of lead, though applied in the first instance with great care, became permanently collapsed and distorted, and no means could be found for preventing that disaster. Illustrative of this fact Mr. Keyte introduced diagrams, exhibiting longitudinal and cross sections of a large boiler after being in use for a short time. The lead lining was seen to have become buckled and misshapen to an extraordinary extent, and to present other curious phenomena. The writer of the paper then invited his fellow-members to favour the meeting with their views as to the best way of solving the problem which had so far puzzled him.

Several members responded to the appeal, and numerous sketches were made on the spot and handed round for inspection. Some of these exhibited much ingenuity, and comprised a variety of plans for jointing the lead so as to facilitate expansion and contraction. The discussion demonstrated very forcibly the usefulness of the Association to the foremen and employers. It was sustained mainly by Messrs. Miles, Irvine, Fishwick, Bragg, Walker, Edmonds, Briggs, Stabler, and the president. Mr. Stabler very justly observed that in these days of gas and acid engines it was highly desirable for engineers to study chemistry as well as steam.

In putting to the meeting the customary vote of thanks to the contributor of the paper, Mr. Newton earnestly pressed the associated foremen to follow Mr. Keyte's example, and to produce subjects for consideration in constant succession. He wished to make the society an adult college for the promotion of technical, scientific, and practical knowledge. It was gratifying to be able to state that its proceedings were regarded with interest both at home and abroad, and he had it from Mr. Mackinlay, chief engineer of the Royal Dockyard, Bombay, and who had that evening started for India, that it was in contemplation to form a similar institution in Bombay. The vote of thanks having been unanimously passed, the sitting closed

* After this paper was written, Sir David Brewster informed the author that the fluid contained in crystals of fluor spar was water, and that the cavities burst at a temperature of 150deg.

Correspondence.

THE SQUARE OF THE CIRCLE, AND THE GREAT PYRAMID OF GIZEH.

LETTER IX.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—I really did not expect to have to defend my discovery of the square of the circle, and the ratio of the diameter to the circumference of a circle, against such a powerful body as the Royal Navy resident at Pembroke Dockyard; but I suppose I must do so in the person of your correspondent, "R. N.," who dates from there in your issue of January 17, 1868. The weapon, too, with which "R. N." assails my discoveries is so peculiarly naval, viz., "The Nautical Magazine" or "Approximate Ephimerides" of the heavenly bodies, that I should have thought "R. N." would not have advanced it without due thought and precision. Apparently, however, such is the case, for he does not seem to be aware that the paths of the planets, &c., are ellipses not circles; or what a powerful part the astronomical clock and its active young assistant the "chronographer," with other "thuribula" play in the department centered in the centre of Greenwich-park. He will perhaps inform himself, and become aware that the "Nautical Magazine" is not a fit weapon to use in the discussion of the question of the square content of a circle, or the ratio of the diameter of a circle to its circumference, and in a manner so "ex cathedra."

Reverting to the subject of the Great Pyramid of Gizeh, I think it will be better, before completing the elucidation of the internal structure of the Pyramid by diagram, to put before you and your readers some numbers and theories which may at first sight appear startling, but which, in this inquiring age, are worthy of discussion; and bearing relation, too, as they do, to the ideas and symbolisms of a long past age, clear up much which would otherwise be obscure. At all events, they will assist in rendering the internal description of the Pyramid afterwards from Colonel Vyse's measurements more lucid and easy.

In my last letter I alluded to Masoudi's account of the Great Pyramid and the objects of its builder. The store of astronomical and geometrical facts and instruments of which he writes was mainly confined to the Grand Gallery. This great depository of the recorded facts and learning of perhaps antediluvian age, speaking with reference to our common chronology, remained untouched, because undiscovered by the drunken epileptic and ruthless destroyer Cambyses, King of Persia, about 600 years before Christ, as well as by previous plunderers. It was not until, from a strong desire for learning, that at great expense the second son and successor of the celebrated Caliph Haroun Al Raschid, the highly cultivated and intellectual Caliph Al Mahmoun, succeeded, by the use of gunpowder, in obtaining access to its stores. This was nearly cotemporaneous with the wars of the Crusades, and I am confident that here was the source whence the Arabians derived their afterwards celebrated astronomical and astrological knowledge, as well as the arithmetical digits which are called the Arabian numerals to this day. I am equally convinced that the intellect and race which conceived and reared the Pyramids was not native Egyptian, but came from a distant source, which a fully reasoned orthographical and lingual search would lay bare, but which, I fear, your space will not enable me to do more than notice, if you will permit me, in a subsequent letter. At present, I will shortly state the objects of the Grand Gallery. Its length is filled on each side of the pathway (ascending from the entrance passage on a slope of 26deg. 18min. with the horizon) for about 21in. from the floor, by what are now bare sloping benches of stone, with twenty-eight equidistant broken holes termed ramp holes, and above these benches, on each side of the so-called roof of the gallery, are seven tablets of equal perpendicular width, but gradually narrowing in on each to the centre, over the whole length of the gallery. The twenty-eight ramp holes contained carved representations, now torn away, having reference to the appearance of the eastern and western sections of the celestial sphere during the sun's cycle of twenty-eight years. It is hence we derive the knowledge which guides us in the use and force of seven Dominical letters marking the dies solis or Sunday, which appear in our prayer-books and almanacks, originally derived from the Egyptian use of their seven planets in ruling over each day of the week of seven days, and over every hour of every day again encircling in the same gyration. The seven entablatures, the carved descriptions on which are now also torn away, recorded the positions of the seven planets during each of the twenty-eight years of the solar cycle. The highest entablature was dedicated to Saturn, the second to Jupiter, the third to Mars, the fourth (along which on each side of the gallery runs a groove which has been a sad puzzle to all Pyramidographers hitherto) to the Sun, the fifth to Venus, and the seventh and lowest to the Moon. Herodotus has long since, in his second book, "Euterpe," told us of the Egyptians valuing the number 12 as well as 7; and the Israelites derived a value of the same numbers from them; but he has not told us why this was, nor am I aware that the reason has ever yet been guessed at. But the Egyptians, or those who taught them, knew the powers of numbers better than any other nation; and the value of duodenary over denary arithmetic, which last is now in France, as well as elsewhere, so much the fashion, without due inquiry. The origin of the preference of the Egyptians for duodenary arithmetic was in the continued and endless gyration of their seven planets, to each of which the undernoted numbers were attached as follows:—

3 Saturn.	4 Jupiter.	5 Mars.	6 The Sun.	7 Venus.	8 Mercury.	9 The Moon.
9 The Moon.	8 Mercury.	7 Venus.	6 The Sun.	5 Mars.	4 Jupiter.	3 Saturn.
=12	=12	=12	=12	=12	=12	=12

The addition of these seven sums of 12 gives 84, which was the number of dactyls, fingers, or inches in the whole width of the Grand Gallery of the Pyramid. These inches were each 1-84th of the grand unit of measurement already mentioned (6ft. 10⅓in. British), and this unit is the longest and most natural human measure, viz., from the gaps of the first finger and thumb of the closed hands with the arms fully stretched down each side, the measuring line being extended from these points over the top of the head. This unit of measurement is still preserved nearly intact in the canna or reed of Naples and other standards of measure. This unit was first divided into seven parts, representing the measure over the top of the head from tip to tip of the ears; again, into the palm of four fingers and the hand of three fingers or inches. The multiplication of the two last divisions is the origin of and forms our own foot of twelve fingers or inches. The great human unit thus consisted of $1 + 7 + 4 + 3 = 84$. How near our own measures still are to these values may be tested by your readers for themselves, and the following two instances will exemplify the great convenience of this system of notation, viz. $7 \times 4 = 28 \times 3 = 84$, and $3 \times 4 = 12 \times 7 = 84$. It will be observed that the origin of all this is 7, and its constituent elements 4 and 3, and the first of these 4, which is the first square number, produces with 7 the second perfect number 28, which is the number of the solar cycle, while the number of the sun (6), is that of the side of the sun's magic square, and is also the first perfect number. With these two first perfect numbers all other perfect numbers terminate.

I must here bring Hutton to my side, or your readers will perhaps think I have embarked on the sea of imagination without a rudder. The following is from his Dictionary, under the heading "Magic Square." "The magic square was held in great veneration by the Egyptians. To Saturn they attributed the square of 9 places or cells, the side being 3, and the sum of the numbers in every row 15. The following table will explain:—

Planets.	Side of Square.	Places or cells in Square.	Sum of Numbers in each Row.
Saturn	3	9	15
Jupiter	4	16	34
Mars	5	25	65
The Sun	6	36	111
Venus	7	49	175
Mercury	8	64	260
The Moon	9	81	369

Finally, they attributed to imperfect matter the square "of four divisions, having two for its side, and to God the square of only one cell, the side of which is also an unit, which, multiplied by itself, undergoes no change."

I have shown in my last letter how the base of the Great Pyramid is restricted to 764ft. British by the circle of the sun's annual revolution, measured in Great Pyramid units; and although these magic squares of the Egyptians have been much derided, I shall presently show, as in the case of that of the sun, to which I shall confine myself, that they were really the expression and representation of true

Digitized by Google

astronomy. Before doing so I shall make a short quotation from "Hutton's Translation of Montucla's Edition of Ozanam's Recreations in Mathematics," newly edited by Edward Riddle, Master of the Mathematical School, Greenwich, in one vol., 8vo. London: Tegg, 1840. This is it:—"The sun is, or seems to be, a globe of fire, the diameter of which is equal almost to 111 times that of the earth; its surface, therefore, is 12,321 times greater than that of the earth." In writing this the author seems not to have observed that from want of due inquiry, he had, when treating of magic squares, overlooked the true meaning and value of the magic square of the sun. The base of the Great Pyramid is a comparison of the Pyramid, human, or earthly great unit of square surface with that of the surface of the sun, as just quoted. There are 111 pyramid or human units in 764ft. British, and 111 × 111 = 12,321. I now, then, produce the magic square of the sun's number:—

29	12	28	9	7	26
32	31	8	4	36	5
23	18	15	16	19	20
14	24	21	22	13	17
2	1	34	33	6	35
11	25	10	27	30	8

It will be seen that all these numbers vertically, laterally, and from corner to corner, give the number 111.

These suggestions are but a small portion of one branch of the derided and overlooked wisdom of the ancients, which may be drawn from the remnants we possess of their works duly weighed without prejudice, and with vigilant self-corrective search. I will not now continue them further, but I hope to do so in another branch of the internal teaching of the Great Pyramid in my next letter, in noticing the suggestions of Sir John Herschel respecting the star a Draconis, alluded to in my last letter.—I am, Sir, yours, &c., WILLIAM HARVEY.

London, January 29.

ANILINE BLACK.

SIR,—Can you inform me if Lightfoot's aniline black is applicable for dyeing woollen fabrics, and if a permanent colour, and, if so, where I can procure it; you allude to it in page 65 of your last number, under the "Notes on recent scientific discoveries and their practical applications."—I am, Sir, yours, &c., H. D. D.

[The colour can be printed on woollen as well as cotton fabrics, and will, no doubt, be equally permanent. We do not know Mr. Lightfoot's address, but think it is Accrington. Ed. M. M.]

INTENSITY OF COLD.

SIR,—There is a point in a subject of great importance to which philosophy has not hitherto paid that particular attention it deserves. This is the intensity of cold. In a theory of the universe the subject of cold is as important as that of heat. In the present position of the earth our knowledge is limited to a certain degree, beyond which it is impossible to advance. All that we know is, that the most intense cold we can experience approximates in its effect to that of heat. But, how insignificant are the degrees of cold to those of heat. As I said before, the position of the earth is the boundary of our knowledge. The physical impediment to our forming a correct opinion of the one as of the other is insurmountable. Arguing from the imperfect knowledge we possess, we may arrive at the conclusion that extreme heat and extreme cold are in effect the same, i.e., the decomposition of matter. The sun is a sufficient example; it is the source of heat As a planet increases its distance from its sun so must the cold increase in intensity, until, arrived at the confines of its system, it assumes that form which we behold in the central body of our own.—I am, Sir, yours, &c., H. SALOWAY.

6A, George-street, Dover-road.

WELL BORING IN ABYSSINIA.

SIR,—In your number of January 24, under head of Naval, Military and Gunnery items, you mention the fact of Captain Le Messurier having arrived at the Abyssinian camp with some "well borers" and a staff, and that the result has been highly satisfactory. Will you allow us to explain that the "well borers" mentioned are nothing more nor less than "Norton's Patent Tube Wells," noticed by you in the MECHANICS' MAGAZINE of December 13, 1867; and the beauty of the invention consists in the fact that these wells need no boring nor digging, but are simply driven into the earth where indications of water appear, and the result is produced. We may mention that we are now operating at Terling, in Essex, the seat of the present epidemic, where we have already founed a supply of good, clear water, though, at present, as we have only our small tube down, limited in quantity.—We are, Sir, yours, &c., G. C. WARDEN & Co.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

Meetings for the Week.

MON.—Society of Arts.—Dr. Letheby on "Adulterations of Food," at 8 p.m. Conclusion.

Royal Geographical Society.—Sir R. J. Marchison, Bart., President. Captain Sherard Osborn, R.N., on "The Exploration of the North Polar Region," at 8.30 p.m.

TUES.—The Institution of Civil Engineers.—Renewed discussion upon, 1st, "The Fresh Water Floods of Rivers:" and, 2nd, "Floods in the Nerbudda Valley"; and should time permit, the following paper will be read by W. J. M'Alpine, M.I.C.E., on "The Supporting Power of Piles, and on the Pneumatic Process of Driving Iron Columns," at 8 p.m.

Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

THURS.—Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

FRI.—Royal Institution.—Professor Roscoe on "Vanadium and its Compounds," at 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

DR. DEANE, Q.C., has been appointed Admiralty Advocate, in the place of Sir Travers Twiss, who resigned on his appointment as Queen's Advocate.

IT is expected that before the next monsoon, the Godavery river will be opened for navigation as far as the second barrier, 225 miles from the sea.

THE Liverpool, New York, and Philadelphia Steamship Company have contracted with Messrs. Tod and Macgregor, of Glasgow, for a new steamer, 345ft. keel and forerake, and about 2,600 tons measurement, to be called the "City of Brooklyn."

CAPTAIN PETON, commander of a Turkish steam frigate, the "Abdul Medjid," was recently fined £26 16s. by the Liverpool magistrates for illegally removing some cigars, wine, and brandy from the ship, which is now undergoing repairs in a graving dock. This is a grave case of smuggling.

PREPARATIONS are being made at Chatham Dockyard for the launch of the iron-clad frigate "Hercules," 14, 5,226 tons, 1,200-horse power, which will take place on Monday afternoon at about one o'clock. The gates of the dockyard will be thrown open some time before the launch, to enable the public to witness the ceremony.

MESSRS. KIRK, building contractors to the War Department in the Royal Arsenal, Woolwich, on Saturday last, commenced laying the foundations of the seven magazines ordered to be erected on the river bank in the Arsenal marsh. They are to be bombproof, and detached from each other by lofty mounds of earth, to guard against injury in case of accidental explosion. They are intended for filling and preparing live shells and 40-pounder gun cartridges.

A WAR DEPARTMENT circular has been received by Colonel Campbell, superintending the Royal Gun Factories at Woolwich, acceding to his request to be permitted to utilize some of the old cast-iron guns of small calibre, to be converted by the puddling process into bars and coils for the manufacture of the new Fraser guns recently adopted for the service.

A NARROW escape from a very serious fire breaking out at the Keyham Factory, Keyham yard, Devonport, took place last week. The major part of he men had left work, when some millwrights that twere employed extra hours discovered a large portion of the timber framework supporting the tramroad passing through the quadrangle a mass of smouldering fire, and on the point of breaking out into a very serious fire. Assistance was promptly obtained and the fire extinguished.

THE foundation stone of the new fort about to be erected on St. Catherine's Rock, Tenby, has been laid by Captain Clements, Royal Engineers, in the presence of a number of officers and others connected with the Pembrock dock garrison. The clearing and levelling of the apex of the rock in order that the foundations might be firmly laid had been going on for months past, and the fort buildings will be at once proceeded with.

THE Swedish brigantine "Cherubim," which was rescued from going ashore at Credan Head in the storm of the 18th inst., by the Milford steamer "Great Western," and brought safe into Waterford harbour, has been detained by the receiver of wreck, Mr. Delahunty, at the suit of the "Great Western," pending a writ from the Court of Admiralty for salvage claims. The captain (Thalberg) repudiated the claim, and two custom house officers are now in charge.

THE directors of the Peninsular and Oriental Steam Company have resolved to present a handsome gold chronometer, with a chronograph, worth 100 guineas, to Captain Kuhn, the commander of the corvette "Venita," of the Prussian Navy, as a token of gratitude for services rendered by him to the passengers and crew of their steamship "Singapore," after the wreck of that ill-fated vessel in August last. The chronometer, which is an excellent specimen of its branch of art, has been manufactured by Mr. Jones, of the Strand.

The following lectures will be delivered in the lecture theatre at the Royal Engineer establishment, Chatham, to the officers and men of the corps of Royal Engineers during the spring:—February 3, on Stress on Beams by Mr. W. C. Unwin; 6th, on Continous Web Girders, Mr. W. C. Unwin; 10th, on Braced Girders, Mr. W. C. Unwin; 13th, on Roofs, Mr. W. C. Unwin; March 17th and 24th, on the Acoustics of Buildings, by Mr. W. F. Barrett. A course of lectures on Iron will also be delivered during the session.

Miscellanea.

THE corn crop of California for 1867 exceeded the value of the gold product. 161 vessels laden with wheat were despatched to Europe.

WE read that the passenger cars on the Boston and Albany Railway are heated by steam. The steam pipes run under the seats, and effectually warm the cars.

AT a book sale in the United States, a short time since, a copy of John Eliot's Indian Bible fetched 300 dollars, and a Dibden edition of Milton fetched 1,500 dollars or £300 sterling.

THE Masonic brotherhood of Philadelphia are about to build a granite structure 250ft. long by 150ft. wide, with a tower 300ft. in height. A very tower of Babel, and which will cost nearly 1,000,000 dollars.

WE understand that proposals have been issued for the formation of a society to be composed of scholars who feel an interest in the writings of Homer and early Greek poetry, and to be called "The Homeric Society."

A FRENCH *restaurateur* in New York is about trying the experiment of introducing horse-flesh in that city as food. He says its rivalry may have the effect of reducing the present exorbitant price of beef.

THE Princess of Leuchtenberg has just sent as a present to the Mineralogical Society of St. Petersburg, on the occasion of her marriage, a collection of fossils which she had made in her various tours in Europe. The association, in return, has elected her to be an honorary member.

THE yield of gold and silver in the United States in 1866 is estimated at 80,000,000 dollars; in Mexico and South America, at 40,000,000 dollars; in Australia, at 61,000,000 dollars; in British America, at 10,000,000 dollars; in Siberia, at 16,500,000 dollars; and elsewhere at 7,000,000 dollars.

RICH deposits of gold, it was some time ago announced, had been discovered in Russian America. A despatch to the State Department reports that an assay had been made of the gold ore found there at San Francisco, and it yields at the rate of 13,000 dollars per ton.

LIGHTNING recently struck a windmill at Kerlard, France, and killed one of the men, who had his head in a measure split open. The electric fluid, after tearing the canvas sails to shreds, darted across to the lighthouse of Grognoy, 300 yards distant, and shattered the paratonnere.

A CURIOUS record of fires in London, their causes and their proportion to trades and professions and private houses, has been kept for the last thirty-three years, during which time 29,000 fires have occurred, and nearly 36,000 fire alarms have been given at the fire-engine stations.

Digitized by Google

DURING one week the number of foreign letters received at and despatched from New York are reported to have been as follows, viz.:—British letters, 65,439; German letters, 42,117; French letters, 24,369; and Belgian letters, 809. The number of letters between the West Indies, Australia, South Pacific, and China and New York by united steam ships was 32,308 during the same period.

THE ceremony of opening the Lewes and East Sussex Industrial Exhibition, which has been for a long time in progress, will be performed on Monday next, by Mr. J. G. Dodson, M.P. Products of industry and art will be brought together from various parts of East Sussex, the works chiefly of artizans in their leisure hours.

LAST week a large meeting of the Tynemouth Society took place. Messrs. Ransomes' crack ploughman, from Ipswich, and twenty north-country ploughmen competed for the honours, among whom was a farmer's son, John Moore, from near North Shields, who, in a masterly style, carried off the first prize with a Howard's plough. The society also gives a silver medal to Messrs. Howard as the makers of the first winning plough.

THE number of visitors at the South Kensington Museum during the week ending February 1 were:—On Monday, Tuesday, and Saturday (free), from ten a.m. to ten p.m., 7,406; Wednesday, Thursday, and Friday (admission 6d.), from ten a.m. till four p.m., 1,514—total, 8,920. Average of corresponding week in former years, 9,745. Total from the opening of the museum, 7,173,934.

A CIRCULAR from Mr. F. M. Page gives the particulars of the shipments of specie to the East during the last eight years, from 1860 to 1867 inclusive. The average has been £14,401,100. From the year 1860, when the amount was £13,500,372, there was an increase to £24,318,189 in 1864, the highest total ever reached, and from that point a decline took place, which assumed extraordinary features last year, when the exportation was only £3,659,154.

LAST week the gardener of Mr. John Brogden, in trenching some meadow land at Highbury, Middlesex, found a vase containing nearly 7,000 silver coins, consisting of silver pennies (London, York, Middlesex, Bristol, and Canterbury), groats, and half-groats, halfpennies, &c., (Irish and Scotch, Venetian and foreign, Teutonic), and two gold coins of Edward III., also an amber rosary. The coins have been partially arranged by Mr. Vaux, of the British Museum, previous to delivery to the Crown.

AN avalanche lately fell at four in the morning at Bareges, in the Hautes-Pyrenees. It came from the Turon de Venne by the Gavin Thell, and struck near the officers' quarters of the military hospital. The *debris* choked up the bed of the Bastan, and turned the stream into the principal street of Bareges, inundating a great number of houses, and tearing up the way to a depth of three feet. The inmates in many cases had difficulty in escaping with their clothes. The loss, not yet ascertained, is believed to be considerable.

AT a meeting of the members and associates of the Royal Academy, held last Friday evening, the following gentlemen were elected Associates:—Mr. Thomas Landseer, Mr. George D. Leslie, and Mr. William Q. Orchardson. Mr. Landseer, himself the son of a late Associate engraver, and the brother of two living Academicians, has been elected in the place of Mr. George T. Doo, one of the first line engravers of the English school, who recently retired; Mr. Leslie worthily sustains the name of his most distinguished father, Charles Robert Leslie; and Mr. Orchardson fitly represents the force of talent unaided by ancestral claims.

AT the last meeting of the Institution of Civil Engineers, twenty-two candidates were balloted for, and duly elected, including, as Members, Mr. J. W. Barry, Mr. James Craig, Mr. C. H. Denham, and Mr. D. R. Edgeworth; as Associates, Mr. F. B. Behr, Mr. Richard Broome, Mr. W. H. Cock, Mr. F. C. Danvers, Mr. E. W. De Rusett, Mr. C. W. Dixon, Mr. W. F. Faviell, Mr. A. F. J. Fisher, Mr. J. H. Greener, Captain John Tunstall Haverfield, R.M.L.I.; Captain W. R. Johnson, M.S.C.; Mr. J. O. Macdonald, Mr. T. B. Nelson, Mr. A. R. C. Selwyn, Mr. L. H. Shirley, Mr. A. T. Simpson, Mr. H. E. Thornton, and Mr. Thomas Walker. It was also announced that the Council had admitted as students of the Institution, J. H. Blake, Joseph Cash, Raymond Edmiston, Malcolm Graham, C. E. Jones, J. V. Ley, M. K. Peto, W. H. Peto, C. E. Robinson, A. T. Smith, E. H. Stone, and F. N. Thorowgood.

AT the general monthly meeting of the Royal Institution of Great Britain, held Monday, February 3, Sir Henry Holland, Bart., F.R.S., president, in the chair, A. T. F. Clay, Esq., the Rev. B. W. Gibsone, M.A., John Kymer, Esq., James Murray, Esq., and Mrs. S. Ralli were elected members. The special thanks of the members were returned to Mrs. Barlow for her seventh annual donation of £5 5*s*. The special thanks of the members were returned for the following additions to the donation fund for the promotion of experimental researches:—Alfred Davis, Esq. (2nd donation), £21; J. Garrick Moore, Esq. (5th annual donation), £10; John Peter Gassiot, Esq. 5th annual donation), £20; William Dell, Esq. 2nd donation), £5 5*s*.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1854, 1861
BUILDINGS AND BUILDING MATERIALS—1855, 1919
CHEMISTRY AND PHOTOGRAPHY—1845, 1886, 1888, 1900
CULTIVATION OF THE SOIL, including agricultural implements and machines—1829, 1842, 1883
ELECTRICAL APPARATUS—1856, 1917
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1862, 1864, 1871, 1877, 1887, 1889, 1895, 1896, 1897, 1901, 1906, 1909, 1913
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1844, 1884, 1893, 1915
GENERAL MACHINERY—1826, 1827, 1828, 1830, 1847, 1851, 1872, 1890, 1894, 1898, 1902, 1907, 1916
LIGHTING, HEATING, AND VENTILATING—1837, 1838, 1846, 1849, 1908, 1910
METALS, including apparatus for their manufacture—1833, 1905
MISCELLANEOUS—1832, 1834, 1836, 1841, 1843, 1850, 1853, 1857, 1860, 1863, 1866, 1868, 1869, 1874, 1875, 1876, 1880, 1882, 1885, 1891, 1899, 1914, 1918
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1859, 1867, 1878, 1879, 1903
SHIPS AND BOATS, including their fittings—1831, 1840, 1848
STEAM ENGINES—1839, 1865, 1892
WARFARE—1835, 1858, 1873, 1881, 1904

1826 A. M. CLARK. *Improvements in nippers.* (A communication.) Dated June 22, 1867.

The movable jaw of these nippers is secured to one end of a lever, the other end of which is acted upon by a toe attached to the inner end of the handle, so that a great leverage is effected, and the operation of the nippers in cutting wire, &c., facilitated.—Patent completed.

1827 S. HOLMAN. *Improvements in double-action pumps, part of which improvements are applicable to other reciprocating machines.* Dated June 22, 1867.

This invention consists, first, in making valve passages in the pump covers or ends of double action pumps in close proximity to the reciprocating piston or pistons, which pistons are solid pistons without valves. Second, in an extension of the foregoing arrangement whereby pumps of greater working capacity are obtained. Third, in an arrangement of pump whereby two pistons are attached to one rod, each piston having a valve which reciprocates in the cylinder with it; one valve is also fitted to each cover; as the pistons are reciprocated in the cylinder, the single valves in each cover, whether a suction valve or a delivery valve, will open alternately, and the valves in the pistons will open and shut corresponding to the opening and closing of the valves in the covers; one water passage only is cast on the barrel, and the water or other fluid is drawn into the pump, through an induction pipe between the pistons, and forced out through the pistons and through the valves in the covers. Fourth, in a simple method of operating the pump referred to in the third part of this invention. Fifth, in an arrangement of compound pump valves, the object being to permit these and other pumps to be worked at quick speeds with a minimum of concussion at the time of the opening and closing of the valves at every reverse of the stroke.—Patent completed.

1828 T. WILSON and W. HALL. *Improvements in machinery or apparatus for raising and forcing water and other fluids.* Dated June 22, 1867.

This invention relates to an eccentric rotary pump, applicable to the purposes to which ordinary centrifugal or steam pumps may be applied, and serviceable also as a fire engine. The patentees construct a cylindrical case of metal, through the ends of which there is fitted eccentrically a revolving spindle working in shifting boxes. On this spindle, inside the case, is a cylindrical disc of metal having grooves radiating from the centre. Within these grooves are fitted diaphragms or pistons of metal, and on the ends thereof are projections or studs furnished with anti-friction rollers, or not, such projections engaging in an annular groove made concentrically in the inner face of each of the ends of the cylindrical case. The backs of the diaphragms are recessed so that they work through or across each other, each piston sliding partly into the opposite groove or slot, whereby they are firmly supported in the cylindrical disc at all points of their rotation. The inlet and outlet passages are placed on opposite sides of the cylindrical case. On imparting a rotary motion to the spindle, the several diaphragms will be caused to rotate in the interior of the cylindrical case, and will be simultaneously caused to slide to and fro along their guiding grooves by the cam action of the annular concentric groove in the ends of the cylindrical case on the projections on the ends of the diaphragms, thereby keeping the outer edges of the latter in contact with the inner circumference of the cylindrical case.—Patent completed.

1829 J. SURRIDGE. *Improvements in anchors suitable for steam ploughs and implements.* Dated June 22, 1867.

In order that the anchor may be removed readily out of the ground preparatory to shifting it to another position, the shank and the flukes are not rigidly fixed the one to the other, but jointed, and wedges or locking instruments used to stiffen the joint whilst the anchor is required to resist the strain upon it; but which are withdrawn when it is desired that the anchor should draw out of the land. The inventor makes the shank of the anchor of a forked form with sufficient spread to render the anchor steady without requiring a stock. The two arms of the shank are slotted at their ends to receive the ends of the flukes; these are both on the same side of the shank, and are connected therewith by a bar passing through them, and also through the slotted ends of the shank; this bar thus both forms the axis for the flukes to turn upon, and serves as a stay between the arms of the shank. The inner ends of the flukes project a short distance through the slots in the shank, and a bar with wedge-formed ends drives in, in front of the inner extremities of the flukes, and between them and projections on the shank, and so the flukes are rendered fast, being wedged fast against the hinder ends of their slots. When the wedge locking bar is drawn out, a slight strain on the anchor draws the shank forward, and throws the flukes to such an inclination as to cause them to rise out of the land.—Patent abandoned.

1830 S. HALL and W. H. PARSONS. *Improvements in apparatus for moulding artificial fuel.* Dated June 22, 1867.

The patentees claim the combination of a moulding passage with a ram working to and fro in it, and a measuring chamber with a plunger working within it, which, for each stroke of the ram, supplies a measured quantity of material into the moulding chamber, as described.—Patent completed.

1831 J. L. V. LE MARQUIS DE COSENTINO. *Improvements in apparatus for obtaining motive power from rivers or streams of water, and for facilitating boats ascending and descending rivers or streams.* (A communication.) Dated June 22, 1867.

Here two parallel endless chains are extended between and gear with chain wheels on two horizontal axes at a distance apart from one another. The chains are connected to one another by rods which pass transversely across the space between the two chains, and these rods carry paddles or floats which project out at right angles from the chains. The running water, acting upon the paddles or floats, will give motion to the chains, and the power thus obtained may be employed in various ways, and for various purposes.—Patent abandoned.

1832 J. H. KEARNS. *A diary blotting pad.* Dated June 24, 1867.

This invention is not described apart from the drawings.—Patent completed.

1833 J. BIRCH. *Certain improvements in casting ingots of Bessemer or other steel.* Dated June 24, 1867.

This invention consists in suddenly cooling the upper surface of the molten steel when in the mould, and so forming a crust on the metal ready to receive the sand which is "wedged down" as usual, thereby dispensing ing with the iron plate ordinarily employed.—Patent abandoned.

1834 T. RAFFERTY and J. H. STOREY. *An improved apparatus to be employed in moving from place to place, laying down, and jointing metal pipes.* Dated June 24, 1867.

The patentees claim, first, the construction and employment of travellers of the form or forms, and for the purposes described, fitted with wheels, either with or without gearing for actuating the wheels, or any number thereof, the wheels being adapted to run upon rails laid upon each side of the trench in which the pipes are to be "laid," or being adapted to run upon a rail laid on one side of the trench, and upon a plank laid upon the other side of the trench, the traveller being fitted with the "tup," and for adjusting the height of the same. Second, the general construction and arrangement of the apparatus and of the lifting and other "tackle" attached thereto, or connected therewith, as described.—Patent completed.

1835 E. LEAHY. *Making cartridge cases.* Dated June 24, 1867.

Here each cartridge case with its swelled head and inner perforated chamber for holding the igniting material or percussion cap is formed all of one mass by compressing a piece of soft metal into a suitable die.—Patent abandoned.

1836 J. K. FIELD. *Improvements in the manufacture of candles.* Dated June 24, 1867.

The patentee claims, first, forming enlarged, conical, or tapering lower ends on candles by first casting the candle with a cylindrical or parallel enlargement, or with parallel projections, and then cutting such enlargement or projections to a conical or tapering form, with or without longitudinal, helical, or circular grooves upon it, as described. Second, forming candles with enlarged lower ends upon which longitudinal, helical, or circular grooves are cut, such grooves being made to increase in depth towards the lower end of the candle, as described. Third, cutting longitudinal, helical, or circular grooves upon the lower ends of the candles having no enlargement, as described.—Patent completed.

1837 E. P. GLEASON. *Improvements in cylindrical or Argand gas burners.* Dated June 24, 1867.

This invention consists in placing an adjustable deflecting point or surface immediately over or in front of the inlet aperture through which gas is supplied to the burner, and in duplicating its jet or flame openings.—Patent completed.

1838 L. C. F. CLERC. *Improvements in lamp burners for burning petroleum spirit.* Dated June 24, 1867.

Here the inventor employs a flat wick which passes up a tube, the upper part of which is elevated at such a distance above the reservoir of the lamp as will prevent too great a degree of heat being communicated to the liquid in the reservoir. At the upper part of the wick tube is a chamber, in which a quantity of the vapour is collected to maintain the flame; the spindle of the pinion for regulating the height of the wick is protected so as to prevent escape of vapour at that part. He connects a tube to the top part of the wick tube, through which the spindle of the pinion is passed, and in which such spindle closely fits. The upper part of the wick tube is removable, to afford facility for inserting the wick, and when in position fits closely, and prevents escape of vapour at that part. A gallery is used for supporting a globe or chimney, and a cap covers in the top of the wick tube when the lamp is not in use.—Patent abandoned.

1839 W. E. NEWTON. *Improvements in governors for marine engines.* (A communication.) Dated June 24, 1867.

This invention consists of two weighted rods suspended in opposite directions, and coupled together by cross rods which are, by connecting rods, coupled to the sleeve which regulates the opening of the throttle valve. These two weighted rods balance each other, as far as their weight is concerned; consequently, together, they are completely

Digitized by Google

independent of exterior force. To attain this end with greater facility, the top balls are made heavier than the lower ones, so as to balance the accessory weights, which move parallel with the axis of rotation. This arrangement of coupled weighted rods, possessing by rotary motion a considerable centrifugal force, becomes isochronized by the tension of a transverse spring attached directly to the arms, whereby its movement is constantly proportionate to that of the centrifugal force. These two weighted rods have crossed arms, because the isochronism caused by the transverse spring can neither be real, nor, in fact, exist when the resistance of the organ which acts upon the steam is produced on the hollow shaft or sliding collar, unless the movement of this resistance remains in every position of the balls in constant rotation to that of the centrifugal force, and of the tension of the springs. The invention is not fully described apart from the drawing.—Patent completed.

1840 R. CAPPER and G. READ. *An improved arrangement of ships' signal lights.* Dated June 24, 1867.

This invention relates to indicating by signal lights the course a ship is steering. The lantern at the mast head, or a screen or covering containing the mast head light, is fitted with coloured glasses corresponding to the port and starboard lights, and is connected (in any suitable way) with the steering wheel, tiller, or rudder, so that it may receive from the motion of the wheel or tiller an axial motion, and present to the distant spectator a colour corresponding to the light exhibited to him at the bow.—Patent abandoned.

1841 H. RUSHTON. *Improvements in the manufacture of artificial hair.* Dated June 24, 1867.

The patentee claims the use of wool, particularly that kind known as "Russian tops," or other similar wools or fibre, in the manufacture of artificial hair, in imitation of human hair; and also in the manufacture of crisped or curled hair for furniture, upholstery, &c.—Patent completed.

1842 H. R. J. DENTON. *Improvements in hay-making machines.* Dated June 24, 1867.

This invention consists, first, in substituting the trailing hay turners hereinafter described for the ordinary rotating fork turners; and, secondly, in so arranging the trailing hay turner that it can be adjusted according as the weight of the crop to be turned may require. The travelling hay turner is formed by connecting longitudinally, and transversely or diagonally, a number of large angular links of iron of a square or other shape; this flexible framework is suspended by a number of chains from a rotating bar fitted with a handle or lever for turning it, and with a toothed wheel and pawl for fixing it. This bar is fitted at the rear of a frame and shaft mounted upon travelling wheels, and linked angular frames, having their angles vertical, can, by the suspending chains and bar, be adjusted so as to clear the ground, or trail more or less upon it, according as the chains are let out, and thus, when drawn across the cut crop, will turn it over.—Patent abandoned.

1843 T. PEBARDY. *Improvements in surgical appendages, to consist of a corset and abdominal supporter combined.* Dated June 25, 1867.

This invention is too voluminous for insertion.—Patent abandoned.

1844 J. WILKINSON and W. GRIMSHAW. *Improvements in watches.* Dated June 25, 1867.

This invention relates more particularly to lever and flat watches, and consists of a novel arrangement of parts for dispensing with bars, fuzee, chain, maintaining power work, and fourth wheel and pinion.—Patent completed.

1845 J. WEBSTER. *A new metallic zinc paint.* Dated June 25, 1867.

The patentee takes spelter and melts it in a furnace, and raises it to 800 deg. Fah. He then covers the metal with a flux of borax mixed with caustic of soda or chloride of ammonia. He then adds about 7 or 8 per cent. of finely divided iron wire or scrap, agitating the whole with an iron rod until the whole of the iron or scrap particles are taken up by the zinc. He then adds sufficient antimony to cause the metal to run freely from the furnace. When the metal thus prepared has cooled down, it is next pulverized and ground, when it may be mixed with any oleaginous matter or varnish, and the metallic zinc paint results.—Patent completed.

1846 T. CROW. *Improvements in the manufacture of illuminating gas from gas tar oil or from gas tar.* Dated June 25, 1867.

The oil or gas tar (commonly called creosote or dead oil) is extracted from the gas tar in the usual way, and, when obtained, is placed in a tank or reservoir situated at such a height as to produce the degree of pressure required. From this tank the oil flows down through a pipe into a heated vessel or vaporizer. A continuous stream of the oil is allowed to flow over the bottom of the vaporizer only just sufficient in quantity to wet it, and in so doing it is instantly converted into vapour. The vapour so formed passes into a superheater which is maintained at a bright red heat. The outlet of the superheater must be sufficiently small in proportion to the generating capacity of the vaporizer, so as to maintain a constant accumulation of vapour, and consequent high state of pressure in the superheater. The vapour thus exposed simultaneously to a great heat and a high pressure is converted into permanent gas of great illuminating power, which can be dealt with as ordinary coal gas.—Patent completed.

1847 J. E. WHITING. *Improvements in apparatus for transmitting power or motion* Dated June 25, 1867.

This invention consists in means for extending the use of tension alone for transmitting power or motion, and is applicable for double-acting and rotary pumps, and for working other engines and machines where power or motion is required to be transmitted to a distance. The patentee provides two similar and corresponding cranks systems, each system having three or more cranks with their arms or throws projecting at right angles to the axis of that system, and so arranged as to divide the circle which the crank pins or their equivalents describe into equal parts. He connects the crank pins of one system with the corresponding crank pins of the other by rods, chains, or other appliances capable of exerting tensile force, taking care to make these connections equal as to effect.—Patent completed.

1848 F. HOOK. *Improvements in reefing and furling upper topsails.* Dated June 25, 1867.

The inventor supports, by stanchions secured to the lower topsail yard, a spar to which the foot of the upper topsail is made fast. The spar is free to rotate, and has at is arms grooves or spaces whereon the reefing tackle is wound during the furling of the sail. Furling is effected by raising the yard by halyards in the ordinary manner. The reefing tackle is led from the spar arms over sheaves on the lower yard, thence through blocks to the deck. To support the revolving spar he connects to the lower topsail yard one, two, or more sets of rollers carried in a jaw or jaws free to traverse round a certain distance, so that, on suddenly lowering the sail, the mouth or opening in each jaw, through which the sail passes, will take the same direction as the sail.—Patent abandoned.

1849 A. AITCHISON and T. SOUTH. *Improvements in means or apparatus for the production of gas for illuminating and other uses from hydrocarbons.* Dated June 25, 1867.

Here the hydrocarbon is conducted by a pipe from a reservoir into a retort which has a lump or lumps of fire clay adapted to receive sufficient heat to convert the hydrocarbon which is caused to fall thereon into gas. The vapour or gas thus generated, rising in the retort, passes through perforations in a surface of fire clay, &c., applied so as to become highly heated, and form surfaces towards the upper part of the retort, by the heat thereof to further heat the vapour or gas obtained, and which thence passes into the upper part of the retort, and is conveyed away to a purifying and storing apparatus for use.—Patent completed.

1850 L. BRUNETTI. *An improved process of embalming and preserving animal substances from decay, for anatomical purposes.* Dated June 25, 1867.

This process, which, though based on the principle of injection, leaves no trace of injection, includes three operations, namely, the preparation of the tissues, the tanning thereof, and their desiccation. The preparation consists in washing, the removal of fat, and the expulsion of the fluids employed for that purpose. The human or animal body is first washed, and the blood removed by injections of water in the excretory vessels and ducts, an aperture being provided for the escape of the water. The fat is then removed by the injection, first, of alcohol, and then of sulphuric ether; the ether is then expelled by injections, first of alcohol, and then by injections of water. For tanning the tissues, tannic acid is dissolved in boiling distilled water, and is then injected into the arteries, veins, or ducts. The desiccation is afterwards effected by heat applied internally and externally.—Patent abandoned.

1851 W. T. WATTS and D. J. FLEETWOOD. *Improvements in the manufacture of hollow vessels, and dished, sunken, or tubular shapes or forms in metal, or other material capable of being moulded.* Dated June 25, 1867.

This invention consists, firstly, in the use of water or other fluid as a mandril, core, cushion, or packing medium upon which to shape various forms in materials capable of being moulded. A cylindrical or hollow vessel or blank having been first produced by any suitable means, is fitted with a plug, hydraulic gland, and safety valve, the vessel being charged with water by preference. It is then subfected to the action or pressure of suitable tools, dies, or moulds applied externally, by which any desired shape or contour may be produced. Air may be used instead of water.—Patent completed.

1852 J. BUCKINGHAM. *An improved tool for opening metallic cases.* (A communication.) Dated June 25, 1867.

Provisional protection has not been granted for this invention.

1853 H. VEILLON. *Improvements in hot-air ovens for baking bread, biscuits, pastry, cooking, drying, or desiccating flour and other materials.* Dated June 25, 1867.

Here, as the interior of the chamber (or chambers) of the oven where the baking takes place does not communicate with the furnace for heating the same, no cinders, smoke, &c., can enter therein, and the baking proceeds continuously, as the heating and baking take place simultaneously.—Patent completed.

1854 G. ALSTON. *Improvements in the means of consuming smoke in furnaces and other fireplaces.* Dated June 25, 1867.

Here the inventor admits air on the top of the fuel above the fire bars from the front of the furnace, the draught being regulated by a damper at which the fuel is introduced. The ash pit is kept closed at all times, except when removing the cinders; the back of the furnace chamber is also closed by a plate or partition. In this manner the fresh air passes down through the fuel and fire bars, drawing with it the smoke and flame, and so effecting its almost entire combustion, the smoke afterwards passing away through the flues. The fire bars he makes of fire clay.—Patent abandoned.

1855 W. COOKE. *Improved apparatus for hoisting building materials.* Dated June 25, 1867.

This invention consists, principally, of a single fall or endless rope passing over a grooved pulley above, and having fixed, or connected to it, appliances for attaching two hods thereto, so that when the full one is being hoisted the employ one is descending.—Patent abandoned.

1856 M. F. MAURY. *Protecting submarine cables, when placed on board ship, and for facilitating the paying of them out.* Dated June 26, 1867.

This invention relates to submarine cables without any coating of hemp or wire for the deep sea, the shore ends in all cases being the same. Before putting such a cable on board ship the inventor divides it into sections consisting each of about twenty miles. Each section is coiled into a ball, and thus coiled it is packed into a watertight tank, which is then filled with water and sealed, leaving the two ends of the section on the outside, so that they may be got at for testing the cable.—Patent abandoned.

1857 T. TAYLOR. *New or improved implements or apparatus for playing games of skill and chance.* Dated June 26, 1867.

This apparatus consists of a table with recesses in the central portion thereof, upon which table are used pieces of ivory, &c., formed so as to slide easily along the surface of the table, to rebound freely from one another, and to fit the recesses. The pieces may be of a circular, diamond, heart, or other shape. The sides of the table are fitted with an elastic cushion, and a semicircular piece which forms the head has a similar cushion upon it, and is made so that it can be reversed to enable another person to play from the opposite end The pieces are struck with a flat circular-headed mace or hammer.—Patent abandoned.

1858 J. HUMAN. *Improvements in breech-loading cannon and firearms.* Dated June 26, 1867.

The patentee claims, first, the general form of the breech blocks, and the principle of their sliding axles, by which a portion of the forward block is made to enter the bore of the gun, and the rear block is also made to support and secure the forward block in its place; and also the arrangement by which both blocks fill the slot in the gun in a solid manner, as described. Secondly, using the rear breech block as a ram to force the forward block into and out of the bore of the gun, as described. Thirdly, the arrangement by which the faces of the breech blocks are planes at right angles to the axis of the bore of the gun, and by which the breech blocks are worked by hand spikes only, and without wedges, screws, levers, or other appliances, as described. Fourthly, the self-acting vent stopper working in combination with the rear breech block, as described.—Patent completed.

1859 R. EADIE. *Improvements in axles.* Dated June 26, 1867.

It is here proposed to cover the whole or a portion only of an ordinary forged iron axle with steel.—Patent abandoned.

1860 W. E. NEWTON. *Improvements in filtering apparatus* (A communication). Dated June 26, 1867.

The patentee claims, first, the introduction of the juice into the filter press from below, as set forth. Second, the use and application of certain movable pockets by which a continuous passage for the liquid to be filtered is formed, which passage serves for the double purpose of introducing the juice into the chambers, and drawing off what remains of juice when filtration is over or ceases, as set forth.—Patent completed.

1861 R. P. FORLONG. *Improvements in the means of consuming smoke in furnaces.* Dated June 26, 1867.

The inventor piles a number of pipes, made of refractory clay, upon the bridge of the furnace; the pipes are placed in the direction of the flue, and occupy the space between the bridge and the roof of the furnace, so that all smoke from the fire is forced to pass through the interstices between the pipes, which, from their proximity to the fire, are always red hot, and ensure the consumption of the greater part of the smoke passing through them. He also provides a pipe behind the bridge, immediately under the ends of the clay pipes farthest from the fire. This pipe passes over the bridge, and down on either side of the ends opening into the ash pit, immediately under the fire bars. The part of this pipe behind the bridge is perforated, and the hot air entering at the ends under the fire bars passes out at these perforations to ensure the combustion of the remaining smoke, and also improving the draught of the furnace.—Patent abandoned.

1862 W. B. GRAY and S. G. SINCLAIR. *Improvements in spinning and twisting machines.* Dated June 26, 1867.

This invention relates to the regulating of the tension of the thread or yarn during the filling of the bobbins, and consists in the use of a cylinder fixed on the builder rail. On this cylinder the bobbin is placed. The diameter of the cylinder is greater or less either in a part or parts of, or throughout, its length, so that the bobbin may fit upon it more or less closely, and thus increase or diminish the friction.—Patent abandoned.

1863 W. R. LAKE. *Improvements in churns.* (A communication.) Dated June 26, 1867.

This invention relates to the construction of a churn wherein the butter is produced by the combined action of revolving wings formed of wire gauze, and a series of obliquely arranged arms and paddles attached to a horizontal shaft. The arms and paddles are enclosed in a box, and the gauze wings are arranged within another parallel box with an aperture for the introduction of the milk, and communicating with the other box through an opening covered with wire gauze.—Patent completed.

1864 W. R. LAKE. *Improvements in cotton gins.* (A communication.) Dated June 26, 1867.

This invention consists, first, in the use of a pair of rollers in connection with a longitudinal bar or breast beam of such form that, when pressed up against the rollers, no more of the surfaces of the bar and rollers come in contact than is sufficient to hold the cotton while the comb is acting upon the seed of the cotton, the two rollers chiefly serving to feed the cotton forward. To provide a feed roll possessing great durability is the object of the second part of the invention, which consists in the use of a pair of clearing plates or clearers with teeth, and so connected with the stripping plate as to ensure their simultaneous operation. The stripping plate is braced to the upper "clearer" to stiffen the former, and prevent its being pressed away from the upper feed roll by the crowding of the cotton. The invention also consists in incorporating within the material of the upper feed roll emery, &c., or in employing wire or other metal strips in connection with the material of the roll, whereby great strength and durability are attained.—Patent completed.

1865 A. C. F. FRANKLIN. *Improvements in steam engines.* Dated June 26, 1867.

This invention is applicable where two cylinders are employed, the pistons of which are connected to one crank shaft (the number of the cylinders may, however, be more than two, or less than two), and consists in so arranging the engine that the steam only acts on each piston to move it in one direction, so that if two cylinders be employed, the pressure of the steam will be acting on the piston of one cylinder, and thus turning the crank shaft, whilst the piston or other cylinder is being moved back without being acted on by the pressure of the steam.—Patent completed.

1866 E. WHELE. *An improved method of gauging and cutting soap.* Dated June 27, 1867.

Here the inventor planes and gauges the bar of soap on two sides at right angles, so as to reduce them to one size, in such a way that a given length will weigh a given weight. He does this by placing the bars in a trough, and passing a plane or scraper over them; after this he takes a frame with a fixed knife standing upwards upon it, and by a lever he forces the soap against it, cutting it through to a given length; then using a slide and screw gauge for this purpose similar to the one now in use, and in cutting a second piece it pushes the first one before it, and so on in succession.—Patent abandoned.

1867 J. G. ROWE. *Improvements in railway signals, point apparatus, and lamps.* Dated June 27, 1867.

In one arrangement a series of levers (charged with detonators or fog signals) is arranged so as to move both longitudinally and transversely upon an iron bar or tube. This bar or tube has a linch pin driven through it, or stops placed at the side of it, to keep the levers in place, and the levers have key ways or slots in the boss when set for action; the outer ends of the levers rest on a stop bar, but when one of the signals has been exploded, an l

Digitized by Google

its lever is, consequently, not in a position to act, the latter falls into a vertical position, the key way or slot being then in a straight line with and clear of the linch pin or stops; the whole of the levers slide laterally a distance equal to the thickness of one lever, and hence the second lever takes the place of the first. The fog signals are placed on and taken off the metals (by the action of the ordinary signal wire) by a quick threaded screw and weighted lever, or by a winged pulley and spring, which impart a longitudinal to-and-fro motion to the first lever only of the series, and the whole of the levers receive lateral or transverse pressure by means of a weight or spring. The patentee employs a lamp so arranged in connection with a pyrometer, and other parts, that a fresh wick can be brought into use without personal attendance.—Patent completed.

1868 W. E. GEDGE. *An economical system of raising running waters by the simple use of the force produced by the current of a river or watercourse.* (A communication.) Dated June 27, 1867.

Provisional protection has not been granted for this invention.

1869 J. M'EWEN. *Improvements in the manufacture of roll tobacco, and in apparatus therefor.* Dated June 27, 1867.

One of these improvements consists in at once winding the tobacco so as not to require re-winding to form the roll. It is wound between two plates on a flat spindle or centre, which is afterwards withdrawn, and with this arrangement the ordinary pegging and binding can be dispensed with, whilst the central parts are better conditioned than with the ordinary method.—Patent abandoned.

1870 J. GARBOTT. *Improved machinery or apparatus to be employed in the manufacture of wire healds for looms for weaving.* Dated June 27, 1867.

The patentee prefers to use brass or copper wire for healds, which is placed on a creel, and thence wound on bobbins; the bobbins are then placed on spindles attached to the arms or rim of a wheel, through holes in which the end of wire is passed and received by a pair of draw rollers covered with flannel so as not to damage the wire. On motion being imparted to the wheel carrying the bobbins and wire, such wire is twisted or "doubled" together. A length of wire equal to the length of the heald having been drawn forwards and doubled, a bell, actuated from the wheel above mentioned, calls the attention of the operative, who inserts (between the wires at the point they come in contact with each other) a wire of larger diameter, which, on being withdrawn on the completion of the healds, forms the eye thereof. The length of twisted or doubled wire is cut, and the eye, in the centre of which is then placed a pin, and each end of such wire is received in the end of a hollow shaft through which is a hole and pin; each end is wrapped round the said pin, and on motion being imparted to the shafts and wire, the ends are wound thereon, forming a loop at each end of the heald, and afterwards a hollow tube of metal (answering the purpose of the ordinary heald staves) is passed through the loops; they are then complete.—Patent completed.

1871 W. BULLOUGH. *Improvements in looms for weaving.* Dated June 27, 1867.

This invention has for its object, first, the construction and application of mechanism to looms for weaving, and to the shuttles of such looms, whereby the motion of the loom is arrested when from any cause the weft thread is broken. Second, the construction and application of mechanism for the prevention of "floats" and breakage of warp threads.—Patent completed.

1872 J. and J. CASH. *An improved apparatus for winding bands or tapes.* Dated June 27, 1867.

This invention relates to the winding of surgical and other bandages. A cylindrical block of wood, &c., has a slit of sufficient width to admit of the insertion of a doubled part of the bandage or tape carried along its entire length, and inside and parallel to this slit a circular hole is formed having a greater diameter than the slit, which hole is also carried through the entire length of the block. The band is inserted double through the slot into the circular aperture; a peg is then inserted inside the doubled band, thus holding it, and enabling it to be wound easily upon the block.—Patent abandoned.

1873 E. FARRINGTON. *Improvements in breech-loading fire-arms, and in the manufacture of cartridges to be used therewith.* Dated June 27, 1867.

The chief object here is the construction of an improved arm with breech bolt and striking pin or needle, the percussion being produced by an ordinary hammer and lock. The improvements, in addition to the general action of the mechanism, and of the arrangement of the lock which is behind the breech, are the following:—First, the combination with a system of closing with a breech bolt and ordinary lock of a breech-piece screwed upon the barrel; this piece is provided with an inclined plane intended to draw back the plunger or rod which carries the needle; it also has a lump to withstand the blow of the hammer; also a hook and a tail-piece which weaken upon the stock the effects of the recoil. Second, the employment of a spring tenon, and having three objects, viz., to guide the bolt, to maintain it when closed, and to permit of withdrawing it by a quick tortuous movement without the aid of a special appliance. The invention further relates to the cartridges to be used with these arms, and the object is, chiefly, to produce hermetic closing of the joint at the breech, and of the passage for the needle, as well as to prevent the oxidation of the latter and the fouling of the chamber.—Patent abandoned.

1874 C. E. BROOMAN. *An improved regulating jupon.* (A communication.) Dated June 27, 1867.

This invention consists in the manufacture of jupons with tapes, strips, or bands, or some of them which can be lengthened or shortened, and the jupon thereby regulated.—Patent completed.

1875 W. E. NEWTON. *Improvements in apparatus for the manufacture of iced beverages.* (A communication.) Dated June 27, 1867.

This invention is designed to make iced soda creams. The apparatus is composed of a box made of marble, and contains, first, cans or compartments containing various syrups to be used in the manufacture of the iced beverages. Second, reservoirs for cooling the syrups, and the cylinders containing water charged with carbonic acid gas. Third, an arrangement of pusher and a cutter to chop up block ice and reduce it to powder. Fourth, a reservoir containing the cream. On the sides of the apparatus are arranged taps which communicate with the syrup cans; taps are also attached to the pipes communicating with the soda water cylinders.—Patent completed.

1876 M. H. TAYLOR. *Improvements in tuyeres for smiths' hearths.* Dated June 27, 1867.

Here the inventor proposes to employ a chamber set in the hearth, and into which the air is passed from the blowing apparatus. At one part of this chamber is an aperture through which the air issues to the fuel, and this aperture is capable of being closed by a valve mounted upon a spindle which is connected to a hand lever. The lower part of the chamber is provided with another aperture capable of being opened or closed by a valve, and allowing the passage of ashes from the said chamber.—Patent abandoned.

1877 W. HODGSON. *Improvements in screw-gill boxes for preparing wool and other fibrous substances.* Dated June 27, 1867.

This invention relates to retarding the drop of the fallers in screw-gilt boxes; also, to combining the said retarding apparatus with the dabbing brush (when such is used), whereby both may be operated simultaneously, and the one balance the other.—Patent abandoned.

1878 C. J. POWNALL. *Improvements in the means of communicating intelligence between parts of railway trains.* Dated June 27, 1867.

The inventor places a fast pulley on the guard's carriage, and a loose pulley on the carriage nearest the engine, or on the engine or tender. An elastic band is passed round these pulleys, whereby the motion of the one pulley is transmitted to the other, such band extending along the intervening carriages above the doors thereof, so as to be within reach of the passenger; or pulls may be attached to the band, and extend within reach of the passengers. An alarm, a bell, or acoustic signal is placed on or in the carriages which carry the aforesaid pulleys. In each carriage is a case containing a number of tickets bearing the number or indication of the carriage; some tickets are blank, and others bear inscriptions of such intelligence as would ordinarily have to be communicated. Clamps or hooks are provided for connecting the tickets with, or suspending them upon, the band. When a passenger desires to communicate with the guard, he calls his attention by drawing down the lower part of the band, thereby sounding his alarm.—Patent abandoned.

1879 W. R. LAKE. *An improved self-detaching coupling for railway carriages.* (A communication.) Dated June 27, 1867.

This invention relates to a coupling, the connecting pins of which are hinged to their supporting rods, which at the same time may be made to support the buffers. These rods are free to slide back and forth in guides, and they are held in position by springs, and the coupling pins have shoulders which catch under lips or slots so that the coupling pins will remain in an upright position, unless exposed to a lateral strain, and, consequently, the shackle bar is retained, and the carriages are kept from getting uncoupled as long as all the carriages remain on the track. But if one of the carriages runs off the track, whereby the coupling pins forming its connection with the succeeding carriage are subjected to a lateral strain, one or both of the coupling pins turn down, and the carriages become detached.—Patent completed.

1880 W. R. LAKE. *Improvements in metal ties or bands for securing bales of cotton or other substance.* (A communication.) Dated June 27, 1867.

Here a buckle is formed with an obliquely projecting central rib furnished on the outer edge with teeth or notches to hold one end of the hoop or band which is inserted through an opening in one bar of the buckle frame, the other end of the hoop being folded over a solid crossbar on the opposite side of the frame. The back or inner edge of the toothed rib is curved, to give greater strength to the buckle, and the open bar is formed with a shoulder to prevent the lateral displacement of the hoop.—Patent completed.

1881 J. R. COOPER. *Improvements in breech-loading fire-arms.* Dated June 27, 1867.

The patentee claims affixing the needle carrier or striker of the gun to an independent sliding block at the rear of the plug or closer, the block being provided with a projecting plate, whereby the needle or striker is cocked on the unfastening of the plug or closer, the block and plate, and parts immediately concerned in their action, being constructed and arranged as described. Secondly, combining or arranging the parts of a safety bolt for breech-loading firearms, as described.—Patent completed.

1882 W. DAVIS. *Improvements in the method of fastening the overlapping parts of envelopes.* Dated June 27, 1867.

The inventor provides each of the overlapping parts with one or more semicircular tongues projecting beyond the edge of the overlap. These tongues are partially severed by being cut through on each side to about one-fourth of their diameter, and in a line with the edge of the overlap. In the opposite or underlap of the envelope a transverse slit is cut of the length of the uncovered portion of the tongue, through which the tongue is passed, the severed portions being previously folded over towards each other. The folded parts being now opened out to their original form, the two laps are securely locked or dovetailed together.—Patent abandoned.

1883 L. B. ELLIOT. *An improved delivery to a reaping or mowing machine.* Dated June 28, 1867.

By this invention the inconvenience arising from the corn or grass which has been cut being spread over the uncut corn or grass adjacent to the course traversed by the machine upon the delivery platform being tilted, is avoided. This is effected by placing a board extending from one extremity of the finger bar in a diagonal direction across a portion of the delivery platform, such board being jointed at the upper part to a suitable support, the lower edge resting on the delivery platform, and being free to move therewith as the latter is raised or lowered by the attendant, in the ordinary manner. As the corn or grass accumulates upon the platform it is directed towards the side thereof opposite to that on which the board is placed, and from which the corn or grass can be delivered by the attendant.—Patent abandoned.

1884 W. MARSHALL. *Improvements in the construction and production of bedsteads, couches, or sofas, and other similar articles.* Dated June 28, 1867.

Here the laths form a surface in which the centre stands so much above the sides of the bedstead, couch, sofa, &c., that, when the weight of a person rests thereon, the surface of the article will become level, or nearly level, consequent upon the depression of the laths which support the weight of the person.—Patent completed.

1885 J. H. VITON. *An improved method of adjusting paper linings to the interior of casks, cases, and packages of various descriptions.* Dated June 28, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

1886 C. O. HEYL. *An improved method of and apparatus for making sulphuret of carbon.* Dated June 28, 1867.

This invention is not described apart from the drawings.—Patent completed.

1887 C. O. HEYL. *An improved method of and apparatus for extracting fatty matters from, and for scouring wool and other fibrous substances and textile fabrics, by the use of sulphuret of carbon, and for regaining the sulphuret used in such operation.* Dated June 28, 1867.

The inventor places the wool, &c., in closed vessels with or without steam jackets, and introduces the sulphuret of carbon from below; the sulphuret will pass up through the wool and issue near the top of the tank, whence it will pass through distilling apparatuses and return to its original receptacle. When the extraction is completed, he introduces a stream of hot water into the tank near the top, and so causes the volume of sulphuret with which the substance remains charged to fall to the bottom, and pass out of the tank to its original vessel. He then removes the wool, &c., and rinses it.—Patent abandoned.

1888 J. C. SELLARS. *Improvements in the utilization of a certain waste material obtained in the manufacture of hydro-carbon liquids.* Dated June 28, 1867.

This invention relates to the utilization of the pitchy or coke-like residue left in stills or vessels from petroleum, paraffin, &c., after the commercial hydrocarbons have been distilled over, and consists in manufacturing therefrom a substitute for plumbago, which the inventor denominates "artificial plumbago." He takes this residue and subjects it to heat in a retort, either with or without access of air, for a longer or shorter period, so as to drive off all the volatizable portions, &c. After this treatment the material is ready for use.—Patent abandoned.

1889 E. J. HUGHES. *Improvements in blankets used in machines for printing textile fabrics, and in the mode of joining together the ends of double-woven fabrics.* (A communication.) Dated June 28, 1867.

This invention relates, first, to the textile qualities of the fabrics used for the blanket, and to the finish of the same. The fabric consists of a single web of woven material, composed of a number of sets of stout but fine warps, generally of cotton, and a corresponding number of overlaying shoots of filling threads, of about the same fineness, and so closely interwoven as to produce about the same texture upon the surface as that of the generality of printing cloths or printing goods, and about the same thickness as the ordinary woollen blanket. After the blanket is woven it is subjected to a calendering process between heated rollers to remove all elasticity in the direction of its length, and sufficiently in regard to its thickness as to reduce the interwoven mass of threads to a merely compressible body that is not dependant upon the displacement of the threads of which it is composed, but upon the compressibility of the material thus fabricated, the material itself being intimately wrought together in one homogeneous mass or fabric. The invention consists, secondly, in cutting away one-half of the thickness of the warp and filling threads to about two inches of the two ends to be united, and from opposite sides of the two ends relatively one with the other, so that an equal thickness with the main part of the fabric will be produced by lapping the two half thicknesses of both ends one upon the other; the half thicknesses so produced present a ribbed or corrugated surface across the web, and when the ribs of one surface are closely fitted into and interlocked with the spaces between the ribs of the opposite surface, and then permanently fixed closely together, a means is afforded for resisting the strain lengthwise of the blanket that would tend to separate the two parts.—Patent abandoned.

1890 A. M. CLARK. *Improvements in presses for stamping or endorsing.* (A communication.) Dated June 28, 1867.

This invention is not described apart from the drawings.—Patent abandoned.

1891 G. K. GEYELIN. *Improvements in folding wire netting* Dated June 28, 1867.

To rings placed at convenient distances the inventor fastens a certain number of wires of given lengths by means of loops or hooks, so as to form a square, triangle, lozenge, or other figure, by which means the whole can be folded close together for movable poultry, sheep, and other fencings.—Patent abandoned.

1892 C. BROWN. *Improvements in actuating motive power engines, and in the apparatus or means employed therefor.* Dated June 28, 1867.

This invention is based upon a former patent, dated 28th February, 1867 (No. 558), and has for its object the application of atmospheric air, heated whilst under compression for driving motive power engines. The atmospheric air is compressed into a receiver or vessel, and when compressed it is heated by steam or otherwise. The increased expansibility of the air obtained from the elevation of its temperature constitutes the motive force, whilst the original compression at a normal temperature is a constant force in the receiver.—Patent completed.

1893 H. A. LYMAN. *Improvements in the construction of ladies' skirts.* (A communication.) Dated June 28, 1867.

These skirts will readily admit of being cleaned at or near the bottom edge. The skirt consists of an ordinary skeleton or other skirt extending from the waist downwards, some two-thirds, more or less, of the full length required for the complete skirt, to which is attached as a continuation a cloth skirt made with tucks or guides for steel hoops, which are intended to be withdrawn to allow of this lower part of the skirt being detached to be washed. The ends of the hoops are fitted, the one with a tubular slotted socket and the other with a cylindrical plug carrying a bayonet joint pin for attaching their ends together when the hoops are inserted in the skirt.—Patent abandoned.

1894 J. G. TONGUE. *An improvement in adjustable wrenches.* (A communication.) Dated June 28, 1867.

This invention relates to that description of wrenches for screwing up bolts or nuts, &c., in which a permanent jaw from the main bar is used in connection with a sliding jaw made adjustable by a milled head-screw, and consists, in combination with a ribbed or feathered construction of the main bar and swell or shoulder where it forms a back edge junction with the permanent jaw, of a peculiar recessed construction of the sliding jaw, whereby, while without adding materially to weight, increased strength

Digitized by Google

and stability are given to the wrench where it is usually liable to rupture, and the sliding and permanent jaws may be brought into the closest requisite position relatively to each other.—Patent completed.

1895 J. and T. ANDERSON. *An improvement in the harness of Jacquard engines.* Dated June 28, 1867.

This invention has reference to what is known as the "cumber board" in Jacquard engine harness. When the "set" is varied, a fresh cumber board is requisite with perforations of suitable pitch. To diminish this inconvenience is the object of this invention. In place of the ordinary cumber board the inventors use two boards, the one placed in the ordinary position, and the other a short distance above it, and they make such boards with a rectangular aperture in lieu of the perforations, and use adjustable strips which are passed transversely through the boards, and placed at such distances apart as may be requisite. They are thus enabled to alter the sets within a considerable range without displacing or removing the cumber boards, and have much convenience from the arrangement.—Patent abandoned,

1896 J. HOLROYD and W. FIELDHOUSE. *An improvement in twisting or doubling machinery for producing a certain species of yarn.* Dated June 28, 1867.

The object here is to produce twisted yarn of an uneven or irregular twist, such irregularities occurring at stated intervals. The patentees drive the lower roller of the twisting or doubling frame by what may be termed partial gearing, that is, by a wheel only partially toothed, the object of this being to cause the front lower roller to be stationary at certain periods, the flyers revolving at their accustomed speed, and the yarn which is being wrapped round that issued from the front rollers, and which is passed independently over the upper front rollers, being twisted more closely on what may be termed the internal thread during such temporary stoppage of the lower rollers, and producing a slack and a tight twist.—Patent completed.

1897 C. O. HEYL. *An improved method of and apparatus for extracting oil or fatty matter from cotton or woollen waste, and analogous substances, by means of sulphuret of carbon.* Dated June 29, 1867.

This invention cannot be satisfactorily described without drawings.—Patent abandoned.

1898 P. ZAROUBINE. *An improved sucking and forcing hydro-pneumatic pump with no piston.* Dated June 29, 1867.

The principle of this pump is the application of the properties of compressed and rarefied air for raising water without the aid of a piston, the degree of atmospheric pressure or expansion necessary for the purpose not depending on the variations of height to which it is desired to raise the liquid, which may be lifted from any depth.—Patent completed.

1899 P. SMITH. *Improvements in corking, stopping, and securing the contents of champagne and other bottles.* (A communication.) Dated June 29, 1867.

This invention consists, first, of a cap or cork cover of india-rubber, &c., placed over the cork and between it and the securing media for compensating for any porosity of the cork. Second, of a ring or collar of india-rubber, &c., passed over the cork and round the neck of the bottle, and under the cork cover; or this ring may be passed over the cork and rest upon the mouth of the bottle, to prevent any of the contents from escaping between the cork and the bottle. Third, of a metallic or other cap passed over the head of the cork, and enclosing the same, so that the lower edge of the cap either rests upon the bottle mouth, or presses upon the stopping ring, or encloses the bottle mouth and compresses the stopping ring between the interior of the cap and the exterior of the neck of the bottle; the cap being of metal hermetically seals the cork. Fourth, in the mode of securing the cap to the neck of the bottle.—Patent completed.

1900 A. M. FELL. *Improvements in purifying or preservative compounds to be applied to the fleeces or skins of sheep and other animals.* Dated June 29, 1867.

This invention consists in combining mineral oil obtained from coal, shale, or crude petroleum, and from which acids and alkaloids have been removed, with a saponaceous compound consisting of resin, palm oil, cod oil, soda ley, and potash ley, and with napthaline.—Patent abandoned.

1901 A. M. FELL. *Improvements in batching or treating jute.* Dated June 29, 1867.

This invention consists, principally, in the employment in the "batching" process of the mineral oil prepared by well-known processes from crude petroleum, or from the crude oil obtained from coal or shale by distillation at a low red heat, such crude oil being repeatedly treated with strong sulphuric acid, and with alkali, to remove alkaloids and acids, and being washed and distilled.—Patent abandoned.

1902 A. HODGE. *Improvements in adjustable appliances for fixing door handles.* Dated June 29, 1867.

This invention consists in adapting an internally screwed collar to screw upon the screwed edges of the square or equivalently-shaped spindle, such collar holding the handle by a flange or rim turned over a head or flange on the neck of the handle, and being prevented from unscrewing from friction against the door or shield by an interposed disc loose on the spindle, but fitted so as not to turn thereon.—Patent completed.

1903 H. J. COX. *Improvements in the manufacture of carriage bodies, and which said improvements are also applicable to the manufacture of pleasure and other boats, and other like purposes.* Dated June 29, 1867.

This invention consists in moulding carriage bodies, boats, and various other articles of coarse paper pulp, or pulp made and reduced from strong coarse fibrous material, using suitable adhesive or gelatin as material with the mould in a heated or cold state.—Patent abandoned.

1904 S., R., and W. TEBLOCK. *Improvements in breech-loading firearms.* Dated June 29, 1867.

This invention relates, first, to the small pin called the "striker," which, upon being struck by the hammer, explodes the cap of the central-fire cartridge, and consists in forming it with an enlarged head at its lower end, forming a double or single inclined plane or planes. A portion of the inclined plane or planes projects beyond the breech or back end, a spring being placed round the pin, and made to act in a downward direction, so as to prevent the end of the striker next the hammer from projecting over the level of the surrounding surface, except when the gun is loaded. When the pin is used in lock-tast guns, the inclined plane on the head need only be on the upper side thereof, so as to act whilst the breech is being closed after placing the cartridge in the barrel. In guns not on this principle the inclined plane on both sides is requisite in order to prevent the cartridge being held by the pin. This principle, when applied to the Snider gun, is accompanied by a further improvement, which constitutes the second part of this invention. By this improvement the gun is put on half cock at the same time that the cartridge is withdrawn. The invention comprises other features which we cannot give space to here.—Patent completed.

1905 W. H. RICHARDSON. *A certain improved mode of manufacturing iron and steel.* Dated June 29, 1867.

The patentee claims, first, the process of remelting pig iron and afterwards finishing it in a stationary revolving or reciprocating puddling, balling, or other furnace as an improved cast iron or crude steel, in contradistinction to taking the iron direct in the melted state from the blast furnace, and then converting it into improved cast iron or crude steel. Second, the process of manufacturing steel, as described, by remelting the pig iron in any of the furnaces set forth, in place of taking the iron direct from the blast furnace in a melted state, and then converting it into steel. Third, the application of the tubular rabble or stirring rod, or their equivalent, for injecting blast into molten cast iron in a revolving, reciprocating, or movable furnace, to enable the carrying out of the production therein of improved malleable iron, cast iron, or steel, in the manner described.—Patent completed.

1906 A. STEWART. *Improvements in textile fabrics, and in the apparatus or means employed for effecting the same.* Dated June 29, 1867.

This invention has for its object the production of certain figured appearances upon that class of goods known as fancy dress cloths, and it consists in a mode of printing some of the warp threads only.—Patent completed.

1907 J. J. LANE. *Improved machinery for making tapers.* Dated June 29 1867.

This invention relates, first, to machinery for coating cotton strands with wax or a composition for the manufacture of tapers; and, second, to the cutting up of the coated strands into lengths suitable for forming matches. We cannot here quote the details of the invention.—Patent abandoned.

1908 C. C. DUBRULLE. *Improvements in miners' lamps.* Dated June 29, 1867.

The principle of this lamp is that it cannot be opened without lowering the cotton or wick, and extinguishing the lamp if it had been lighted. For additional security the inventor provides the lamp with a second fastening, which prevents the removal of the wire gauze unless the fastening is opened by a particular key.—Patent abandoned.

1909 J. CONLONG. *Improvements in expanding and constructing combs or swaiths for warping, beaming, dressing, and other frames, and in machinery or apparatus connected therewith.* Dated June 29, 1867.

The object here is to obviate the defects of that class of expanding and contracting combs in which the dents are actuated by spiral or other springs, and are contracted or expanded by elongating or compressing such springs, and one part of the invention consists in substituting for those springs differential right and left-handed screws, acting independently on each dent by pins fitted into the dents, and fitting loosely in the threads, so that when the screws are turned a positive motion is conveyed to each dent separately; and another part of the invention consists in improved mechanism for cutting such differential screws.—Patent abandoned.

1910 C. PETIT. *Improvements in lamps for burning petroleum, shale, and other mineral oils.* Dated June 29, 1867.

This invention consists in forming the burners of lamps with their air chambers and passages much larger than those in general use, in order to burn not only shale and boghead oils, but also the lighter mineral oils, such as the oils of petroleum and others of a similar nature.—Patent completed.

1911 E. SEPHTON. *Improvements in the construction or arrangement of blocks, so called workmen's dwellings.* Dated June 29, 1867.

Provisional protection has not been granted for this invention.

1912 E. SIMMONS. *Improvements in the construction of screw propellers.* Dated June 29, 1867.

Provisional protection has not been granted for this invention.

1913 C. E. BROOMAN. *Improved means of applying and fixing metals on fabrics, feathers, artificial flowers, and other articles.* (A communication.) Dated June 29, 1867.

This invention consists, chiefly, in the use of a particular glutinous preparation for holding the gold, silver, &c., on the surface of the lace or other article. This preparation has two components or elements, viz., a solid material in powder, which is a mineral salt, by preference a salt of zinc (blanc de zinc), and a liquid substance which is a mixture of oil and varnish.—Patent abandoned.

1914 G. REES. *An improved method of treating glass in order to produce tablets and other articles.* Dated June 29, 1867.

Here the inventor takes glass in a state of powder, either dry or as a paste, and mixes the same, or not, with metallic or mineral oxides to produce various colours. He places this glass, either in the mixed state or not, in a mould having a design in or on its surface, or plain—if a plain surface is required—and after having filled the cavities, or covered the surface, if plain, he makes a backing to the required thickness of the same material (glass mixed or not); he then covers the material with a suitable cover, which may have indentations or projections upon it, and he presses these parts of the mould together with sufficient pressure to conglomerate the material between them. The material can then be removed from the mould and vitrified in a kiln.—Patent abandoned.

1915 J. G. N. ALLEYNE. *Improvements in clocks.* Dated July 1, 1867.

The patentee claims, first, the application to clocks of a combined pin wheel and gravity escapement arranged and operating substantially as described with reference to the drawings. Second, constructing the cams and ratchet wheels for clocks with the working surfaces formed of chilled cast iron, as described.—Patent completed.

1916 J. CHAUDRON. *Improvements in boring or sinking wells, and in apparatus and tools employed for that purpose.* Dated July 1, 1867.

This invention has for its object the sinking of deep wells through aqueous upper strata without having to pump the water out of the boring during the progress of the work, the apparatus employed being so arranged as to effect the complete isolation of the aqueous strata, thus enabling the work to be carried on through any depth of such strata.—Patent completed.

1917 F. T. HUBERT and H. D. G. TRUSCOTT. *Improvements in the construction of general electric telegraphic machines, and the mode of working them.* Dated July 1, 1867.

This invention relates to a former patent, dated June 28, 1866 (No. 1,725), and consists in combination with the mechanism of the indicator or dial therein described of the apparatus, hereinafter described, for printing either on a cylindrical or flat surface. The apparatus in its combined form consists of the mechanism connected with the dial—that for moving the cylindrical or flat surface as required to receive the printing, and that for bringing the same in contact with the printing wheel as required. The mechanism connected with the dial is or may be contained in a case at the upper part of the combined apparatus, and consists of the barrel, the rollers for inking the types, the printing wheel with types on it, such wheel being mounted as required at the back of the revolving dial indicator, and working through an opening which communicates with the apparatus below it; also the electro-magnets and springs, the electric commutators, levers, buttons, and handles required. The case underneath the above contains a movable cylinder covered with paper suitably arranged for printing, mounted so as to be capable of revolving and on its axis, and also of being moved horizontally to give the requisite spaces between the lines of the printing; and further, of being moved from the apparatus when required. The cylinder is turned by means of either one or two electric magnets with a lever escapement. After the cylinder has completed one revolution, it is moved horizontally through the space required by a lever escapement acting upon mechanism adapted for the purpose; the cylinder is raised and brought in contact with the type on the edge of the printing wheel, as required for each impression, by means of a set of multiplying levers which are actuated by the electro-magnets in the lower compartment of the apparatus. The cylinder is mounted at the two ends, so as to be capable of removal when the paper is covered with printing. The apparatus above described may be used either as a single electric indicator, or as an electric printing telegraph. The dial indicator with its apparatus is connected when required with the printing apparatus by means of an electric commutator at the lower part of the dial case.—Patent completed.

1918 F. T. POLLARD. *An improved bench dog or bench hook.* Dated July 1, 1867.

This invention is not described apart from the drawings.—Patent completed.

1919 P. IRONSIDE. *Improvements in the construction of Venetian blinds or shutters.* Dated July 1, 1867.

Here a vertical rod is laid in a groove, and each lath carries an arm which, besides passing through the vertical rod, rests in bearings formed in the sides of the groove. The vertical rod has a slot at its central part for each lath, and each lath receives a disc, eccentric, or plate, and through which each arm of each lath passes; pins also pass through the projecting points of each disc or eccentric; therefore, the arm of each lath is tied, as it were, in two places to the vertical rod; thus when motion is communicated to the vertical rod, whether causing it to rise or fall, so the discs turn the arms of the laths and alter the position thereof, as desired.—Patent completed.

PROVISIONAL PROTECTIONS.

Dated December 16, 1867.

3589 J. Stanfield, Betchworth, Surrey. Improvements in the means of and apparatus for obtaining and applying hydrogen gas to the furnaces of steam engines, boilers, and kilns for the manufacture of bricks and lime.

Dated December 21, 1867.

3635 C. G. Wilson, Regent's Park, civil engineer. Improvements in machinery for pressing cotton and other substances, the said machinery being adaptable for locomotion on railways or on common roads.

Dated January 1, 1868.

7 A. M. Clark, Chancery-lane. Improvements in breech-loading ordnance. (A communication.)

Dated January 3, 1868.

24 C. Long, Knightsbridge. A new or improved mode and apparatus for eliminating a portion of the azote in furnaces and fireplaces, and for utilizing the oxygen and hydrogen of water as facilitators of combustion, and as fuel, or as reducers, and in some cases as decarburators. (A communication.)

Dated January 4, 1868.

29 W. W Morley, Wooburn. Printing of paper bags while in the process of making by Shaw's patent, or other bag machines, or for printing paper from the reel.

Dated January 8, 1868.

73 W. H. Bailey, Salford, brass founder, and J. W. Lowther, Manchester, manufacturer. Improvements in lubricating tallow cups.

Dated January 9, 1868.

87 S. G. Archibald, Edinburgh. An improved mode of preparing tablets, paper, and other surfaces for receiving writing.

89 R. Winder, Farningham, engineer. A new folding machine for folding sheep, and in making temporary enclosures in place of hurdles, nettings, and other plans.

Dated January 11, 1868.

110 W. D. Young, Edinburgh, iron and wire fence manufacturer. Improvements in wedging and fastening fences and other similar structures.

Dated January 13, 1868.

119 C. A. Watkins, Greek-street, Soho-square, brush manufacturer. Improvements in the manufacture of ties for painting and other brushes.

Dated January 14, 1868.

120 T. Wood, Liverpool. Improvements in the construction of railway carriages, and in the method of coupling the same, as also in the method of, and apparatus for, signalling between passengers, guards, and engine drivers of trains, and officials and others at stations and other places.

122 C. D. Abel, Southampton-buildings, Chancery-lane. Improvements in the treatment of woven fabrics for improving the appearance thereof. (A communication.)

Dated January 15, 1868.

126 T. Sagar, machine maker, and T. Richmond, manufacturer, Burnley, Lancashire. Improvements in looms for weaving.

127 A. B. Boyer, Rue St. Lazare, Paris, doctor of medi-

Digitized by Google

cine. Improvements in the construction of aerial cradles.

128 F. and I. Alekan, jewellers, Boulevard Sebastopol, Paris. Improvements in studs for shirt fronts and other similar purposes.

129 W. E. Gedge, Wellington-street, Strand. The substitution of thin flexible and movable blades or cutters of sheet steel in lieu of rigid blades or cutters in planing machines, and machines cutting and shaping wood by means of rotating tools, and an arrangement which permits their use on tool holders or cutter stocks with curved, helicoidal, conical, and other surfaces. (A communication.)

130 L. M. Becker, Guildhall Chambers, Basinghall-street, City, telegraph engineer. Improvements in the mode of laying, supporting, and maintaining the wires used for electric telegraph and other purposes, parts of which improvements are applicable to other purposes.

131 G. Nimmo, Jersey City, New Jersey. An improved composition for furnace linings, fire bricks, pots, crucibles, and other articles.

132 J. Lang, Paisley, Renfrew. Improvements relating to the printing of music.

133 D. Hodgson, farmer, and J. Dodd, engineer, Swaton, Yorkshire. Improvements in machinery for cutting grass and corn.

134 J. Hudson, machine maker, and C. Catlow, overlooker, Burnley, Lancashire. Improvements in looms for weaving.

137 J. Parker, Glasgow, manufacturer. Improvements in textile fabrics.

138 J. Kidd, St. Paul's Wharf, London, engineer. Improvements in obtaining artificial light, and in apparatus employed therein.

139 J. Head, Newport Rolling Mills, near Middlesborough, engineer. Improvements in furnaces for puddling, boiling, melting, or heating iron or steel.

140 W. Wilkins and W. G. Pollard, hosiery manufacturers, Leicester. Improvements in the manufacture of knitted reversible gaiters and bootakins for children, and in mitts and armlets for ladies, gentlemen, or children.

Dated January 16, 1868.

141 T. Travis and W. H. Prince, silk spinners, and J. Tomlinson, machine maker, Rochdale. Improvements in machinery for clearing and smoothing yarn and thread.

142 J. Eggleton, Old Town, Clapham. Improvements in the manufacture of bellows regulators for waterclosets.

143 J. J. Ashworth, Manchester, manufacturer. Improvements in looms.

144 J. Tolson and J. Boothroyd, Dalton, Yorkshire. Improvements in mule spinning machinery.

145 R. Schneider, Manchester. Certain improvements in the manufacture of piled fabrics.

146 C. E. Brooman, patent agent, Fleet-street, City. Improvements in gas-heating and cooking apparatus. (A communication.)

147 H. B. and A. Mullord, manufacturing stationers, Hoxton. An improved material for the manufacture or ornamentation of bonnets and other articles.

148 J. Wood, East Wemyss, Fifeshire. Improvements in windows.

149 J. A. Jones, Middlesborough, engineer. Improvements in the manufacture of iron and steel.

150 W. Betts, Wharf-road, City-road, capsule manufacturer. A new manufacture of a material to be used in the production of capsules, and for other purposes where thin flexible metallic sheets are employed.

151 J. G. Rollins, Old Swan-lane, City. Improvements in baskets for containing fruit and other goods. (A communication.)

152 T. Nash, Great Dover-street, Surrey. Improvements in stoves and fireplaces.

153 G. E. Reading, Birmingham, manufacturer. Improved busk fasteners.

154 C. D. Abel, Southampton-buildings, Chancery-lane. A new or improved system of movable switches, tongues, or rails for the crossings and intersections of the permanent way of railways. (A communication.)

155 F. Postill, Nelson-street, Scarborough, brick manufacturer. Improvements in kilns for burning bricks, earthenware, and other ceramic articles.

156 W. E. Newton, Chancery-lane. Improved machinery for shaping, grinding, sharpening, and polishing sword blades and handles, scabbards, gun barrels, and other arms. (A communication.)

Dated January 17, 1868.

158 R. Heathfield, Birmingham, manufacturer. Improvements in machinery for the manufacture of nails and tacks. (A communication.)

159 J. Moorhouse, Wakefield, worsted spinner. Improvements in that class of machinery known as cone drawing, employed in drawing or preparing wool.

160 H. C. Lobnitz and A. Buquet, engineers, Renfrew. Improvements in apparatus for propelling ships or other vessels.

161 S. and E. Burrows, Dukinfield, Chester. Improvements in the method of employing waste steam and the water arising from the condensation thereof, and in apparatus connected therewith.

162 J. Hosking, jun., Gateshead-on-Tyne, engineer. Improvements in the cutting heads of instruments used in drilling, boring, tunnelling, or otherwise penetrating rock, stone, or other hard material.

163 J. Young, Stewarton, Ayrshire. Improvements in washing, and in the apparatus or means employed therefor.

164 H. Aitken, Falkirk. Improvements in treating iron ores or iron stones for the purpose of effecting economy in the obtainment of iron and other products therefrom.

165 J. Crossley, Halifax, carpet manufacturer. Improvements in washing printed and parti-coloured yarns.

166 J. M. Napiers, York-road, Lambeth. Improvements in apparatus for cutting and dressing metals, woods, and other materials, and in the tools to be used in combination therewith.

167 D. A. Fyfe, Edinburgh. An improved mode of manufacturing paper pulp from wood and other fibrous materials.

168 N. H. Rolfe, Hull, merchant. Improvements in machinery for cutting laths.

169 W. R. Lake, Southampton-buildings, Chancery-lane. An improved mode of treating wood-veneer, and forming therefrom sheets or cards for various purposes. (A communication.)

170 G. S. Fisher, Southampton-buildings, Chancery-lane. An improved implement for cutting hay, straw, and other like substances.

171 J. Winter, jun., Wardour-street, Soho. Improved apparatus for filling glass bottles and jars with soups, jellies, and fruits, for the purpose of preserving them, the said apparatus being also applicable for filling bottles with sauces, wines, spirits, beer, liquors, and other still and effervescing beverages, also machinery in combination with the above apparatus for corking or stoppering such said bottles and jars.

Dated January 18, 1868.

172 J. Millward, Cuzon Chambers, Paradise-street, Birmingham, civil engineer. Improvements in the means and apparatus or machinery for propelling ships or vessels. (A communication.)

173 T. B. Kay, engineer, and F. Hamilton, foreman, Bolton-le-Moors. Certain improvements in carding engines to be employed for carding cotton and other fibrous materials.

175 B. T. Moore, Elm Lodge, Spring-grove, Isleworth, Middlesex, civil engineer. A new or improved apparatus for protecting water pipes from injury by frost.

178 H. Kershaw, Laister Dyke, near Bradford, worsted spinner. Improvements in means or apparatus employed in spinning worsted and other fibres.

181 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in ribbon looms. (A communication.)

182 A. Bochkoltz, Vienna, civil engineer. An improved mechanical arrangement to be employed in connection with self-acting valves.

183 B. J. Heywood, Loraine-road, Holloway. Improvements in the manufacture of pencil cases.

184 J. Davidson, Woolwich. Improved machinery for manufacturing bullets.

185 W. E. Newton, Chancery-lane. Improvements in ovens or kilns for firing or baking porcelain and various kinds of earthenware or pottery. (A communication.)

186 J. Carr, Crescent, Clapham, and C. Lucop, Drummond-road, Surrey, manager. Improvements in the manufacture of meat and other biscuits.

187 G. S. Fisher, Southampton-buildings, Chancery-lane. Improvements in links or couplings for harness and other purposes.

188 F. J. Baynes, Holloway-terrace, Holloway-road, Islington. Improvements in kitchen ranges, which improvements are also applicable to other cooking stoves.

189 D. Timmins, Stourport, engineer. Improvements in motive power engines.

190 G. Gopsill, Birmingham, jeweller. Improvements in sleeve links and fastenings for articles of jewellery, and for other like purposes.

Dated January 20, 1868.

194 M. Robinson, Accrington, Lancashire, machinist. Improvements in the manufacture of expanding and contracting combs or reeds.

196 J. Woodley, Send, Surrey. Improvements in apparatus for communicating or signalling in railway trains.

200 J. H. Johnson, Lincoln's Inn-fields. Improvements in ships for containing oils or burning fluids, also in raising such oils or burning fluids, and supplying the same as fuel to the furnaces of steam ships, parts of which improvements are applicable to the ballasting of ships with water. (A communication.)

202 A. V. Newton, Chancery-lane. Improvements in sewing machines, parts of which are applicable to other purposes. (A communication.)

Dated January 21, 1868.

204 J. F. Spencer, Sunderland, engineer. Improvements in steam boilers.

206 C. W. Brown, Gloucester Villas, Upper Lewisham-road, New Cross. Improvements in the construction of truncheons used by police and other constables and persons.

208 C. R. Havell, Reading, Berkshire, artist. Improvements in water heating apparatus.

210 L. N. Le Gras, Wardour-street, Soho, civil engineer. Improvements in churns.

212 W. J. Coleman, St. Mary-at-Hill. Improved apparatus to be employed in the manufacture of beer and wine finings.

214 J. H. Johnson, Lincoln's Inn-fields. Improvements in apparatus for indicating the relative positions and movements of certain of the heavenly bodies. (A communication.)

216 W. Davis, Gainford, Durham. Improvements in the method of fastening bags made of paper or other material, for the conveyance by post, or otherwise, of samples of grain, seed, textile fabrics, and other articles.

218 H. Brinsmead, Ipswich, machinist. Improvements in thrashing machines.

220 A. B. Brown, Vauxhall Iron Works, Wandsworth-road, engineer. Improvements in actuating the valves of engines worked by steam or other fluid.

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," February 4, 1868.

2438 G. Haseltine. Iron and steel. (A communication.)
2668 A. Aitchison and H. J. Grantham. Carburetted gas.
2675 J. Griffin and F. Green. Envelopes.
2687 W. Winter. Sewing machines.
2688 G. Batcheldor. Trough waterclosets.
2690 J. H. Brown. Paper.
2692 T. H. Williams. Gas burners.
2703 A. Rooker. Taps.
2706 J. and J. Kirk, jun. Lace.
2713 J., B., and R. Wood. Steam engines.
2714 A. Morrall. Fish hooks.
2715 J. Jameson. Paper.
2716 G. Wilkinson. Pumps.
2719 J. Jameson. Indication of value on cheques.
2724 J. E. H. Andrew. Looms for weaving.
2728 A. M. Clark. Hat blocking machine. (A communication.)
2731 L. de la Peyrouse. Treatment of paraffin. (A communication.)
2732 F. Branscombe. Apparatus employed in drilling.
2733 J. and J. A. Huggett. Horse nails.
2736 H. A. Bonneville. Treating skins. (A communication.)
2744 M. Hamer. India-rubber tubing.
2750 I. Dimock. Apparatus for boiling eggs.
2751 W. J. and W. Hill. Securing watch chains to vests.
2752 J. Donald. Burning oil in furnaces.
2767 W. and S. Smith. Back rollers.
2779 W. R. Lake. Sewing boots and shoes. (Acommunication.)
2787 G. Townsend. Machine needles.
2800 R. Hattersley. Distributing printer's type.
2807 A. Bradburn and S. T. Marsh. Jointed rules.
2835 A. Danilecki. Electric baths. (A communication.)
2841 J. Speight. Spinning worsted.
2851 G. Twigg. Corkscrews.
2867 H. B. Barlow. Sewing machines. (A communication.)
2935 J. J. Holden. Polishing boots.
3065 E. Donner. Clearing skins.
3068 W. R. Lake. Cap for furniture springs. (A communication.)
3129 H. A. Bonneville. Preserving pasty matters. (A communication.)
3359 E. Belknap. Treatment of the solution of malt.
3381 E. H. Bentall. Nuts and bolts.
3424 J. Hadley. Drying corn.
3448 J. Newton. Lubricating parts of doffing knife apparatus.
3590 W. A. Gilbee. Raising water. (A communication.)
3632 J. Hadley. Cleaning grain.
3714 H. Bessemer. Treatment of cast iron.
19 E. J. and W. A. Kruss. Camera.
33 W. H. Atkinson. Cleansing casks.
69 S. Goldstein. Vest.
99 H. Cochrane. Making moulds for castings.
140 W. Wilkins and W. G. Pollard. Knitted reversible gaiters.
145 R. Schneider. Piled fabrics.
149 J. A. Jones. Iron and steel.
165 J. Crossley. Washing printed yarns.
184 J. Davidson. Bullets.
186 J. Carr. Meat biscuits.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed January 31, 1868.

2236 J. H. Johnson
2241 T. Allan
2242 J. G. Tongue
2244 J. and T. Elce
2245 C. D. Abel
2248 J. Russell
2249 A. Budenberg
2254 W. W. Hughes
2255 W. Wilson
2264 J. Heaton
2265 W. Prangley
2285 A. M. Clark
2291 T. J. Baker
2303 A. M. Clark
2325 H. M. Mellor
2369 J. W. Dixon and W. Buttery.
2508 G. A. Buchholz
2542 B. W. Ewer
2552 J. Marsden
2842 R. Smith
2860 W. H. May and P. Graham
2871 J. B. P. A. Thierry
3277 W. Anderson

Sealed February 4, 1868.

2259 W. J. Pughsley
2260 A. C. Bamlett
2262 J. G. Tongue
2267 T. Whittaker and M. Rourke
2270 T. Luthringer
2271 E. J. W. Parnacott
2276 C. M'Dermott
2278 F. C. Marshall and H. Stewart
2280 M. Hamer
2281 T. S. Cressey and J. Webb
2286 C. Benson and J. Barker
2297 C. Hohgrefe
2299 H. B. Barlow
2302 G. Hodgson
2304 G. Warsop
2307 F. H. Holmes
2329 J. Badger
2336 C. Holliday
2339 W. Betts
2340 W. Betts
2360 J. W. Dudley
2459 H. J. Simlick
2579 W. E. Newton
2972 W. Gray
3091 W. E. de Bourran
3093 J. Orr
3319 W. Boulton
3410 J. Fitter

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

210 T. Steel
244 J. H. Johnson
249 V. Burq
261 W. Teall and A. Naylor
281 J. and W. M'Naught
286 J. Hughes
292 C. Lungley
294 J. Ball
310 J. A. Phillips
319 R. M. Alloway
322 J. Booth
332 C. Beard

PATENTS ON WHICH THE STAMP DUTY OF £100 HAS BEEN PAID.

230 W. Winstanley, J. Kelly, W. Payne, and J. Formby
246 E. Smith
263 J. Chatterton
249 H. Phillips and J. Bannehr

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, FEBRUARY 14, 1868.

RECENT GUNNERY EXPERIMENTS AT SHOEBURYNESS.

SOME interesting experiments of a varied character were carried out at Shoeburyness at the close of last week. The first portion related to an improvement which has been made in the Dyer fuze, by Mr. Pettman, of the fuze department, Woolwich Arsenal. This Dyer fuze, which is also known by the name of the "C" percussion fuze, is extensively used in the service, a large quantity being always kept in store. They, however, possess a serious defect, which constantly shows itself in practice—they are liable to premature action. The fuze as originally constructed consists of a case with a solid head, in the centre of which is fixed a needle. Below it a cylindrical pellet is suspended by wire pins, having detonating composition at the top, and a chamber with mealed powder at the bottom. The case is closed by a plug, which screws in, leaving a space about the tenth of an inch between it and the pellet. When the gun is fired, the suspending pins are sheared, and the defect is, that the pellet falls frequently with such force against the bottom of the case, that it rebounds, striking the needle, and exploding the shell in the muzzle of the gun. Some time since Sir William Armstrong proposed to remedy this tendency by placing a leaden ring in the bottom of the pellet, which formed a cushion, and prevented rebound. Experiments were made with these improved fuzes, and the results were perfectly successful. But then the expense of this alteration is stated to be very considerable, as it necessitates the return of all the fuzes to the factory. Mr. Pettman has met the difficulty by placing a thin lead cup between the pellet and the bottom of the case. When the gun is fired the pellet falls upon this cup, flattening it down to a disc, and thus completely preventing rebound.

The advantage of this plan over that of Sir William Armstrong is that it does not involve the return of the fuzes to the arsenal, as the lead cup can be applied by simply opening the case and dropping it in. The alteration is, therefore, inexpensive, the cups costing only about five shillings per thousand, whilst they can be applied at any station. In the trials with the fuze thus improved, 50 were fired from a 12-pounder breech-loader field gun in loaded segment shells, plugged to burst on graze over water at 1,000 yards. The results of these were that forty-one burst on graze, three after graze, whilst six did not burst at all. Fifty more fuzes were then fired from a 9-pounder breech-loading gun in shells similar to those used for the first fifty. Six of these were fired over water, four of them bursting on graze, and two were blind. The remaining forty-four rounds were then fired to graze on sand at the same range. Of these shells thirty burst on graze, two after graze, and twelve did not burst. Eleven of the shells which did not burst were recovered from the range, and an examination of the fuzes showed that there were very good reasons for their not acting. In five the detonating composition was found to be defective, the needle having pierced the brass disc; in four the wires were not sheared; and in the other two instances the fuzes had acted, but were too feeble to pierce the cover over the burster. These experiments have therefore practically demonstrated the fact that Mr. Pettman has, by a very simple arrangement, satisfactorily overcome the liability of the Dyer fuze to premature explosion.

The second part of the experiments consisted of the testing of a trough in place of a tube for firing 9-pounder war rockets of the pattern known as Hale's. These 9-pounder rockets were formerly called 6-pounders, but the weight being nearer the first quantity their defining name has been changed. They are 16in. long, and have a diameter of 2·5in., outside measurement, their average weight being 8lb. 6oz. Formerly the cases were made of drawn tubing, which was liable to split, but now cases are made of sheet iron, riveted and brazed, with three corrugations pressed into it to secure the composition from giving way during flight. The Hale rockets have no stick, but rotate with a spin like a rifle bolt, through the action of the gas issuing from three perforations in the rear upon a small tail-piece or screw. These rockets made very creditable straight low tracks, thus redeeming the character of this missile, which has always been regarded as a very erratic weapon. It will be remembered that some experiments were made with rockets for the Abyssinian expedition; those we are about to describe were a continuation, and were made with the same class of rockets as are supplied to the expeditionary army. For the Abyssinian service it was found necessary to have tubes of short and small dimensions, such as could be carried by mules, and tubes of about 3in. in diameter were approved of. In the recent experiments a V-shaped trough 3ft. 5in. long, 3in. across, and weighing 16lb., was tried against a tube of like length 3in. in diameter, weighing 13lb. 4oz., with results decidedly in favour of the trough. Each was alternately fixed to the same light iron stand or four-legged horse, 16lb. in weight. A given number of rounds were fired from each under similar conditions, the particular advantages and disadvantages becoming apparent in the practice, which from the trough was most uniform. The tube requires a special friction tube for firing the rocket, whilst with the trough the ordinary service friction tube, as used for cannon, is found sufficient. It is a question, however, whether friction tubes will be found as useful as the old method of lighting the rockets by a port-fire, and for the reason that the tube is liable to rapid fouling, so that if the rocket jammed a burst would follow. Some time since a temporary apparatus was constructed at Shoeburyness, in which the trough was made to form, so to speak, one of the legs of a tripod. It was securely pinned to the ground at one end by a pivot, the two legs at the other end being hinged; the elevation for aim was got by opening or closing the hinged legs, as in the use of scissors. This arrangement appears to possess advantages over the present plan. The trials showed that 10deg. of elevation were as much as was practically useful, the composition having ceased to burn just before the rocket came to earth with the range thus obtained. The trough can be elevated with one end touching the ground, whilst the tube must be elevated some distance above it to permit the insertion of the rocket. The elements of superiority in the trough over the tube system are greater firmness in the stand, and less liability to be overturned in drawing the friction tube.

The results of the experiments will be seen from the following record of the actual practice made from the trough at 5deg. elevation, the right deflection being to windward. The total number of rockets fired was 22, the breeze being strong during the trials:—No. 1 round, range 541yds., direction in line; No. 2, range 546yds., deflection 6yds. right; No. 3, range 512yds., deflection 14yds. left; No. 4, range 60yds., grazed; No. 5, range 964yds., deflection 46yds. left; No. 6, range 260yds., deflection 1yd. right; No. 7, range 471yds., deflection 4yds. left; No. 8, range about 722yds., in water nearly in line; No. 9, range 539yds., deflection 5yds. right; No. 10, range 553yds., deflection 7yds. left. From the trough at 10deg. elevation:—No. 1 round, range 1,242yds., deflection 9yds. left; No. 2, range 570yds., deflection 44yds. left. From the tube at 5deg. elevation:—No. 1 round, range 886yds., deflection 13yds. left; No. 2, range 409yds., deflection 4yds. right; No. 3, range 767yds., deflection 11yds. right; No. 4, range 930yds., deflection 30yds. right; No. 5, range 669yds., deflection 26yds. left; No. 6, range 1,208yds., deflection 36yds. right; No. 7, range 668yds., deflection 4yds. right; No. 8, range 376yds., deflection 29yds. left; No. 9, range 850yds., deflection 69yds. left; No 10, range 181yds., deflection 6yds. left.

THE BATTLE OF THE SAFES.

THE battle of the safes bids fair to become as memorable as the battle of the guns and targets. Nor is it of less importance in its way. Guns and plates are for the protection of our country, safes for the protection of our cash. The one appeals to us as a nation, the other as individuals, and each with equal force. It is, therefore, no matter for wonder that the public should demand, and our manufacturers endeavour to supply, repositories for cash and other valuables, which shall be proof against thieves as well as fire. On the latter head we were tolerably well satisfied, but it remained for the Paris Exhibition to prove to us that we really had a safe which might really be considered as thiefproof. The burglary in Cornhill has not been without its fruits for good as well as for evil—evil as regards the loss sustained by Mr. Walker, but good as having led our safe makers competitively on to the production by one of them of an article which has proved itself worthy of the name of a "safe." The safe contest at the late Paris Exhibition, between Mr. Chatwood, of Bolton, and Mr. Herring, of New York, has been briefly referred to in our columns, but hitherto we have abstained from entering into detail particulars. Now, however, that we have the published report* of Mr. Robert Mallett, C.E., and Mr. Robert F. Fairlie, C.E.—the English members of the committee appointed to superintend the competitive trial of the two safes—upon the subject, we can no longer postpone the consideration of the details of the contest, which, in its results, placed Mr. Chatwood in the honourable position of victor.

From the report before us it appears that during the month of May, 1867, Mr. Silas C. Herring, a safe maker, of New York, affixed on the doors of his banker's safe in the Paris Exhibition a challenge against any other safe then exhibiting. Mr. Chatwood at once took it up, and proposed to test one of his safes, then in the Exhibition, against the one which had been so ostentatiously placarded, providing that burglars' appliances only were to be used. In July the agreement was duly signed by the respective competitors, and from which we quote the following:—"That, whereas the said Silas C. Herring is an exhibitor of safes in the Exposition, at Paris, and had on the 5th day of June, 1867, on one of the safes exhibited by him in Class 65, a certain challenge, setting forth that he the said S. C. Herring was willing to submit the said safe to a test against any other safe then exhibited by any other person." We are at a loss to conceive how language could have been more clear and explicit. And yet in the face of it, on the eve of the committee meeting in August, a month after the signing of the above agreement, Mr. Herring appends a codicil to his former posted challenge on the safe, intimating that "the small inside chest was only to be operated upon during trials," thereby ignoring the challenge safe and the original agreement. From this fact our readers will, no doubt, conclude with ourselves that Mr. Herring had not the implicit confidence in the security of the test safe which his challenge

* Tinsley Brothers, Catherine-street, Strand.

Digitized by Google

seemed to imply, and that he was desirous of stealing a march upon his English antagonist. We think the committee ought to have branded such an unwarrantable and clandestine proceeding as it deserved, by at once vetoing it, and doubtless the committee overstepped and exceeded its powers by allowing Mr. Herring to raise any question foreign to the original proposition as to which safe was meant.

The American proclivities of Mr. Hoyle, the secretary and interpreter to the committee, and the fact of the French chairman being entirely ignorant of the English language, made the American interest supreme in the committee, so that the influence of the English engineers was only as two to four; and on no other grounds can we account for the decision, that Mr. Chatwood should, in addition to opening the challenge safe, be compelled also to open the practically useless inside chest (into which a man's hat could be put), which Mr. Herring had adroitly attempted to substitute at the last moment. From the report we gather that Mr. Chatwood's men, when preparing their tools for the attack on Herring's challenge safe, had only provided for the siege such as may be strictly defined *bonâ fide* burglars' tools, and such as are ordinarily used by that fraternity. And, although Mr. Chatwood entered his decided protest against the committee overleaping the bounds of its authority (it being impossible to find this second safe within the agreement), he yet declared that so soon as he had fulfilled the well-defined stipulations of the original agreement, by throwing open the doors of the challenge safe, he would then be prepared to show that the practically useless inner chest embedded therein could be also opened. What shall be said, after this flagrant piece of Yankee smartness, of the committee in granting to Herring's men an advantage over Chatwood's in weight of tools, and this for the unique and simple reason that they declared the impossibility of opening Chatwood's safe unless they were permitted to use such appliances and instruments as are ordinarily required when a steam boiler has to be knocked to pieces, thus stultifying its own unanimously-recorded resolution, passed after critically examining the tools of the Chatwood party, thus, "That both competitors be allowed equal weight of tools." We think the committee were remiss in their duty in not on the instant giving the award to Mr. Chatwood, and handing to him the challenge stakes, instead of dallying with unreasonable demands which it had no authority to grant. It did, however, in the excess of its authority, allow to Herring the use of full-sized ponderous boiler maker's implements, more than double the weight of the tools which had been allowed to Chatwood, and the trials were allowed to proceed with these "dead weights" unjustly, as we think, hung upon Mr. Chatwood and his men. The extra sizes and weight of tools allowed by the committee to Herring's experts, during the operation, produced a result which forcibly reminded everyone present of the noise and clatter always found in a boiler maker's shop when in full operation.

It will, no doubt, be asked how comes it that the committee were so remiss in their duty as to permit such a disparity of tools to be used by the competitors? Does not the original agreement clearly define *bonâ fide* burglars' tools—such as burglars are known to use without being detected in their nefarious practices? Ergo, by what right did the committee permit Herring's operators to use tools nearly thrice as heavy as those used by Chatwood's men—tools, too, unknown in the burglar's nomenclature? The affair being in the hands of the committee, their primary duty was to have seen that the first conditions of the agreement were fully carried out. But, with all the extraneous and undue advantages granted to Mr. Herring, his men failed, and failed utterly, in all their efforts to open the invincible door of the Chatwood safe, and only succeeded in making a hole on one side by a battering ram and other heavy implements—(the total weight of which was above 242lb.)—in 235min. On the other hand, Mr. Chatwood's operators opened the doors of Herring's challenge safe in 29min. with the ordinary burglars' implements—(the weight of which was under 12lb.)—the additional small inner chest in the challenge safe taking 210min. further to open, the tools used being equal to 90lb. weight, making a total, in opening the two, of 239min. in time, and 102lb. weight in tools. We, therefore, come to the inevitable conclusion, from an examination of the proceedings of this great international contest, that Mr. Chatwood is really and truly the winner of the wager. We regret to find that, owing to the tampering with the chairman by the American members, and the secretary of the committee, the English engineers were compelled to retire on August 20 (the chairman having also resigned, in writing, at the same time), before any award had been made, or even discussed. Had a verdict been given according to the terms of the agreement, Mr. Chatwood must have been declared the winner, and would have had the satisfaction of distributing among the charities of London, Paris, and Washington, the £600 deposited by Mr. Herring, which, in addition to the £600 deposited by himself, the French stakeholder still retains in the imperial treasury of France. In conclusion, we would remind our readers that several years ago we prognosticated that "Mr. Chatwood's would rank as the foremost safe of its time." This prediction was signally fulfilled at Paris last year.

THE FORCE OF IMPACT.

THAT all moving loads or weights act with a certain amount of impactive or concussive force is now well established. Their action, so far as resulting from vertical descent, was never doubted, but the solution of the question was not equally apparent when the motion took place in a horizontal plane. This may arise from the fact that the effect in the latter instance is not so immediate a sequence of the cause as in the former. The one may be called direct, and the other indirect impact. Pile-driving presents one of the most familiar, and, at the same time, one of the fittest, illustrations of the force of direct impact. Although rules have been given for calculating the effect of the blow from a ram of a known weight falling through a certain height, yet they are practically of little value. This is due to the circumstance that the resistance is in reality an unknown quantity. It is never constant, and has to be assumed for each particular case. Nothing is more common in driving piles, than to find that one will go down nearly twice as fast as another placed only a few feet from it. When a discrepancy so considerable is found within an area so contracted, it is readily perceptible how erroneous any calculation must be which is based upon the assumption that the same description of substratum will invariably present a uniform resistance in different localities. The particular impactive force to which we at present intend calling attention, is that resulting from the motion of a weight in a horizontal plane, as its effects are not so obvious, although their occurrence is quite an every-day affair.

With the introduction of railways arose the necessity of bridges possessing greater spans, and correspondingly greater dimensions, than had been previously imagined. The difficulty experienced by engineers was very great in overcoming the fanciful fears and ominous anticipations of those who regarded the passage of a train as sudden death to any bridge of a large span. It must not be supposed that these ideas were entertained solely by unprofessional and ignorant persons. On the contrary, many first-rate mathematicians and others well skilled in the art of construction shared them, and persisted in the notion with a blind but rigid belief. At present we have no means of estimating the actual effect of the transit of a heavy train at a high velocity over a bridge. It is true that we can provide for the safety of the structure. We can assume the dynamical load to be represented by so many static pounds or tons, resting at different moments of its passage upon various portions of the supporting girders, and from these data deduce the strains upon the flanges and web, and allow, if necessary, an extra margin or proportion of material to resist any contingency which could not well be included in the theoretical investigations. Notwithstanding the sufficiency and accuracy of these calculations, we fail to obtain any value for the force, or that undefined impulse with which the moving load attacks, as it were, the structure. That it is compounded of the weight, and the velocity with which that weight moves, there is little doubt. The cause is known, but the actual manner in which it exercises its functions is completely unknown. It was this very uncertainty that occasioned the alarm when it was proposed to take a train across the Menai Straits, since it was assumed that the danger would augment enormously in the ratio of the span. Let us consider how far these suppositions were correct. In the first place, it is manifest that the resistance to a blow is in direct proportion to the weight of the object receiving it. The ordinary hammer and anvil are illustrations. The dynamical force, or, in this instance, the train, may be regarded as inflicting during its passage a rapid succession of violent blows upon the bridge, which resists them in the ratio of its own weight to that of the train. This circumstance was taken advantage of in rather a peculiar manner in the early days of railway bridges, an extra quantity of ballast being piled upon them to make them heavy. However effective in an anti-impactive sense this method might have been, the economy of the proceeding is undoubtedly open to question, but bearing in mind the excessive margin of strength allowed in the majority of the early girders, the additional load did not probably demand any especial increase of sectional area for itself.

Assuming, as is theoretically correct, that the resistance of a beam to the impactive action of a dynamical force is directly proportional to its weight, without any reference to its dimensions, the relation between a dynamical and a static force appears somewhat parodoxical. If we take two beams having exactly the same sectional area but different lengths, and make L = the length of the longer and L' that of the shorter, then their breaking weights under a static load will be as $\frac{L'}{L}$. But the same beams, when subjected to the action of a dynamical load, would have their breaking weight as $\frac{L}{L'}$. In the one instance, the shorter beam is the stronger; in the other, the longer. Either the weight or the velocity is constant in the above example, but one quantity may be varied. As a corroboration of the truth of the opinion entertained respecting the efficacy of increasing the dead weight of bridges, by the addition of an extra amount of ballast, the experiments of Mr. Hodgkinson may be quoted. That gentleman selected a number of cast-iron bars, having a sectional area of 9 square inches, and a length between bearings of 13¼ft. After breaking a certain number of them, and taking the mean of the results, he found that the height necessary to accomplish their fracture with a given weight was 2¼ft. In the second series of experiments the bars were uniformly loaded with weights, and the height necessary for the given weight to fall through, to break them at the

Digitized by Google

centre increased, as those weights were increased. When the bars were loaded with half their statical breaking weight, the height necessary for the given weight to fall through in order to break them was 5ft., or precisely double what was required when the bars were free from any load except their own weight. It must be borne in mind that the capabilities of the material with respect to deflection, have a great influence over its ultimate powers of resisting impact. A distinction must be drawn between the conditions of the examples we have alluded to, and those in which the material of which the beam or girder is composed, is presumed to become changed, with respect to its molecular constitution. This latter state may be brough about by the effect of long-continued impact. a subject which has been treated of by Mr, Fairbairn in the last series of his excellent work "Useful Information for Engineers." It is to be remarked in the experiments of Mr. Hodgkinson, that the greatest fall was required to produce fracture in the bars, before the static weights reached a proportion so high as that of one-half the breaking weight, so that there is evidently a maximum weight for each beam, to resist a given amount of impact. The determination of this ratio for girders and beams intended for railway bridges would not be without much practical interest and value. All these experiments, however, are only reliable up to a certain point. We do not consider that either in those instances we have adduced, or in the experiments carried out by Mr. Fairbairn and others, that the conditions accurately represent the action of the transit of a heavy train over a bridge. They are probably as close an approximation as can be obtained to the actual state of affairs, and must, after all, be viewed more in a theoretical and precautionary light. than in one which admits of a rigorously practical solution to the question.

NEW APPLICATION OF ELECTROTYPING.

WE understand that an ingenious American has invented a new kind of light summer hat, which will be introduced to the public in the next summer. The hat is to be made of manilla paper pulp. The advantages claimed for these hats are that they are exceedingly light, but nevertheless are waterproof. They are elastic, and will not be so liable to break as straw hats are. These hats are made to imitate straw-plait. The mode of manufacture is as follows:—Straw hats are made, by the ordinary process, of the various sizes and patterns required. These hats are then sized so as to be perfectly protected from the action of alkalies and acids. They are then blackleaded, and then copper wires are passed round them in various directions as electric conductors. The models thus prepared are then put into a bath of sulphate of copper, and a suitable battery attached: a one-cell Daniel's battery is sufficient, or even a one-cell Wolaston. When the deposit has attained about the hundredth of an inch, the wires that were wound round the model are detached in case they should have interfered with the deposit on the model. A connection is attached to the deposit in a suitable place, and the model is again immersed in the bath. When the deposit has attained a sufficient thickness to resist the pressure that has to be applied to it in moulding the hats, it is taken out of the bath, washed and dried, and the straw is then burnt out of the copper mould. The mould is then trimmed and put into a suitable frame, and it is ready for the moulding of the hats. The manilla pulp being prepared, it is pressed into the moulds. After being allowed to dry, the hat shrinks, and will easily leave the mould; it is then ready for sizing, waterproofing, and coloring according to the taste of the maker or the demand of the market. This is apparently a very simple and efficient manner of making hats, and it can be equally well applied to caps and bonnets, and will reduce the cost of these articles considerably, the material being cheap, and the process of manufacture simple and rapid after the moulds are made. There is one thing, however, which we would suggest to the inventor. In the electrolytic portion of his process we would recommend bronze powder instead of black-lead to produce a conducting surface on the mould. This could be applied before his insulating size is perfectly dry. If a beeswax size be used then the bronze powder could be applied at any time after the size is put on. Upon this bronze conducting surface the copper spreads much more rapidly than on blacklead. Electro-stereotypers find it much more effective and rapid; consequently, blacklead in electro-stereotyping has all but gone out of use. We think this new application of paper for coverings for the head will prove a great boon to the public, giving a durable and cheap article of dress. If we go on extending the use of paper as we have been doing we shall soon rival the Japanese in the use of that article, and we do not think that even they have reached the limits of its usefulness.

STEAM LIFEBOAT CUTTERS.

IN the steam launches which are now being supplied to our navy, the engine and boiler are not fixtures, but have to be hoisted out of the boat before it can be taken on board ship. In like manner, in getting the launch out of the ship, the boat is hoisted out first, and the engine and boiler are afterwards lowered into her. A considerable period must therefore elapse between the hoisting the launch out of the ship and the time of her steaming away. This defect, which, in some cases might prove of serious moment, is overcome in a very clever way in the steam lifeboat cutters which have been designed by Mr. J. S. White, of East Cowes, and which are being adopted by our naval authorities. The way in which Mr. White obviates the loss of time that now occurs between the services of a boat being called into sudden requisition and her leaving the ship under steam, is very simple—he makes the engine and boiler a fixture. These boats also possess other good qualities peculiarly their own. For instance, Mr. White claims for them a perfect unsinkableness, even when filled to the gunwale with water, and a double crew on board, an impossibility of capsizing them under any circumstances, as well as the constant readiness for active service, already referred to, in retaining their engines and boiler on board, even when slung up at a ship's davits. On a recent occasion, one of these cutters was tried over the measured mile in Stokes Bay, when she made a mean speed of 7 knots. This result is certainly exceptional when we consider that the boat is only 28ft. in length, and is driven by a little single cylinder engine of 3-horse power. It renders them eminently fitted for despatch boats. To test the qualities other than those of speed, which they are stated to possess, a subsequent trial was made with the steam cutter No. 3—the same vessel that gave the above good results under steam. The special object was to determine the practicability of hoisting up and lowering a boat loaded with engine and boiler, the latter filled with water, and a supply of coal on board for the furnace. The port poop davits of the "Duke of Wellington," screw three-decker, were appointed for the trial, so that as great a height as possible from a ship's davits was secured. With boiler filled, fire laid, bunker filled with coal, and the man attending the hooks and blocks of the falls on board, the total weight of the boat when suspended on the falls was about three tons. The falls were manned on the ship's poop by the ordinary number of men, and on the signal being given the cutter was run up to the davits and secured there under three minutes. The boat thus suspended was then carefully examined, but no sign of deflection was detected, thus clearly proving that she was quite capable of carrying her weights under these conditions with safety. The next step was to light the fire under the boiler, and soon afterwards the signal was given to lower the boat for service. In 2min. 3sec. from the time of the signal being given the boat was in the water and leaving the ship under a full head of steam. This result cannot be considered otherwise than as most satisfactory, and, in conjunction with the high speed these little craft attain, reflects great credit on Mr. White, their designer and constructor.

TRANSPARENT SOAP.

FANCY soaps form a large family, of which there are many varieties. One of these is transparent soap, the manufacture of which is extensively carried on in France and other continental countries. For the manufacture of this soap a large quantity of rectified spirits is required. Our own fancy soap manufacturers, however, are prevented from entering upon this branch of the trade owing to the restrictive measures imposed by the Board of Customs and the Inland Revenue department. As the duty on the rectified spirit is very high, and as this peculiar kind of soap cannot be made without it, no operations whatever can be undertaken, since it is impossible to compete with the continental maker, who has his spirits free of duty. To remedy the difficulty, it has been proposed to prepare the soap in a free manufactory until it is in the stage necessary for the introduction of the spirits, and then remove it into a bonded warehouse, where, under the supervision of the revenue officers, the spirits could be added, and the manufacture completed. Such an arrangement appears simple, and as it is merely that which prevails in the preparation of perfumed spirits and the manufacture of liquors, in the London and St. Katherine's Docks, we do not see why the authorities should not extend these provisions to soap. But it seems that the Boards in question are very hard things to deal with, as the trade has not yet succeeded in making any impression upon them, although they have been hammering at them for years. Notwithstanding that repeated applications have been sent in during the last six years to the Boards of Customs and Inland Revenue, the Board of Trade, the Lords of the Treasury, and the Chancellor of the Exchequer, nothing has been done. All admit the importance of the manufacture, but the ground on which the desired facility is refused is said to be that if they grant the privilege to one they must grant it to all; it is, therefore, better to manufacture this soap abroad. This is all very well in its way, and we will even assume these representations to be correct. But surely it is possible for the authorities to devise some means of meeting the point. There must be a woful lack of brains somewhere, which is really driving a valuable branch of business from this country. In the interest of our manufactures, we trust that some common sense will be shown in the matter, and that measures will be devised to enable our soap makers to carry on this special branch of trade.

ELECTRICITY AND TELEGRAPHY.

A NEW feature in telegraphy has just been introduced into France; it is now possible to exchange telegrams between any point in the European system of telegraphs and vessels at sea, by the aid of the semaphoric stations on the coast of France and Algiers. The commercial code of signals adopted by every nation is used for the exchange of signals between the station and the ship; telegrams addressed and sent by post to

Digitized by Google

the French semaphore stations with the requisite quantity of telegraph stamps will be signalled to a ship at sea instructed to call off the point in question.

The "Telegraphic Journal" of New York, established some time back in opposition to the "Telegrapher," has ceased to exist.

New lines are being erected in the Brazils, and in a short time we may expect to have Bahia, Pernambuco, and other important commercial places in telegraphic communication with Rio de Janeiro.

A convention has been signed by the Chilian Government with a telegraph company, who undertake to place all the Pacific republics in communication with Cuba, and, consequently, with the United States and Europe.

M. Miergues has modified the battery which we lately noticed. The whole was contained in a glass vase; he now does away with the vase, and substitutes for the zinc an amalgamated zinc cell, at the bottom of which is a disc of india-rubber.

In some experiments lately performed by M. Leroux, relative to the spontaneous re-establishment of the voltaic arc after an extinction of a short period, he found that for a certain time the current might be interrupted without destroying the arc; this time he estimates at 1-25th of a second. Writing on this subject, M. Wartmann remarks that he has observed this phenomenon since 1852, and has made use of it in some researches in the electric light; he finds that for 1-20th of a second the current can be interrupted.

The great difference between the sizes and gauge of various wires, as supplied by manufacturers for telegraph purposes, has been matter of note for some time past. The present wire gauge, generally called the Birmingham, is of an arbitrary nature, and appears to follow no particular rule, being given by different people in widely different diameters. Mr. Latimer Clark is now taking this question up, with the view to the appointment of a committee by the British Association, so that a gauge may be decided upon and generally adopted as the standard gauge. Mr. Clark suggests No. 16 wire, at the assumed diameter of 65-1000th of an inch, as a standard, and from that works the proposed size of the various wires, by constant increments of 25 per cent. in weight, and of constant decrements of 20 per cent. in weight. It is a peculiar fact that the curve-plotted from this gauge very nearly coincides with the Birmingham wire gauge of Mr. Holtzapffel, which is looked upon as the best authority. It is to be regretted that so much diversity should exist, interfering so materially in many ways; and we trust that this question will be thoroughly gone into, and the best and most uniform gauge adopted.

Mr. Rudall, of the London, Chatham, and Dover Railway, has lately introduced an improvement in the modified form of Daniell's battery (commonly known as the sulphate battery), generally in use in our railway system. The old form used to consist (this form is still much in use) of a trough divided by partitions, and subdivided by a porous plate let in. Several arrangements were tried and adopted for doing away with this partition, in order to occupy less space. Amongst these may be mentioned that known as the Silvertonn battery, consisting of loose porcelain double cells in the wooden trough, the copper being formed as a rectangular cell, in order to contain the necessary sulphate. The front of this cell was perforated all over with round equidistant holes, and at the back was attached a piece of leather closing over these holes, and acting as the porous diaphragm; in Rudall's modification the form of the copper cell is maintained, but the leather and the front face of copper are replaced by a porous plate which is let in and secured. The advantage of this battery is that the porous plate acts better, and the battery is cleaner; the absence of the copper face prevents the large amount of deposition that usually, in spite of the well varnished surface, took place. The present modification is found to answer well as a good practical battery for railway or other telegraphic work.

In order to render common equally serviceable with pure zinc, amalgamation with mercury is usually resorted to, as well as to decrease the local action. In Bunsen's batteries, where a stronger acid solution has to be used, great difficulty has always been experienced in keeping the zinc element well amalgamated, so as to reduce as much as possible the great expenditure of the metal. Several plans with this object have been tried, but generally have, for one or more objections, been put on one side. A very simple remedy has lately been tried by M. Demance, who simply places in the zinc cell several drops of mercury. The amalgamation is at once renewed. From the results of experiments made by him with cells whose zincs have been reamalgamated in this manner, he finds that the current obtained is of a remarkable constancy, and that the exterior disengagement of hydrogen is very feeble. In addition to this, after numerous experiments, he is satisfied that the intensity of the current is manifestly superior to that of a battery of the same number of elements under ordinary conditions. It is only under the influence of a current that this reamalgamation will take place. The mercury being in excess the zinc always remains bright, local secondary actions are removed, and when the zinc is withdrawn from the cell the absence is noted of the froth, generally due from impurities in the metal, which usually soils the surface.

DEATH OF SIR DAVID BREWSTER.

ANOTHER long and patient toiler in the paths of science has just gone to his last rest. Sir David Brewster, whose name has been prominently before the scientific world for many years past, died on the evening of Monday last, at the ripe age of eighty-seven. "Full of years and honours" are words easily spoken, but not so easily realized. Never were they more appropriately applied than to the deceased philosopher, whose whole life was a practical and beautiful comment upon unwearying progressive scientific research, discovery and application. He was originally destined for the Church, but choosing rather to follow the bent of his own inclinations he entered upon scientific studies and pursuits. His first active step in this direction was to accept the editorship of the "Edinburgh Encyclopædia," a work to which he made a number of important and interesting scientific contributions, and which he did not complete till 1830. He had already devoted himself principally to the science of optics, in which he was destined to attain so distinguished a reputation, and honours had poured thickly upon him. In the year 1807 he was made LL.D. of Aberdeen University; Oxford conferred on him the degree of D.C.L. and Cambridge that of A.M. Next year Dr. Brewster was elected a member of the Royal Society of Edinburgh, of which he subsequently filled the offices of secretary, vice-president, and president—holding the latter office at his death.

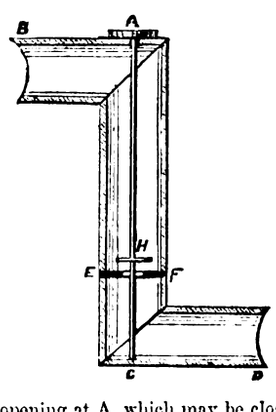
In 1815, Dr. Brewster received the Copley medal of the Royal Society for his discovery of the law of the polarization of light by reflection, and soon after was admitted a fellow of that body. In 1816 the Institute of France adjudged to him half of the prize of 3,000f., awarded for the most important discoveries made in Europe, in any branch of science, during the two preceding years. In 1819 Dr. Brewster received from the Royal Society the Rumford gold and silver medals, the Royal gold and silver medals, for his discoveries on the polarization of light, and from the Royal Society of Edinburgh the Keith prize twice, for his discovery of two new fluids in minerals and his analysis of solar light. It would be an almost endless task to enumerate all Sir David Brewster's discoveries and inventions, or to give a list of all the honours which were conferred upon him during a long life of unceasing activity. Without him our lighthouses would not have been what they now are, nor should we have had the perfect stereoscope we possess. The list of Sir David Brewster's contributions to scientific and general literature is a very long one, and includes our own pages, to which, some years since, he contributed a series of articles on his favourite subjects. In all parts of the world his merits have been fully recognised by learned bodies, whilst sovereigns have conferred upon him signal distinctions and decorations. To Sir David was due the establishment of the British Association, which grew out of a scientific meeting convened by him at York, in 1831. At the last meeting of this association it was remarked with regret that his health was not what it formerly was; in fact, he had to be removed from the hall on one occasion. Latterly his health had been failing, and at last nature gave way, and he sank to rest, leaving behind him a name which his survivors in science may envy and emulate.

PHOTOGRAPHY.

THE OXY-HYDROGEN LIGHT—OPERA-GLASS CAMERAS —DEVELOPING DRY PLATES.

OXYGEN is now largely used in the production of the lime light for photographic enlarging, and the manufacture of this gas may long be carried on with perfect safety but at last result in an explosion dangerous to life and limb. This arises from the use of an impure sample of black oxide of manganese, containing combustible matter, so that when chlorate of potash is added, and heat is applied to the retort, an explosion is the result. Safety from such accidents may be secured by heating the black oxide of manganese to dull redness in a crucible before using it in the manufacture of oxygen from chlorate of potash. In this roasting operation care must be taken that soot or carbon does not fall into the crucible, or that may result in an explosion. After preparing a quantity of oxygen, it is best to wash out the retort, and to throw the washings on a filter, which will collect the black oxide of manganese. This oxide is not changed by the process of making oxygen, and after having once been used for the purpose, of course it may be employed again with perfect security.

Last night (Thursday), Mr. John Traill Taylor, brought his method of securing safety from explosion during the use of the oxy-hydrogen light under the notice of the South London Photographic Society. He places a valve in each pipe leading to the two gas reservoirs, and these valves continue open whilst the light is being properly managed, but directly the operator, through any mistake, produces unequal pressure on the gas reservoirs, the gas is stopped on its way into the reservoir of its neighbour, closes the valve, and communication is cut off. Mr. Taylor described several valves which he had tried, that shown in accompanying cut being perhaps the most simple of the whole. B A C D is a bent piece of brass pipe



with an opening at A, which may be closed by the milled head therein represented. A C is a smooth wire down the centre of the pipe, with a light flat piece of ivory H free to move up and down there upon. E F represent the section of a flat brass ring in the pipe, and forming the opening to the valve. A piece of india-rubber tubing connects the end B with the right tap or taps of the lantern, whilst similar tubing, from the other end D, communicates with the gas reservoir. Hence, the gas-

Digitized by Google

when flowing in its proper direction from D to B lifts up the piece of ivory, as shown in the cut, and passes uninterruptedly, but if from any mistake the gas is pressed in the opposite direction, the valve closes, and the tube is sealed. Mr. Taylor says that this light valve has no tendency to cause a fluttering of the flame, which burns as steadily as ever, whilst the operator is secured from the danger of an explosion either by accident, carelessness, or design.

Mr. Taylor also says, "With respect to the cost, and quantity of oxygen obtained from chlorate of potash, if this salt be pure, and the operation conducted with extreme care, the quantity of oxygen which should be obtained from a pound of the chlorate, mixed with a quarter of a pound of oxide of manganese, is five cubic feet; but, from various circumstances, all that is really obtained is from 4ft. to 4½ft. As a bag containing this quantity will, with proper management, serve for supplying a lime light for an entertainment or exhibition of pictures, lasting a sufficient time to almost weary an audience of average appreciation, the cost of the 'raw material' for an evening's oxygen will be from one to two shillings, according to locality, for chlorate of potash varies very much in price, from 10d. per pound, when bought in large quantities, to more than double that sum."

Safety from explosions in the manufacture of oxygen may further be secured by having a metal retort made with a long vertical neck, and, instead of screwing on the "head-piece" in the usual manner, fix it to the top of the neck of the retort by means of 2in. of broad india-rubber tubing. Thus, the top of the retort will act as a safety valve, and be blown off when, as is sometimes the case, the gas is given off suddenly in large volumes.

The chief difficulty in the way of taking outdoor views consists in the cumbrous nature of the apparatus, even when dry plates are used. Hence, much attention has been drawn of late to the necessity for a little "opera glass" stereoscopic camera, to take pictures only about 2in. in diameter. The lenses must give sharp definition, so that the little pictures will bear enlarging when printed on collodion by the process of Mr. Johnson, as already described in these columns. The tourist will thus be troubled with the carriage of very little apparatus, and the "walking stick" legs desirable for such a camera will not be an inconvenience. Apparatus of this description is much wanted, and it is to be hoped that the demand will shortly be met by the introduction of good articles into the market. Small lenses giving a brilliant image upon a small plate being the best for instantaneous photography, it is desirable that all little cameras of the description just mentioned should be furnished with a rapidly acting shutter, which might be fixed either between the lenses of the double combination or immediately in front of the plate.

The tannin process with bromized collodion plates has been proposed for use with this little camera, and such plates are doubtless the best dry ones for the process. Unfortunately, there is some want of certainty with all dry plates, and it is disappointing, after getting home, to develope a bad negative of a scene which may never again be revisited. When the tourist is so situated that he is able conveniently to develope his plates within a few hours after he prepares them, the glycerine process is the simplest and most certain that could be adopted, and will give less trouble than any dry method.

There is considerable liability to produce fogging in the development of dry plates by the alkaline method, but as that practised and published by Mr. Russell Manners Gordon gives perfect security from such mishaps, it is desirable to reproduce it here. He uses three solutions—No. 1 consisting of pyrogallic acid 96 grains, absolute alcohol 1 ounce; No. 2, carbonate of ammonia 96 grains, water 1 ounce; No. 3, bromide of ammonium 8 grains, water 1 ounce. When the picture is to be developed, he first wets the plate with distilled water, and then mixes distilled water 1 ounce, solution No. 1 ten drops, solution No. 3 five drops, which mixture is poured over the plate, on which it is allowed to remain a few seconds only. It is then returned to the developing measure, where five drops of solution No. 2 are added. This mixture, on being again applied to the film, at once brings out the picture, and after a little time, if from under-exposure the image does not develope quickly enough, four or five drops more of solution No. 2 may be added. The plate has then to be washed, and flushed with a little acid pyrogallic solution, to neutralise any remaining traces of alkali, after which the intensifying operations are performed in the usual manner.

NOTES ON RECENT SCIENTIFIC DISCOVERIES AND THEIR PRACTICAL APPLICATIONS.

A NEW VOLTAIC BATTERY—CONVERSION OF CARBONIC INTO OXALIC ACID—AN IMPROVED PROCESS FOR SILVERING GLASS.

A NEW voltaic combination of great power was exhibited to some of the learned societies last week. It is the invention of Messrs. De La Rue and Hugo Müller, and has been designed for Mr. Gassiott. The elements consist of small cylinders of pure zinc and chloride of silver. The latter is cast upon a thin silver wire which forms the conductor. The exciting liquid is merely a dilute solution of common salt. In the battery shown the cylinders were only 3in. long, and about the size of goose-quills, arranged in two ounce phials cut down to two-thirds of their length, but a series of ten such couples decomposed water with great rapidity. By the chemical action taking place in the cell the chloride of silver is reduced and chloride of zinc formed. The action proceeds so long as any chloride remains, for the reduced silver adheres to the wire as a spongy mass, which allows the liquid to permeate to any unreduced chloride. The first cost of such a battery will be considerable, but as the only loss will be a little zinc, it will be very economical in working. Mr. Gassiott, it was said, is having a battery of 1,000 pairs constructed, of which, no doubt, the scientific world will in good time hear and see much.

Many chemists have tried to effect the direct conversion of carbonic into oxalic acid, and it was announced at the last meeting of the Chemical Society that one had succeeded in the attempt. A communication from Professor Kolbe stated that a German chemist, whose name we did not catch, had accomplished the object, by passing a stream of moist carbonic acid over metallic sodium distributed through sand, and heated to the boiling point of mercury. After some time, oxalate of soda was found among the sand. It had been noticed before that potassium amalgam absorbed carbonic acid and formed oxalic acid.

The celebrated chemist Liebig offers the fine example of a man who can, at times, descend from the loftiest flights of philosophical speculation to administer either to the wants of mankind by the preparation of an extract of meat, or to their vanities, by showing how mirrors may be easily and cheaply made. His last directions for the silvering of glass we borrow from the "Annalen der Chemie und Physik" and the "Philosophical Magazine." There is nothing new in the process, except the introduction of a small amount of copper, which has, however, important advantages. Without the copper the deposit of silver is apt to show speckles and pinholes, which are completely avoided in the process now described. The directions for preparing the various solutions are rather complicated, but we will endeavour to give them in a short space. First of all, a solution must be made of one part of fused nitrate of silver in ten parts of distilled water. Then a solution of 242 grammes (say half a pound) of sulphate of ammonia in water, made up to 1,200 cubic centimetres (two pints two ounces). Then a solution of caustic soda, free from chloride of sodium, of about the specific gravity 1·05. A silvering solution, designated A, is then composed as follows:—

Take 100 volumes of the ammonia solution
140 „ nitrate of silver solution.
750 „ soda solution.

The sulphate of ammonia solution must be poured gradually on the silver solution, and the soda also added by degrees. This mixture must stand three days to deposit, and then the clear liquor can either be decanted or drawn off with a siphon.

A reducing liquid (*a*) is now to be prepared by dissolving 50 grammes of white sugar candy in sufficient water to make a thin syrup, to which is added 3·1 grammes of tartaric acid. This mixture must be boiled for an hour, and then diluted to 500 cubic centimetres (0·88 pint). A solution (*b*) is made by dissolving 2·857 grammes of tartrate of copper in 500 cubic centimetres (0·88 pint) of water.

The reducing mixture B is made by mixing one volume of the sugar solution (*a*) with one volume of the copper solution (*b*), and eight volumes of water.

We now come to the actual silvering mixture. This is composed of:—

50 volumes of solution A
10 „ „ B
250 to 300 „ „ distilled water.

Solution A must be mixed with the water in a separate vessel; the solution B may be added in the bath. The reduction and deposit of the silver takes place best at a temperature from 70deg. to 85deg. Fah. The quantity of silver deposited Liebig states will be about a quarter of an ounce avoirdupois on the square metre, that is 1·2 square yard. Thus the manufacture of mirrors by this process will be very economical.

THE ANEMOMETER AND THE RECENT GALES.

THE recent storm at Liverpool was of probably unprecedented severity; it has certainly not been equalled during the present generation. The anemometer, or wind register, at the Bidston observatory, was erected in June, 1851, with a scale extending to 45lbs. on the square foot, which was then deemed to be ample for any contingency. This, says the "Liverpool Albion," answered very well until December, 1863, when, during a storm of great severity, the registering pencil was sent by three gusts to the extreme limit of the scale, 45lbs. to the square foot. Accordingly, when the new observatory was erected, the anemometer sheet was made to register 60lbs. to the square foot, and it was not deemed possible that any gale could visit these latitudes whose strength would exceed that limit. Thirty-six pounds to the square foot is set down in the charts as a "violent hurricane," so that those who framed the scale were quite justified in that opinion. Indeed, 60lbs. seemed to be an unnecessarily extended limit. The wind first began to increase perceptibly in strength about 9 a.m. on the 30th, but it did not assume a serious form until the evening of the 31st, when it rapidly increased in violence until, at half-past eleven at night, the anemometer registered one gust at a pressure of 51lbs. to the foot. At this time the wind was blowing from the west north-west, accompanied by rain, which continued through the greater part of the night. About 8 a.m. on Saturday the wind moderated, and the weather cleared, but soon afterwards the wind, veering slightly to the north-west, again increased in force, until between eleven and two o'clock the registering pencil was continuously sent far beyond the limit of 60lbs.; and Mr. Hartnup calculates, from the force with which the pencil was driven, that the pressure at several periods could not have been less than from 70 to 80lb. to the square foot. This is a tremendous pressure, so far in excess of anything hitherto recorded that it is questionable whether any part of the earth, even the West Indies, is often visited by a wind-force of greater severity. At about 3 p.m. the wind gradually subsided, and by sunset blew only a moderate gale. The barometer registered at midnight on the 29th 30deg. 31min. and from that time it continued to fall steadily until noon on Saturday, when it stood at 29deg. From this time it again rose, and at 2.30 p.m. stood at 29deg. 13min. During the great and disastrous hurricane of January 7th, 1839, the most severe on record, the barometer went down to 28deg., but unfortunately, so far as we have been able to learn, there is no record of the strength of the wind. It is not probable, however, that it even reached the excessive pressure of Saturday. Considering the tremendous force of the storm, it is remarkable that the disasters in the town and district were few, and of a slight character.

CRYSTAL PALACE.

WE recently noticed the partial restoration of the tropical end of the Crystal Palace, and it is with pleasure that we are now able to announce that the newly built end having been completed, will be thrown open to the public to-morrow (Saturday). The erection has been undertaken by the Hamilton Windsor Iron Works Company (Liverpool), under the direction of Mr. Edwin Clark. The finishing of this portion of the Palace has afforded the opportunity of locating the show of British and foreign birds there. Moderately heated, the tropical department of the Palace forms an unequalled place for such an exhibition. There will be an unusually large show, including specimens of all our native favourites, every variety of canaries, parrots, and parrakeets of every description and plumage, cockatoos, hybrids, albinos, &c., &c. As a novelty, the Monti fountain basin will be stocked with a large number of exceedingly rare water fowls. There will also be an interesting collection of pigeons of every sort. The birds will be judged this afternoon, and the show will be open at ten o'clock to-morrow morning, a concert being given as usual at three o'clock. The exhibition will be continued next week from Monday to Friday.

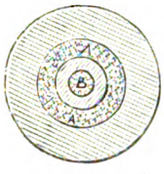

FIG. 6

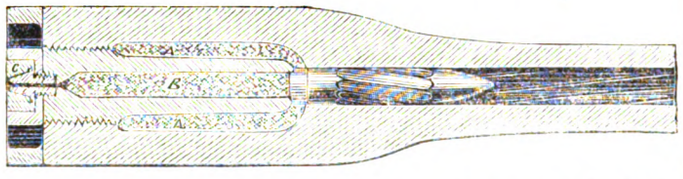


THE ACCELERATOR GUN.

SOME months since we briefly referred to a gun on the accelerator principle, which has been brought out in America, and which had successfully stood some searching practical trials. This gun is the invention of Mr. A. S. Lyman, of New York, who has recently patented it in England. In this gun, in addition to the charge of powder supplied in the ordinary manner there are additional charge chambers, the charges of which act upon the projectile in succession after the initial charge has been exploded, whereby the motion of the projectile is accelerated. Mr. Lyman has designed two of these guns, the first arrangement being represented in figs. 1 to 5 of the annexed engravings. Fig. 1 is a top view, and fig. 2 a vertical longitudinal section of the gun. Fig. 3 is a cross section through one of the accelerators or additional charge chambers. Fig. 4 is a rear view, and fig. 5 a front view. The arrangement consists in forming in the body of the gun below and in a line with the bore several, say four, accelerating chambers A B C D, which are charged through openings leading from the upper part of the gun; these openings, after the charges have been inserted, are closed by screw valves E. The valve stem projects up through the screw and has a cap nut F on its end to keep out water. It is arranged so that when the screw has made half a turn in being withdrawn, it strikes the cap F and lifts the valve from its seat without revolving it, whereby friction is avoided; a copper cup G prevents windage.

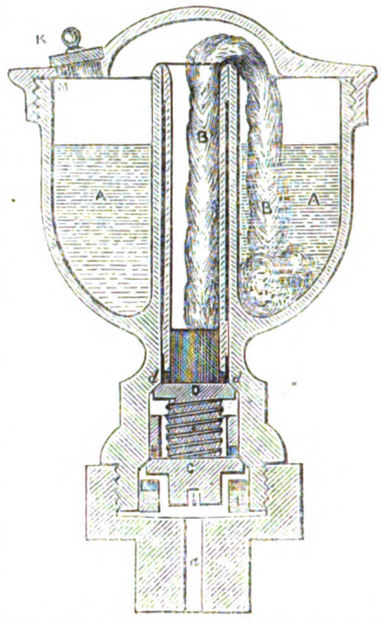
When the gun is fired the projectile is driven by the initial charge at H, which is comparatively small, past the first accelerator A, and the resistance of the shot causes the fire to set back down into and ignite the powder in this accelerator. This raises the pressure perhaps half as high as it was raised by the small initial charge H before the inertia of the projectile was overcome. The action of each of the other accelerators B C D is the same. The quantity of powder considered necessary for these accelerator guns for a projectile of (say) 280lb., is as follows:—For the initial charge, 3½lb. of mammoth powder; for the first accelerator A, 20lb. of mammoth powder; for the second accelerator B, 20lb. of No. 7 powder; for the third accelerator C, 25lb. of cannon powder; and for the fourth accelerator D, 25lb. of quick and strong powder. The accelerator plugs I should be of soft cast steel fitting closely in and protecting the cast iron from the fire of the powder.

In constructing the breech of guns, when provided with accelerating chambers according to this arrangement, Mr. Lyman has a cap K screwing on the outside of the breech, as in the Whitworth gun, but in front of this cap is a taper plug L, with its stem projecting back through the cap, and with a nut M on its rear end so as to have about half an inch play in order that when the breech is opened the cap K will make half a turn before it strikes this nut M, and lift the plug L from its seat without necessarily revolving it at the same time; friction and the power required to open the breech are thus greatly lessened. N is the sabot, which is made of a case of copper or sheet brass, filled with sheets of pasteboard. Where the back end of the projectile is tapered an iron plate O is placed in the front of the sabot to prevent the pasteboard being driven forward around the projectile. The second arrangement is represented in longitudinal section in fig. 6 and in cross section in fig. 7. It consists in constructing an additional charge chamber A at the breech and outside the bore of the gun. When the initial charge at B is fired, a wad C in front of this charge, which closes the communication between the two charge chambers A and B, is forced forward, starts the shot, and allows the fire to set back and ignite the accelerating charge A. This arrangement applies to muzzle-loaders, and the loading must be effected while the gun is in a vertical position, or nearly so; while loading, the powder, after filling the ordinary charge chamber B, runs over into the accelerating chamber A. The amount of powder in the chamber A should be about seven times that in the chamber B. We are expecting a report of the trials of this gun from America, which we shall publish as soon as we receive it.

SCHLŒSSER'S LUBRICATOR.

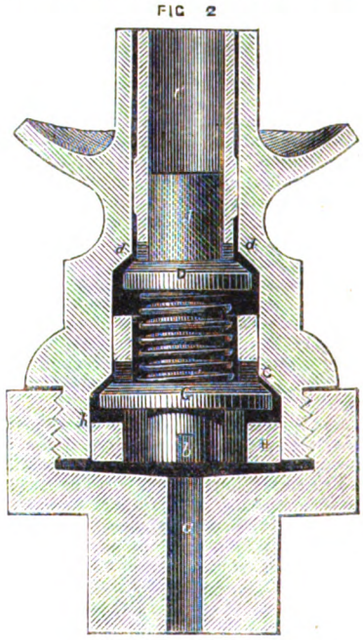
IT is well known that steam alone, and the water practically resulting from its condensation, very efficiently lubricate ordinary cylinder pistons and slide valves—especially when those parts are not very heavy, as with locomotive work, for instance. The construction of Shlœsser's self-acting lubricator is based upon the principle of furnishing no grease at all to the cylinder and valve chest as long as the engine is working under steam, but of instantly lubricating the parts as soon as the piston and valve are working dry, through their own momentum or otherwise. This lubricator, a German invention, has already been introduced on a large number of the lines in that country. It was shown in the patent locomotive of Herr Krauss at the Paris Exhibition, and in the Prussian machinery section. We believe it is being introduced into England by the London agents for the Bochum Steel Company, Messrs. Heintzmann and Rochussen. The external appearance of this lubricator is that of an ordinary cylinder oil cup, having a small opening X in its corner for the introduction of oil. Should tallow be used the cover must necessarily be taken off. The lubricant is conveyed from the annular chamber containing it into the central tube C by means of a wick. In order to prevent the chance passage of any grit, the bottom

FIG 1



of this tube is fitted with a thimble of wire gauze. Below this tube are two valves D and G, opening from above. Fig. 1 shows the position of these valves when the cylinder is under steam; fig. 2 is an enlarged view of the valve when open. Valve D is kept closed up against its slot by means of a spiral spring when the engine is standing still, so that no oil can escape; and when the engine is working under steam this action is evidently reinforced by means of the pressure of the steam on its bottom. But as soon as steam is shut off, and the engine

FIG 2



works empty, the strong exhaust in the empty cylinder or valve chest overcomes the spiral spring. The valve then descends and affords an annular opening, through which the oil escapes out of the cup. This takes place as long as the partial vacuum in the parts makes itself felt, but as soon as the engine stops, or steam is let on, the valve again closes. The amount of lubrication can be regulated in different ways, either by increasing or diminishing the threads of the wick, by varying the stroke of the valve by screwing up or down the nut on its threaded spindle *e*, or by varying the number of the openings *d*, *d*. The function of the second valve G, below the first D, is comparatively unim-

Digitized by Google

portant. It is for preventing the inlet of the water of condensation into the working parts of the apparatus. This valve rests on a ring H, made with grooves H H, for the escape of the grease, and having at its foot another groove intended for the same purpose. The descent of this valve can also be regulated by adjusting the ring H. A saving of as much as two-thirds of the usual quantity of grease is claimed for this lubricator as the result of the trials on the Nassau line of railway.

INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of the Institution of Civil Engineers, held February 4, 1868, C. H. Gregory, Esq., President, in the chair. The paper read was on Floods in the Nerbudda Valley: with remarks on Monsoon Floods in India generally, by Mr. A. C. Howden, Assoc. Inst. C.E.

This valley was described as being bounded on the north by the Vindhya and on the south by the Sautpoora ranges of mountains, and as consisting principally of black cotton soil, which was renowned for its fertility. The drainage of the valley supplied nearly the whole volume of the waters of the Nerbudda river, which traversed it in a direction nearly due east and west. The river took its rise in the Vindhya Mountains, at an elevation of 3,500ft. above the sea; its fall to Jubbulpore, 190 miles distant, was 10ft. per mile, and thence to the Gulf of Cambay, the fall might be estimated at about 2ft. per mile, the total length of the river being 800 miles. The width at its source was only 1 yard, while a little above its confluence with the Towah, 360 miles down stream, it was 900 yards, and at its mouth upwards of 1 mile. In an ordinary monsoon the level of the water rose between 30ft. and 40ft., but it had been known to rise nearly 60ft., when it overflowed the banks. Midway between the river and the Sautpoora Mountains, this valley for a length of about 270 miles was traversed by the north-eastern extension of the Great Indian Peninsula Railway, which crossed all the tributaries falling into the river on its southern bank; and it was the floods to which these feeders were liable that formed the subject of the present paper.

The floods of this region were divisible into two classes, according as they affected the plains, or the rivers. With regard to the former, it was remarked that the greater part of the Nerbudda Valley traversed by the railway was almost a level plain; and that although the average rainfall in the district, 46in., or 11½in. for each of the four monsoon months from June to September, could easily be provided for by the natural watercourses, yet that as much as 10.50in. fell in eighteen hours, in August, 1864, causing sudden and disastrous floods. It was observed that, in constructing a railway across plains of this description, great attention should be paid to the rainfall of the district, and ample provision should be made for carrying off the maximum amount speedily, without allowing it to dam up; as few embankments (especially those formed of black soil) could withstand the immense pressure then brought upon them, although the period of danger might not exceed twelve hours during the year, and should an opening once be formed, the scour was such that the embankment speedily melted away.

The principal rivers crossed by the railway in the Nerbudda Valley from Bhere to Bagra, a distance of 100 miles, were the Towah, Gungal, Matchock, Karlee Matchock, and the Suktha or Chota Towah, besides the Sconce Jamnee, Hurda, and other nullahs. The greatest flood known for ten or fourteen years, or according to native report, for thirty years, occurred in 1864, when, on the 15th of August, the river Towah rose 47ft. in a few hours; and it was estimated that the velocity at the surface was 16.58ft. per second, the fall 4.25ft. per mile, and the discharge 976,629 cubic feet per minute. It had been asserted that the flood of 1864 was an unusual one, but that of 1865 was of a similar character; while the flood of 1866 exceeded its predecessors, both in force and magnitude. The next important river was the Gungal, the highest known flood in which took place on the 22nd of July, 1864, when with a fall of 3ft. per mile, the mean velocity from calculation being 166.14in. per second, the discharge amounted to 732,123 cubic feet per minute. Two subsequent floods occurred in this river on the 8th and the 29th of August, 1866, and then, the fall being as before 3ft. per mile, the mean velocities were found to be from observation 153.68 and 110.22in. per second respectively, the relative discharges being 477,820 and 109,494 cubic feet per second. Some idea of the force of the current in Indian rivers on such occasions may be gathered from the fact, that in a comparatively small river, 30ft. plate-girders had been carried 7 miles down stream; while, in 1866, masses of masonry weighing 1,600 tons and 1,000 tons had been washed away from two of the piers of the Towah Viaduct, without a single stone being recovered.

In conclusion, the author expressed the opinion that, in bridging rivers of the description referred to, in the first place, wide spans were indispensable; for the current was so swift, and the rise of water so rapid, after a heavy fall of rain, that any contraction of the waterway caused a dangerous scour and backing up. Secondly, he thought that next in importance to having as few piers as possible, was the necessity of giving them the greatest strength, by building them of solid block in course, set in cement. Thirdly, that the face of the cutwater of piers should always be tool-dressed to reduce the friction, the "bush" frequently left on forming an obstruction. And, fourthly, that when rubble backing was used, care should be taken in suspending work, to finish off below high-water level with a bed of solid block in course, as otherwise the water would penetrate the work, and speedily blow up the pier.

SOUTH OF ENGLAND LITERARY AND PHILOSOPHICAL SOCIETY.

THE annual soirée of the above Society was held on Friday evening last, February 7, at the Hartley Institution, Southampton, by permission of the Hartley council. The Society has been in existence for several years, and was formed to meet the generally-expressed want of an association which should serve to bring together occasionally and to promote the co-operation of those in the town of Southampton and the surrounding neighbourhood who are occupied in the pursuit or interested in the progress of literature and science. The Society was formerly presided over by the late Lord Palmerston, and has now for its president the Hon. W. Cowper, M.P., and the soirée just held was rendered more attractive by the presence, for the first time, of the right hon. gentleman, who on this occasion delivered an interesting address. The Hartley Institution is a place eminently suited for conversazioni and soirées, the number of large rooms it possesses enabling the exhibition and classification of the various objects easy to accomplish and most convenient for show. In the reading-room were shown a collection of microscopes, spectroscopes, zoetropes, and other optical instruments; models of Jerusalem and the Pyramids, exhibited by Colonel Sir H. James; new invention for saving life in case of fire, by Messrs. Strugnell and Shepperd; a very good collection of antiquities and other objects of interest, by Mr. S. Sharp, of Northampton, &c. In the library were exhibited a large collection of objects of ethnological interest, by Mr. E. T. Stevens, of Salisbury, &c; and in the upper rooms the following objects of interest were exhibited:—Smoke rings and spectroscope, by Dr. Bond; gigantic soap bubbles, various forms of instruments for registering variations of temperature; and the spygmograph, an instrument for indicating on paper the beats of the pulse and the motions of the heart, confirming what is learnt by palpitation, Dr. Langstaff; and a collection of electrical and philosophical instruments, by Mr. W. H. Preece.

It was in these upper rooms that the principal objects of interest appeared to be located, to judge by the constant state of crowding; in one room was to be seen a large collection of telegraphic apparatus for ordinary speaking and for railway signalling, and other purposes. In the next room Mr. Preece's large ebonite plate electrical machine appeared to be the principal source of amusement and instruction; the apparatus connected with this machine for exemplifying experiments in frictional electricity were remarkable alike for the excellence of their workmanship and for their number: in fact, a collection that privately has rarely been equalled. Amongst other objects of particular interest, to which attention was constantly called by the loud reports of the fuzes, was Siemens' dynamo-electric apparatus for blasting purposes; the facility with which fuzes could be exploded at apparently any distance, by the simple exertion of muscular force in turning a handle, was truly astonishing. In the same room was also Ansell's firedamp indicator; a description of this has appeared so often that we cannot mention more here than that it formed, on account of its novelty in Southampton, an object of great interest. These two last apparatus were, by kind permission of the inventors, exhibited by Mr. G. E. Preece. The large theatre was frequently visited to hear an excellent selection of vocal and instrumental music; and shortly before ten o'clock the balcony and the body of the hall were well filled to listen to an address from the president of the Institution, who was introduced by the Mayor in an appropriate speech.

The Right Hon. W. Cowper said, as president, he was very glad upon this the first opportunity he had had of attending their annual conversazione, to congratulate the members of the Society upon the prosperity of the undertaking. One of the characteristics of the present day was the great achievements which were made by combinations or associations; and they found even in philosophical and literary pursuits they required a combination, a concourse of persons of similar tastes, who, by being united, were enabled to make progress which otherwise they would not be able to succeed in doing. The addition of social intercourse to the pursuit of science seemed to him a discovery quite worthy of note. This Society was not a society only for recreation, but they desired, he was sure, to promote utility as far as they could, and to look beyond their own sphere and see what useful things the Society could accomplish. During the short time that he was permitted to address them, he rather wished to improve the occasion by considering what was possible to be done in this great city by the means which were always existing in it to assist in the solution of some of those great questions respecting the education of the working classes, and which now deserved and received so much public attention. Since the great question of the Reform Bill had been settled, he considered the question which most urgently pressed for solution was the question of improvement in the education of the people; and the employment of scientific education in all places of tuition was a question which had now to be dealt with. But perhaps the special requirement to which their attention should be most directed was the mode by which technical education could be given to the artizans of this country. By technical education they understood the teaching of those elementary principles of science which were involved in the ordinary process of skilled labour—the application of science to the work which was carried on in the various manufactories. It was not necessary that he should speak of the modes in which science should be taught in upper schools, but he might mention that a very interesting experiment was about to be tried in the establishment of a college for young ladies, which was to be formed upon the principles of the Oxford and Cambridge Universities. But with regard to the technical education which was about to be given to the artizans of the country, they found that the importance of it was not fully recognized, and that the means were still very deficient. He thought there could be no doubt at all that a scientific training was just the sort of training which would be advantageous to working men. When we looked abroad and saw what the rest of the world was doing in this direction, we should soon find that if we stood still we should be left far in the rear. Now the governments of the most enlightened countries of Europe had been devoting great attention, and granting considerable sums of money, for the diffusion of technical education among the working classes. In France there were 25,000 evening classes, with about 600,000 pupils, and in those classes facilities were afforded for bringing to the artizan that scientific training which he needed. The English artizans, as shown from the Paris Exhibition, no longer held the same relative position in regard to Prussia, Switzerland, Austria, and France, that they did on former occasions. Now, how did we stand in England? Certainly the Committee of Privy Council on Education had exerted itself to extend the teaching of science, and we had at the present moment about 200 science schools, with some 10,000 pupils who passed examnations, but really those schools were not what they were called—they were merely elementary schools, with a little smattering of science in them. It seemed to him that Southampton was just the place where they ought to see a science school flourishing and successful. Those large engineering establishments which existed in the town must provide a number of youths, to whom it would be of incalculable importance to acquire such a knowledge as would assist them in their trade. They had in that scientific department of the Government, presided over by the officer who was so distinguished in the scientific

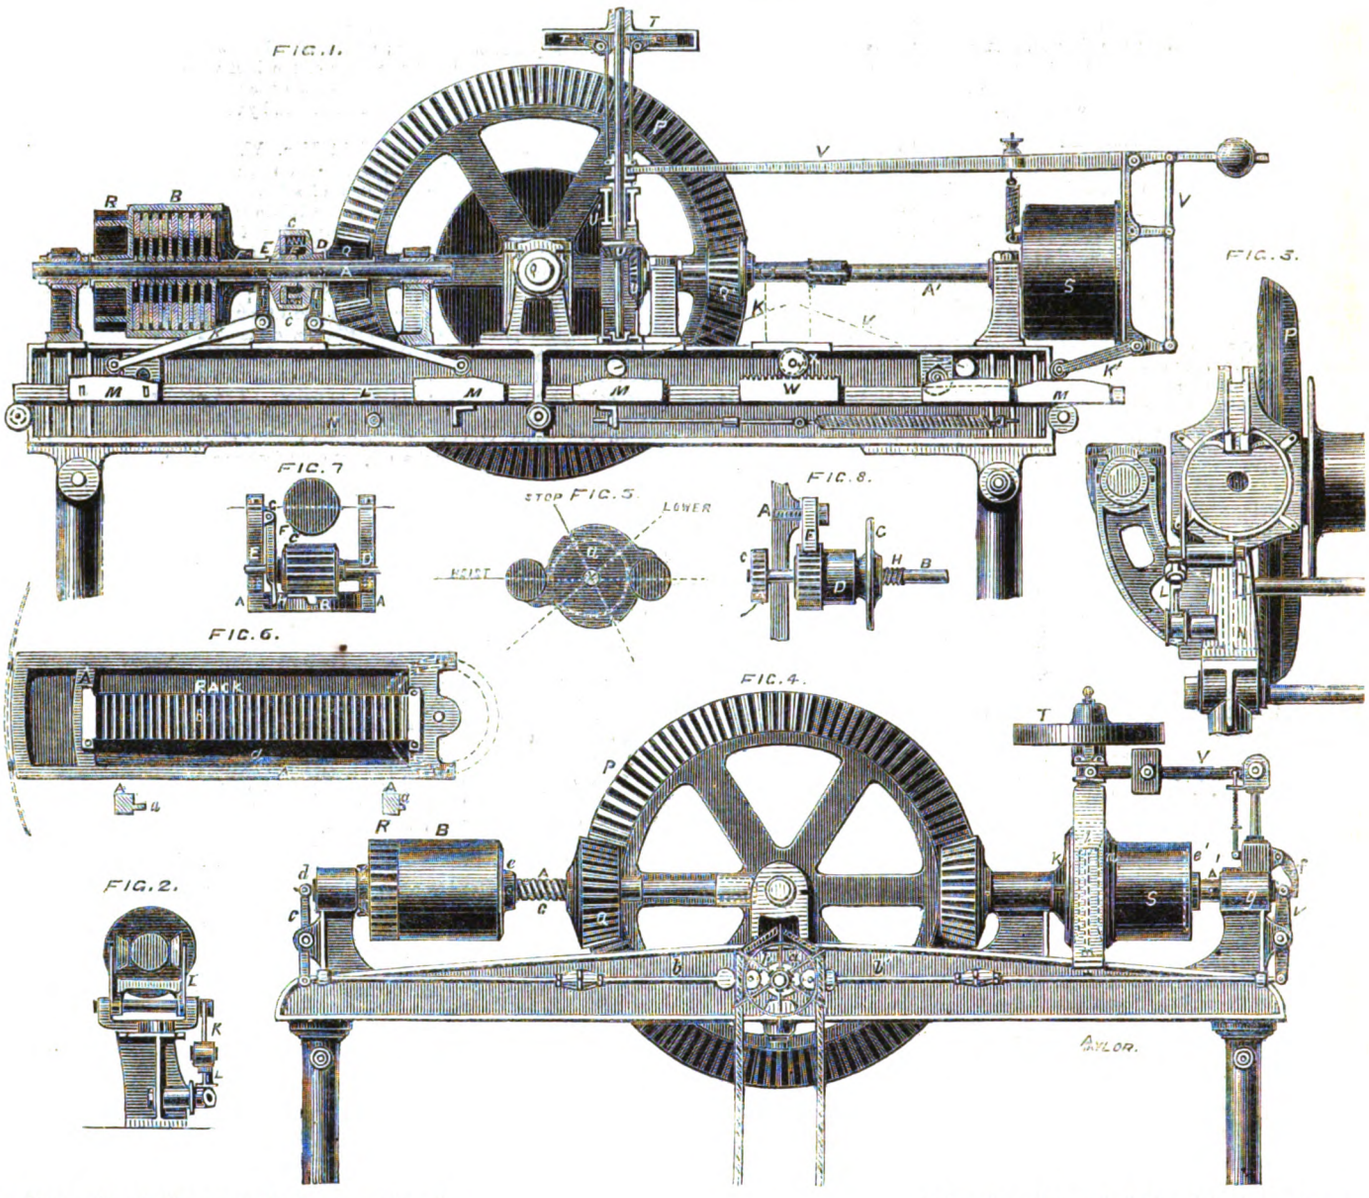
FRICTION COUPLING BRAKE.

BY MR. T. A. WESTON.



world as well as in his own profession, a number of persons to whom a scientific education would be most useful. They had in the Hartley Institution class rooms, a laboratory, a library, and a museum —much that was wanted; and the able, zealous, and enthusiastic principal, Dr. Bond, with his coadjutors, had already established engineering classes, in which such technical education as he had referred to might be given. The Hartley Council had shown their readiness to do what was possible in this direction by being, he believed, the first public body in the country who had taken advantage of what had been done by the Committee of Council on Education with regard to artizans' science exhibitions. There was, he was sure, in the town a number of gentlemen who would be happy to co-operate and do what was necessary in establishing a really efficient science school in connection with the Hartley Institution. He should be glad to see some committee formed, some association of persons who were interested in the matter, and then he had no fear of any lack of pupils. He hoped, therefore, that Southampton, so distinguished for its commercial activity and enterprize, and in many other respects, might also have linked to its reputation a science school added to the few already in existence in other parts of the country.

A vote of thanks was accorded to the right hon. gentleman on the motion of Colonel Sir H. James, seconded by Dr. Langstaff. A similar compliment was also paid to the Mayor for presiding, on the proposition of Dr. Bond, seconded by the Right Hon. W. Cowper. the latter complimenting the town upon having so excellent a chief magistrate.

FRICTION COUPLING BRAKE.

THE friction coupling brake invented by Mr. T. A. Weston, of Birmingham, is so well known to our readers, that it is not necessary for us to do more than refer to it in introducing Mr. Weston's most recent applications of that useful invention. In the present instance the invention is applied to hoisting machinery, gun carriages, &c., and consists of arrangements for applying and withdrawing the pressure requisite for operating the coupling brake. Fig. 1 in our engraving represents a front elevation of a power hoist with Mr. Weston's improvements applied; figs. 2 and 3 are end elevations of the same. Upon the shaft A, fig. 1, carrying the coupling brake B is placed a short hollow cylinder C, having a central boss D capable of turning freely on the shaft A. The lid or cover E of this cylinder is also provided with a central boss F so as to turn freely upon the shaft A with the cylinder C, and it is forced outwards from the cylinder by springs G contained therein. The central boss of the lid or cover is extended along the shaft and made to press by the intervention of the keys F^1 upon the discs H of the coupling brake B when required to effect the coupling action of the discs. When the springs exert their force upon the coupling brake the spring box C may revolve with the shaft, but when the coupling pressure is withdrawn by the spring box and its cover being mutually compressed together the spring box is brought to rest with and by the parts employed to compress it.

Upon each side of the spring box is a forked bell-crank lever I by which the spring box C may be compressed or released as the arms K of the bell-crank levers are elevated or depressed by the longitudinal motion of a sliding bar L, which is provided with inclines M for that purpose. N is a casting or girder carrying one end of the barrel shaft O of the hoist, the other end of the shaft being also supported. On the shaft O a bevel wheel P is placed next the girder N; upon each side of the bevel wheel P, and gearing therewith is a bevel pinion Q Q^1 with shafts A A^1 lying parallel to the girder N, bearings being formed for the same. To each coupling brake B are attached pinions R, which gear into corresponding spur wheels fixed upon one common driving shaft for the purpose of effecting the hoisting and lowering motions accordingly as one or other of the pinions is coupled with its shaft A or A^1. The pinion shaft A^1 is extended towards one end of the girder into a stationary brake box S fixed to the girder N, and to which is applied the speed governor T. The governor weights T^1 revolve horizontally, deriving their motion from light bevel wheels U upon the shafts A^1 U^1. The governor weights act by the levers V upon the stationary brake box S, and arrest any excess of speed in the act of lowering. The governor brake S is also acted upon by a lever K^1 to arrest the lowering motion at any point. The sliding bar L extends the whole length of the girder, and is in contact with the arms K of all the bell-crank levers of the coupling brakes as well as the lever K^1 of the governor brake, and lifts or drops them by suitably arranged projections on inclines M on the said bar. The projection M upon the sliding bar may be adjustable so that the hoisting, lowering, and the stop motions may follow each other in a convenient manner. The stop motion is obtained by pressure upon the stationary brake box effected by the incline M^1 and lever K^1. The sliding motion of the bar I may be effected by a toothed rack W attached thereto and gearing with the pinion X carried on the spindle Y of a sprocket wheel. The hoist is operated by the parts described, to which motion is conveniently imparted for the purpose by means of an endless rope and sprocket wheel attached to and carried by the pinion shaft X.

HOT BLAST STOVE AT THE THORNABY WORKS.

BY MR. WHITWELL.

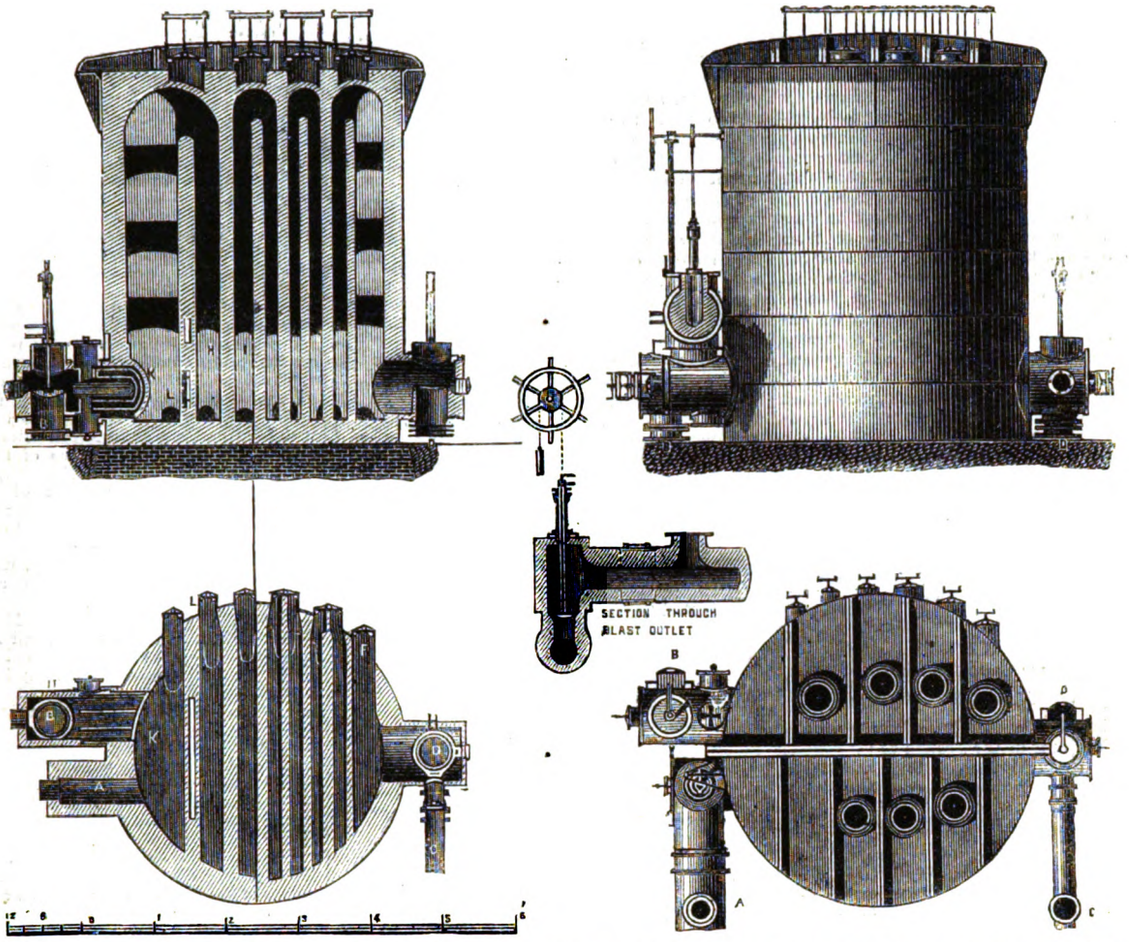

Fig. 4 represents a side view of another arrangement of hoist Mr. Weston has also brought out. A is a hollow shaft carrying a coupling B and a pinion Q gearing into the bevel wheel P to transmit a hoisting motion to the hoisting barrel by the action of the spring G upon the coupling B, the wheel R of which is geared to a wheel upon the driving shaft, as described with reference to fig. 1. This coupling pressure is removed in lowering by the cam *a* (shown in detail, fig. 5), acting upon the rod *b* and levers *c* through the pushing rod *d* within the hollow shaft A, the rod *d* forcing backwards the disc *e* of the coupling and relieving the latter from the pressure of the spring when the shaft A may turn in the contrary direction in which it is carried by the descending load. The lowering motion is suitably retarded by the governor T exerting its force upon the brake S through the intervention of the levers V, crank *f*, and pushing rod *g* which forces inwards the disc *e* upon the discs of the brake S. Upon the shaft A^1 is fixed a bevel wheel *k*, which by the pinion *l* transmits motion to the governor T and to the brake drum S by the pinion *l* also gearing with the wheel cast on the drum S; by this means the drum S and the discs connected thereto are rotated in a reverse direction to the other series of discs carried upon the shaft A^1, which contrary motion in the discs adds to their brake action. To stop the hoist wholly the cam *a* has a projection to act upon the rod *b*, lever U, and pushing rod *g*; the hoist is thus conveniently operated by the sprocket wheel *h* and rope *i* carried by the shaft Y, upon which is fixed the cam *a*.

Fig. 6 is a plan of the slide of a gun carriage to which Mr. Weston's invention is applied; fig. 7 is a transverse section of the same, together with that of the gun carriage thereon. A is the framework of the slide, one side of which has an inclined rib or rail *a*. B is a rack secured to the frame A, into which rack the compressor or disc brake C gears by spur teeth formed on its outside. D is a shaft carrying the brake C, and is supported in the sides E of the gun carriage; this shaft may be locked to or released from the sides of the carriage by any suitable means. F is a forked lever, the forks embracing the shaft D and vibrating between lugs G upon the carriage side; the tail H of this lever bears upon and traverses the inclined edge of the rib or rail *a*. As the carriage is driven by the recoil of the gun backward along the slide the lever E is gradually carried inwards against the brake or compressor C as the tail H traverses the inclined rib or rail *a*; during this backward motion of the carriage the shaft D is locked to the carriage sides E; the brake discs thereon are therefore stationary, whilst the discs attached to the drum C receive motion from the rack B. As the pressure is thus gradually increased upon the brake C an increasing resistance is thereby afforded to the recoil of the gun carriage.

Fig. 8 represents this invention as applied for controlling the lowering motion of an ordinary crane. A is the framing of the crane supporting the shaft B; C is a pinion keyed thereon and gearing into the spur wheel of the winding barrel; D is the brake box having a ratchet wheel E formed thereon on which the pall F acts. G is a hand wheel screwed to fit the screw H formed on the shaft B for the purpose of coupling the discs of the brake D; the pinion C turns in the direction shown by the arrow when lowering. Lowering is effected by unscrewing the hand wheel upon the screw thread H of the shaft B, which is again restored to its original position and again coupled with the brake box D by the lowering motion of the shaft.

We should add that this invention has had numerous practical applications, all of which are giving every satisfaction. For instance, the brake has been applied to numerous windlasses in the Royal Navy, the authorities having highly approved of it, and ordered its adoption. Then, again, there are eighteen hoists on this principle which are at work at the London Road Station, Manchester, of the Manchester, Sheffield, and Lincolnshire Railway. These are 90f.t lifts, and are for general warehouse purposes. With regard to the application of the principle to gun carriages, we will only now observe that it has been so applied and successfully worked. We hope shortly to place the details of this application before our readers, together with the results of some practical trials which have lately been made.

HOT BLAST STOVE AT THE THORNABY IRONWORKS.

THE annexed engraving illustrates a novel form of hot blast stove which has been used for some time at the Thornaby Ironworks, Stockton-on-Tees. In the Cleveland district, where economy in working is studied as much, or perhaps more, than in most other iron producing districts, it has been found that with an increase of every 100deg. in the temperature of the blast above 750deg., a saving of about 1 cwt. of coke on the ton of iron made has been effected. Hence, in order to produce pig iron as economically as possible, it has become necessary to provide a very large and expensive plant of heating stoves. Mr. Whitwell's hot blast stove contains no cast-iron pipes, but is constructed of firebrick, ganister, or other refractory material—enclosed in cast iron—which is capable of enduring the greatest heat that can be obtained from the combustion of the blast furnace gas, and hence all wear and tear of cast-iron stove pipies is saved, whilst a temperature of blast is obtained which would be probably unattainable under any circumstances in any stove constructed with cast-iron pipes. In working this apparatus two similar stoves are used, which by preference are of a circular form, and whilst the blast is being heated in the one the other is being heated by the blast furnace gas, which is introduced at the gas inlet B; the air necessary to effect combustion being introduced through the Argand burner K also at the air inlet L; in this instance the air is heated to a high temperature before meeting the gas, and thus induces a most intense combustion.

The gases ascend and descend the walls of the stove, passing under the central longitudinal wall in their course to the chimney, as at H and I; the products of combustion, after imparting their heat to the brickwork, pass off to the chimney at D. When a sufficient temperature has been obtained the process is reversed, the blast is introduced into the stove just heated, and issues therefrom at a temperature nearly equal to that already communicated to the brickwork by the burning gas, passing, in fact, over the self-same surfaces over which the gas has already travelled. The cold blast is introduced at C at that end of the stove whence the products of combustion have previously been passing at a low temperature to the chimney, by which means the blast is gradually heated, so that when it reaches that part of the stove which is red hot, it has attained to nearly the same temperature, and issues from the stove as above mentioned at a red heat. A distinguishing feature of these stoves, however, is that they may be cleaned from the dust deposited on the

Digitized by Google

heating surfaces by the gas, without being cooled down, and without it being necessary to enter them: for this purpose doors or valves E, protected by brickwork are placed at the top and at the sides of the stoves, and by opening those at the top the dust can be scraped from the heating surfaces and removed by the bottom valves F, without any loss of time. Hence it is not necessary to purify the gas before using it. The valves are so arranged as to allow sufficient air to be admitted to burn the gas perfectly, by which means the gas is consumed with great economy; for, whereas in cast-iron pipe stoves the gas issues from the chimney at a heat of nearly 2,000deg., in these stoves the products of combustion pass into the chimney at a temperature of from 500deg. to 700deg., the difference being absorbed by the heating surfaces, and returned to the blast furnace in the heated blast. The construction of this stove will be readily understood from our engravings. The principle on which the apparatus acts is not new, but the details and general arrangements are novel and constitute features of much excellence. The "Engineer," from which paper we obtain our information, states that a pair of these stoves are now working at the Thornaby Ironworks, Stockton-on-Tees. They are cleaned every two months, and this is accomplished in four hours and a-half, whilst red hot, by means of wire brushes and rakes. The ordinary stoves require thirty-six hours to cool, clean, and get up heats again, thus producing irregularity in the working of the furnaces. The patentee has arranged with Messrs. Siemens and Cowper for the use of their patents in this hot blast stove.

THE EMPEROR NAPOLEON III. ON THE VOLTAIC PILE.

It is certainly not generally known that the present Emperor of the French is the author of a very able essay on the voltaic pile. It will be found published in the "Comptes Rendus" for 1843, vol. xvi., pp. 1180—1. At the time of its publication it had great merit, and even now will be found to possess much interest. We give it here all the more willingly as the paper in question is not to be found in the Emperor's collected works. The essay came before the Academy of Sciences in the form of a letter to Arago, dated the 23rd of April, 1843, from the Fortress of Ham, where he was then imprisoned for his attempt at Boulogne. The academicians observe in a note that "though Prince Napoleon was preceded by M. Becquerel in the construction of a pile composed of elements consisting of only one metal, yet they feel they ought to publish the letter," adding that "the clearness of the reasoning and of the results will justify our determination in the eyes of everyone."

The Prince's essay is as follows:—The source of galvanic electricity has been attributed by Volta to the contact of two dissimilar metals. Davy partook of this opinion, but other men of science, and amongst them the illustrious Faraday, have expressed the opinion that the chemical decomposition of the metals was the only cause of the electricity. Adopting this last hypothesis I have reasoned as follows:—As in the pile there is never more than one of the two metals that is oxidized, if the electricity is only due to the chemical action, the second metal ought to play in this connection but a secondary part. What is this part? It is, I think, that of attracting and conducting the electricity developed by the first in a manner analogous to that going on in the ordinary electric machine. As a fact, in the latter the electricity disengaged by the friction traverses an imperfect conducting medium, which is the air, and is attracted and conducted by a perfect conductor, which is the metal. In the pile the electricity produced by the oxidation of any given metal traverses an imperfect conducting medium, which is the liquid, and is gathered up and transmitted by a perfect conductor, which is the adjacent metal.

This idea appeared so clear and simple to me that I sought for a means of proving its exactness by experiment, and I further reasoned as follows:—If it be true that one of the two metals employed in the pile only serves as a conductor, it can be replaced by metal identical with that being oxidized, provided that it be plunged into a liquid that, while permitting the passage of the electricity, does not attack that metal. Experiment confirmed my previsions. I constructed two couples, according to the principle of the constant piles of Daniell, but with one metal. I immersed a copper cylinder into a liquid consisting of water and nitric acid, the whole being contained in a porous earthenware tube. This tube was surrounded with another copper cylinder immersed in water acidulated with sulphuric acid, a mixture that does not attack copper. Having formed the communications in the usual way, I decomposed with this pile of two couples some dissolved iodide of potassium, and having placed at the extremities of the piles two copper plates dipping into a solution of the sulphate of the same metal, I gathered at the pile communicating with the copper attached a deposit of copper.

I made a second experiment with zinc alone. I poured into a porous tube a mixture of water and sulphuric acid, and I surrounded this tube with another cylinder of zinc, immersed in pure tepid water, with two similar couples. I equally decomposed iodide of potassium, and I obtained, by taking the necessary precautions, a deposit of copper at the pile in connection with the zinc attached as previously. Finally, I reversed the usual order of the metals, and placed the copper into the centre of a vessel plunging into water and nitric acid, and I surrounded the porous tube with a zinc cylinder immersed in pure water. I thus obtained a rather strong pile. I should have wished to have been able to measure with care the different strengths of the electric currents produced, but it was impossible for me to do this for want of a galvanometer. My efforts to construct one did not succeed, as the magnetized needles were always deviated by the attraction of the iron bars surrounding my windows. Nevertheless, from the experiments I was able to make, it seemed to me demonstrated:—

1. That in the pile the cause of the electricity is purely chemical, as two metals are not necessary to produce a current.

2. That the metal which is not oxidized only serves to transmit the electricity.

3. That each metal is positive or negative (anode or cathode) to itself or to others, according to the nature of the liquid into which it is plunged.

METAL FOR FRASER GUNS.

We last week briefly noticed the circumstance that Colonel Campbell had received permission to utilize some of the old cast-iron guns of small calibre for the manufacture of Fraser guns. This is a very satisfactory arrangement, inasmuch as it disposes of an immense stock of ordnance materials which have been accumulating for the past twenty or thirty years in Woolwich Arsenal, and with which the open spaces fronting the stores and factories are now encumbered. It appears that about 2,000 tons weight of the smaller calibres are now being transferred to the Royal Gun Factories to be worked up by the Bessemer process into malleable blocks and coils for the above purpose. There are also other guns to be utilized in this way; in fact it has been ascertained that the waste stock of old material will supply the factories for twelve or fourteen years, independently of the large number of guns conceded to Major Palliser for the purpose of conversion on his principle. Colonel Campbell, through whose suggestion the War Department has sanctioned the introduction of the system, is so well satisfied with the results hitherto obtained by the initiatory trials, that the number of puddling furnaces is to be increased from three to five, and a number of efficient puddlers have been added to the establishment. Besides the old guns, Colonel Campbell intends using up the whole of the refuse, such as the old carronades of the time of George I., and the useless spherical and broken shot and shell amassed in various parts of the Arsenal. With five furnaces it is stated that ten tons of malleable iron of very superior quality will be produced daily at the rate, including all expenses, of about £8 per ton. We can but regard this as a step in the right direction, and a sensible method of dealing with what has hitherto been deemed waste.

"BESSEMERISING" AND THE NITRATE STEEL PROCESS.

Just as the Messrs. Moses, the great trouser-makers, have long been known to keep their own poet, so have the Messrs. Bessemer, the great steel makers, long been known to keep their own leading article writer. And in both these cases, and with the same prosaic end in view, the result has been the publication of a great mass of poetical prose and prosaic poetry. Now reflection will show the impartial observer that Mr. Bessemer's investing in what some might deem a luxury was a particularly natural step on his part. Upon the whole, we consider it probable that a few of the many investments Mr. Bessemer has made during his career have been more promising. It is now many years ago that Mr. Bessemer discovered the great use of puffing——air into materials softened by heat, or soft by nature. By an obvious train of thought Mr. Bessemer looks upon the public as a multitude of pigs, simply boiling to be converted into Christian Bessemer metal. We break no confidence, therefore, when we state as a fact, of which many are already aware, that Mr. Bessemer has long ago purchased, set up, and started, a very powerful blowing or puffing engine, embodying all the latest Yankee dodges—in fact, we believe the choicest production of an American maker. And with all the energy of its remarkable country does this remarkable engine work. It does occasionally throw about a good deal of dirty grease—possibly due to too much lubrication—and its tenter has also to be very careful in handling it. But, upon the whole, it yields a very high percentage of puffing duty, and may be looked upon as the most powerful Bessemer Blowing Engine ever erected on a bed plate. Such are the results of the march of intellect and of the applications of science and invention to the wants of the age. At a less advanced period in the world's history Mr. Bessemer might have been contented with blowing his own trumpet. But, no. With a true appreciation of the value of the division of labour and of the utilization of power, he applies a blowing engine to the trumpet of fame. Or, to drop the metaphor, Mr. Bessemer no doubt considers, like the poet, with regard to the end "of all fame—'tis but to fill a certain portion of uncertain paper." And, accordingly, it is filled with accounts of the Bessemer process, and Bessemer metal, and Bessemer rails, and Bessemer ingots, and Bessemer converters, and Mr. Bessemer's school-days, and Bessemer plate, and Bessemer rails again, again, and so on, *ad infinitum*.

But if the Bessemer Blowing Engine works "sweet" in effecting, or in attempting to effect, Bessemer conversions, its action is not pleasant with regard to other processes of steel making. A fortnight ago we were so foolhardy as to venture guardedly to express some hopefulness as to the future of a certain process for making steel and refining iron for puddling purposes by the use of nitrate of soda. The Bessemer Blowing Engine was down upon us at once. Apart from a playful little splashing about of grease, no doubt greatly due to the extremely rapid reciprocations of its brass details, and apart also from some more or less ingenious little "conversions" of our words (easily detected by anyone caring to take the trouble) Bessemer Blowing Engine's objections resolve themselves into:—1. That nitrate of soda, if used for making steel and refining iron, would be very costly. 2. That the limited supply of nitrates ought to have shown us "the immediate probability of a rise in the market value of soda, if wanted in such enormous masses as the iron trade of the Cleveland district would demand."

1. But in the first place, we must remind the Bessemer Blowing Engine that, in observing that, as "a ton of nitrate costs £10," 8 per cent. being required, the outlay of 16s. per ton of pig iron "for the nitrate alone," would show "the immediate probability of a rise in the market value of soda;" it forgets its *protege's*—or its protector's (?)—as to this question we are as puzzled as in telling the head from the tail of a hairy terrier—average charges of £2 10s. per ton for royalty alone. Assuming Mr. Hargreave's ultimate success, Mr. Hargreaves would be able to use iron costing 16s. to 20s. per ton less than anything that Mr. Bessemer can use, and possibly obtain—certainly with less cost of plant and labour—a larger yield and a better quality of steel.

2. As to the supply of the nitrate of soda being "limited," the fact is that the supply is practically exhaustless. One single South American source of supply has been estimated by Bollaert, in his work on Peru, as amounting to more than sixty-three millions of tons. The mode in which it is manufactured and conveyed to the Peruvian coast for shipment is still of the rudest description, and a greater demand would no doubt be attended with a diminished price. A proof of this is to be found in the fact that though the demand for it was never greater than at present, its price was never lower. It is extensively used as a manure and in the manufacture of nitric and sulphuric acids, in the latter of which manufactures alone 14,000 tons annually are consumed. The last annual Board of Trade returns of imports extend down to the year 1866; those for 1867 will only be published within a month. Taking the year 1866, therefore, we find that more than 48,000 tons of nitrate of soda were imported into Britain during that year. In spite, therefore, of the Bessemer Blowing Engine, the supply may be considered as being practically exhaustless as the iron and coal of this country; and if Mr. Hargreaves can as easily overcome his practical difficulties as we have met the Bessemer Blowing Engine's airy objections, Mr. Hargreaves will yet be a very wealthy man.—"The Engineer."

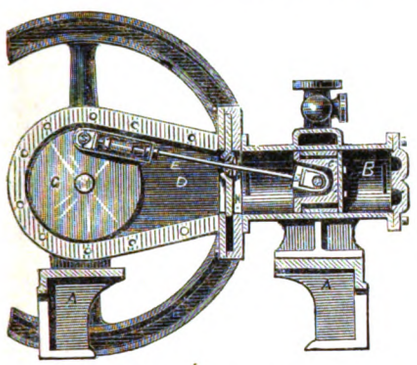
BAILEY'S STEAM ENGINE.

THE essential requisites in a steam engine in order to excel in the present advanced stage of its improvement, are lightness, strength, compactness, and simplicity, so that it can be easily transported, occupy but little space, be readily put up and operated by engineers of ordinary capacity and limited experience. The working parts should be few and durable, and protected from the injurious effects of dust and dirt. In the engine herewith represented the elements above mentioned seem to be combined in an eminent degree. The crank of this engine, with its connecting rod, &c., is enclosed in a steam-tight head, so arranged as to form an extension from one end of the cylinder in which the piston works, and to this piston the connecting rod is directly pivoted and the opposite end actuating the fly-wheel. To close the communication between the cylinder and the hollow head, a transverse slide is fitted with a rocking block through which the connecting rod passes, the combined action of which provides for the free motion of the connecting rod, and, at the same time, forming a sufficiently steam-tight division between the cylinder and head.

Our engraving shows a vertical section of the working parts of Bailey's engine. Upon the standards A A is secured a cylinder with its attached head, and they support the valves, &c., necessary for the action of the engine. A piston C is fitted to the cylinder, and is made of sufficient length to form in itself a guide in its reciprocating motion. One end of this piston is hollowed out to receive one end of the connecting rod which is pivoted to it, the opposite end of the rod being attached to the wrist pin S of the disc G which is keyed to the shaft of th



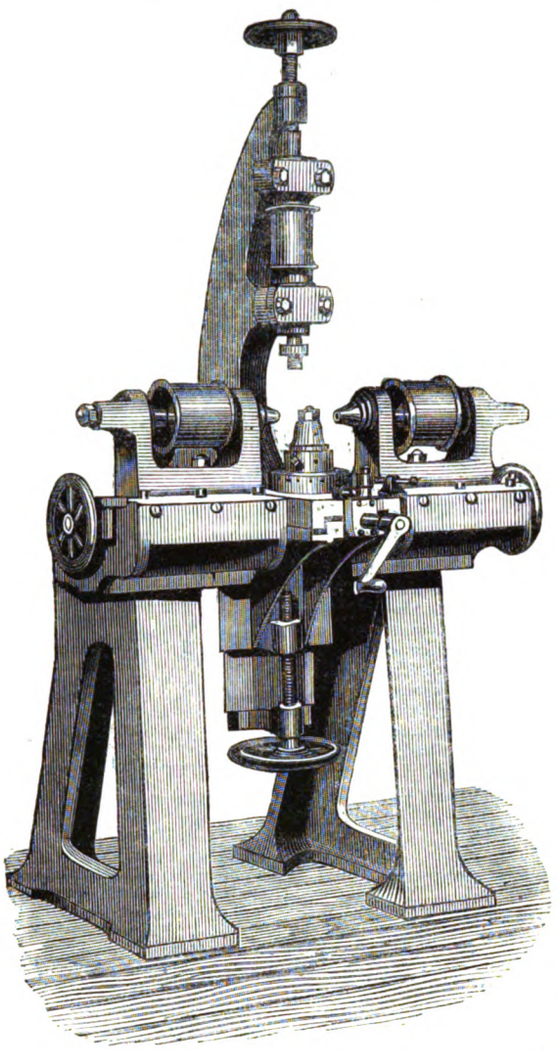
fly-wheel. This disc is enclosed in the extension D of the cylinder, and the form of this extension is such as to correspond to the travel of the connecting rod, E. This arrangement of parts not only dispenses with a piston rod, cross-head &c., but forms a steady-working and compact form of engine, having its crank and connecting rod concealed from view and injury. To close the communication between the forward end of the cylinder B and the head D so as to exclude the steam which would otherwise fill it, and would consequently be exhausted with every stroke of the cylinder, proving a loss, a slide H is fitted in a case, so that a free vertical motion is given to the slide by the motion of the connecting rod. Through a central opening of this slide the connecting rod passes; and to form a steam-tight joint the rod passes through a rocking block I which has a curved form of face to correspond with a similar curvature made in the slide.

By the motion induced by the connecting rod the slide works up and down, and the block works in its seat in an oscillating manner, presenting no impediment to the operation of the rod, and by the combined action of the slide and rocking-block the connecting rod has free passage and play in a sufficient steam-tight manner without the aid of a stuffing box; but inasmuch as the head D forms a steam-tight inclosure, it is by no means necessary that the slide H or the block I be otherwise than a good working fit, and packing may be dispensed with. It will be observed that the steam-tight extension D of the cylinder encloses all the principal working parts, which serves to keep them well lubricated, and prevents the ingress of dust, dirt, or other foreign substances. This makes it especially applicable to the American street cars, and we understand that one is now being introduced into a car in New York. The "American Gaslight Journal," to which paper we are indebted for all particulars, states that this engine was patented in March last year, and is on sale at 42, Day-street, New York, where it appears likely to be in good demand.

THE number of visitors at the South Kensington Museum during the week ending February 8, were:—On Monday, Tuesday, and Saturday (free), from 10 a.m. to 10 p.m., 10,898; Wednesday, Thursday, and Friday (admission 6d.), from 10 a.m. till 4 p.m., 1,418—total, 12,316. Average of corresponding week in former years, 10,077. Total from the opening of the museum, 7,186,250.

NUT SHAPING MACHINE.

BY MESSRS. KENDALL AND GENT.



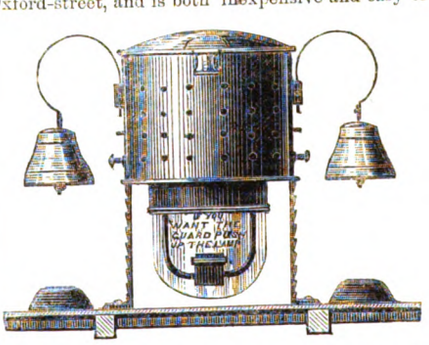
NUT-SHAPING MACHINE.

THE neat little machine illustrated above has been designed for shaping nuts, bolt heads, and other articles having any number of sides. Three varieties of the machine are manufactured—single, double, and treble. That illustrated is a treble machine. The article to be shaped is fixed by a suitable mandril to the sliding table, the position of which is regulated by a hand-wheel and screw. The three cutters are driven by the band-wheels seen to the right and left and at the top of the machine. The heads are severally adjustable, so as to be easily brought to bear and act simultaneously on the object on the mandril. The form of cutter found best to answer the purpose is the flat, or "fly" cutter, modified in various ways as may be necessary. By one run up of the horizontal slide the three faces are finished, the surface left by the cutters being beautifully delicate, the slight ring marks left by the cutters giving a kind of watered surface to the material. The faces are changed for others by turning round the dividing apparatus below the mandril, so that the point of the handle shown may drop into the proper hole in the rim of the indexed dividing wheels; this handle is held in its place by a coiled spring. The various heads of the machine are easily driven, and the machine is usually worked by a youth; the saving in files and workmen's wages over the hand system of finishing is, we understand, great. The use of these machines is rapidly extending, and they have been found especially serviceable to brass workers. We should add that this machine is manufactured by Messrs. Kendall and Gent, of the Victoria Works, Salford.

THE number of visitors at the Patent Office, South Kensington, for the week ending Feb. 8, was 3,923; total number since the opening of the museum free daily (12th May, 1858), 1,243,132.

RAILWAY PASSENGER SIGNAL.

THE growing necessity for a means of communication between the passengers and guards of railway trains, and the probability that Government will shortly take action in the matter, have lately served to stimulate inventors in this direction. A simple apparatus for train signalling has just been brought under our notice, and is shown in the accompaning engraving. It is the invention of Mr. Joseph Offord, of 79, Wells-street, Oxford-street, and is both inexpensive and easy of



application. The ordinary lamp, which already exists in each compartment, is made available with the addition of one or more bells, attached by springs to the protector, as now used with every lamp. By means of two springs and ratchets the lamp rises by anyone gently pushing at the bottom of the glass, and the bells leave the small blocks on which they rest, and ring rapidly until the train is stopped, or the lamp lowered, which can only be done from the roof. The signal needs no attention and is always ready for action, and it cannot be tampered with, without its being discovered who has done so. The spot where atten-

Digitized by Google

tion is required is at once seen, either day or night, without additional lights, and unimpeded by curves or lights from the windows. Among other advantages, this signal would be plainly seen at all the stations, and it cannot be prevented from acting. Small engravings, showing its action, could be posted in each carriage. But it is so simple that it cannot get out of order, and anyone can understand it, and it is of universal application. If a guard were in the next carriage to the engine, and always on the lookout, from a raised glass compartment, in any case of danger he would at once see and could act simultaneously with the driver, and no doubt prevent many serious and costly accidents.

THE PATENT CONCRETE STONE IN AUSTRALIA.

ONLY a few months since we drew the attention of our readers to the circumstance that the manufacture of concrete stone, under Mr. Ransome's patent, was being introduced into India. It is with much pleasure we observe, by the Australian papers, that it is now being carried out in Melbourne. A company has been formed for the purpose of producing this material, which is made in the same way as here in England. The process of manufacture is well known to our readers, so that we need only observe that sand and silicate of soda are mixed together, moulded, and afterwards hardened by immersion in a solution of chloride of calcium. A number of the leading architects of Melbourne recently met at the offices of the company in that city, and witnessed the manufacture of the patent stone, and inspected a number of specimens. The results of the experiments were most satisfactory, and showed the perfect adaptability of the stone for building purposes. We are glad to observe the gradual extension of this important manufacture, which is based upon sound scientific principles, and we congratulate Mr. Ransome upon the success which is now resulting from the years of patient labour he has bestowed upon the subject.

THE GOURAMI FISH.

WE call the attention of ourreadors and the public to the offer, by Mr. Henry Lee, F.L.S., of a prize or reward of £20 to the person who shall first take to him, at the office of "Land and Water," four or more living specimens, male and female, of the Mauritius fish Gourami. The Gourami is so highly esteemed as an article of food that its flavour is by some thought even more delicious than that of the salmon or turbot, and it would, without doubt, be a great and useful addition to the food-fish of Great Britain. Even before the year 1830 various attempts were made to introduce it to foreign countries. Some of these were successful, others the contrary; but there is every reason to believe that, by careful attention during transit, the Gourami may, without any great difficulty, be safely brought to England. It is very hardy, and will live for a long time in rather impure water. It is thought that specimens of this fish, about four inches long, are those most likely to bear the voyage well. Dr. Meller, director of the Royal Botanical Gardens, Mauritius, has kindly promised to supply as many as he may think desirable to anyone who will seriously undertake the care of them. We sincerely hope that Mr. Lee's liberal offer may be responded to, and that it may lead to the acclimatization in our waters of a very valuable fish. If our expectations are verified, before this time next year our readers may be able to study the habits of the Gourami in one of Mr. Buckland's tanks at the Horticultural Gardens.

Correspondence.

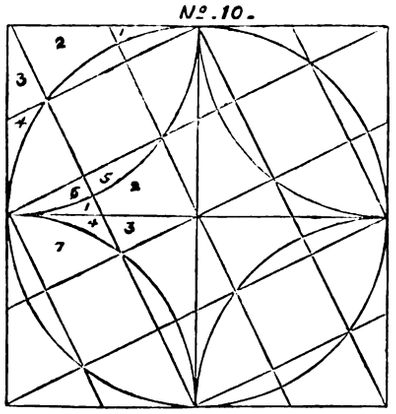
THE SQUARE OF THE CIRCLE, AND THE GREAT PYRAMID OF GIZEH.

LETTER X.

TO THE EDITOR OF THE "MECHANICS' MAGAZINE."

SIR,—Your correspondents "A. W." and P. H. Van der Weyde, M.D., whose letters appear in your issue of January 31, have in their attitude so completely assumed the well-known weak position in law, "No case, abuse the plaintiff's attorney," that it is almost a work of supererogation to slay them with the weapons which they have placed in my hands. It may be necessary to say that the method adopted by both of them is that process of estimating the length of a circle by polygons interior to and exterior of it. The method is not theirs but was originated by honest old Archimedes, of Syracuse, who never claimed for his rule anything more than an approximation to the length of a circle, nor did he employ the endless decimal method, which is the egregious folly and passion of the present day, and which has been so well handled by your correspondent Mr. Joseph A. Nicholson in his letter No. III., in your issue of January 31. The approximation of Archimedes was diameter 7, circumference 22. My ratio, a ratio founded on the most powerfully complete geometric demonstration (see diagrams in Letter III., of October 18, 1867), that the area of any circle is 4-5ths of its tangent square, its diameter 5, circumference 16. It has been already allowed by nearly all my geometrical friends that the proofs I have adduced in your pages of these values are, if possible, a more indisputably exact quadrature of the whole circle than the quadrature by Hippocrates, of Chios, of his famous lines which I gave in my letter No. VIII. He grasps a portion of the interior of a semicircle having for its diameter the hypotenuse of a right-angled triangle to gauge by it the lines of two semicircles on the two sides of the right angle of the triangle. I, on the contrary, go outside of

No. 10.



and grasp the whole circle upon the hypotenuse of a right-angled triangle, and compare it with the squares on the two sides of the right angle of the triangle which are relatively to one another in the only proportion of which the circle acting upon itself in its square disposition admits (see diagram 6, Letter III.) I am thus, by the unanswerable proposition 47, Book 1 of Euclid, enabled to weigh all these areas relatively to one another in a scale finer even than the hydrostatic balance of Archimedes.

"A. W.," presuming very improperly that I admit approximative mathematical decimal tables to record exact truth, proceeds to found calculations of his own upon them, from which he elicits the following very remarkable result, which, with consummate coolness, he proceeds to put in my mouth, as thus:—"Of course, all the circumscribed polygons of more than fourteen sides have, according to Mr. Harvey, smaller areas than their circles, which is a clear demonstration of the incorrectness of Mr. Harvey's formula." Now, I am not responsible for the improper use here by "A. W." of my name to father his own acts. But I would ask your readers to ascertain for themselves the value of that method, or of the calculations founded on it, which can bring a circumscribed polygon of any number of sides within the circle which it circumscribes.

P. H. Van der Weyde, after misquoting the figures of Mr. James Smith, of Liverpool, and the discussion between him, Professor A. de Morgan, and Sir Rowan Hamilton, from the London "Athenæum," proceeds:—"Mr. Harvey goes further than any of them; the circumference of his circle being 3 and 1-5th diameters, lays outside the circumscribed polygon of sixteen sides." To which of these infallible dogmatists of a so-called infallible decimal theory, which has the extraordinary property of making straight lines tangential of and drawn outside of a circle come within that circle, are we to award the palm of immortality, he of fourteen sides or he of sixteen? Truly, the end is worse than the beginning. If the words "absurd," &c., are to be used, to whom, pray, shall we apply them? I leave the judgment with your readers.

As the truth of my theorem on the square of the circle, explained in your pages in these ten letters, is already so generally admitted as to render its adoption an acknowledged scientific fact merely a work of time, I will terminate with this letter both my lucubrations on it and on the Great Pyramid, because I judge from the letter of Mr. Thomas C. Haines, in your issue of January 31, that these last have not sufficient interest for your readers. In deference, however, to his request that I should do so, I produce diagram No. 10 as self-explanatory evidence of the method by which the 4 spandrils E and the square F G H I (see diagram 7 in my letter No. III., in your issue of October 18, 1867), can be shown to be together equal to two squares of the value of F G H I, and therefore of course equal to one another. The arithmetical digits 1 2 3 4 point out the divisions of one spandril exterior of the circle and brought together within the circle so as to form with a quarter of the central square 5 6 7 one quarter of two whole squares equal to the central square F G H I. I fancy this demonstration (one of many) will reach the apprehension of your readers who have previously believed that in my former demonstrations I assumed that which was indemonstrable. If they had studied Aristotle's "Organon," Book 1, cap. 9, they would not have hesitated to admit the force of my reasoning from quantities common to two descriptions of genus. Aristotle uses it expressly to explain the quadrature of the circle, which he states had been made by Bryso, whose works and whose demonstration of his discovery have not reached our times.

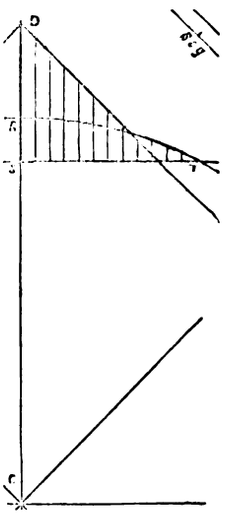
With many thanks for your courtesy in giving place to these geometrical diversions of mine.—I am, Sir, yours, &c., WILLIAM HARVEY.

London, February 7.

LETTER IV.

SIR,—The geometrical proposition which I presented in Letter II., on the 17th ult., had for its object to prove the area of the circle from the given circumference. The object of the present letter is a geometrical proof of the circumference from the given area, and though the proof I have to offer is not so geometrically pure as the previous one, it will, I hope, be exact, and a starting point from which to get at the circumference by working the previous problem backwards.

In my first letter it was shown that the area of parallels depended on the length of line, however placed, the combined length being the measure of the area, though the line might be all on one side and only a point on the other. It is on this principle that I propose to test a square and a circle's equality. Mr. Hayden has justly remarked that an equal circle and square drawn from the same centre will cut off each from each, an equal portion in the form of corner and segment, for the remainder being common of course the whole must be equal. With this view I have placed, for convenience of proof, a segment beneath a corner, divided both by the



same parallel lines, and measured the total length contained in each division separately, and adopted the division at the point where they were equal.

As a proof of the sensitiveness of this arrangement (the true division is a fine space between two nearly touching lines) I have carefully, by lens and screw compass, measured each, and the space between them. The outer line gives a preponderance of segment over corner of 1¼in., the inner line of over 6-8ths in favour of corner over segment, and the space between them a fraction of about 1-24in. to corner, due to curve. Only one-half of the corner and segment is shown in the diagram, but in my measurements I have taken them complete

Let S C be the half diameter of a square.
D C „ half diagonal of ditto.
R C „ the radius of the circle.
D „ the half corner.
and R S T „ the half segment (transposed).

Then the half diagonal D C divided into eleven parts, and one of those parts R S added to S C, the half square will give the radius R C, and the inside edge of that circular line will be the true equivalent to the square. Now, let us refer to my former proposition (January 17), and consider this circle and square as there represented by *o* and *s s s s*; by working that problem backwards we shall arrive at the half circumference of the circle A P, which will be the circumference sought, and establish the rule that the diagonal of a square divided into eleven parts, and one of those parts added to the diameter of the square, will give the diameter of the corresponding circle; on which basis digital calculations may be made, but which I do not intend at present

Digitized by Google

to follow. I may here add a corrective to the arbitrary rule given by Mr. W. Hayden for finding the circumference. Mr. H.'s rule is three diameters, and the versed sine or depth of the segment of a fourth of the circle—too little; but three diameters and twice the depth of the segment of which the radius is the chord is too much. The difference between the two, however, is a very close approximation to absolute truth, if not completely so. I am obliged to Mr. Thomas Scutt for the notice he has taken in your last number but one of my previous proposition, and he will excuse me for saying that if he admits it to be correctly "parallelogramized," he admits it to be squared, as there is certainly no difficulty in getting from one to the other, and which was done in the same problem by the XIII. prop. of the VI. Book of Euclid, which gives "the mean proportional line" or square. He says the proportions have been known long ago, which I take his word for, though I never met with them in that form, but I expect every proportion and property of a square and circle is known and has been long ago, but what was wanting was a proof—a clear turning by indisputable geometrical reasoning of a circle into a straight-lined figure, whether triangle, parallelogram, polygon, or what not. This my problem has done, and it was unknown to Euclid; but if I have already been anticipated I shall feel obliged to Mr. Scutt, or any other correspondent, dispelling the illusion of discovery by referring me to any accessible publication where it may be verified. Before closing, I for one beg to protest against the letter of the ex-professor Van der Weyde, who appears to think it sacrilege for any but professors to approach an intricate subjects (often made so by excess of science), and illogically condemns not only Mr. Harvey for being wrong but your other correspondents for putting him right. Mr. Harvey's letters are very interesting, although he still adheres to certain errors (but the world learns as much by errors as truths), and out of them may yet perhaps arise a subject far more practically important than the squaring of the circle, namely, the annotation of our numerals. By the present arrangement of decimals, $\frac{1}{3}$ $\frac{1}{6}$ $\frac{1}{7}$ and $\frac{1}{9}$ and their compounds run off at once into interminable figures; $\frac{1}{2}$ $\frac{1}{4}$ $\frac{1}{5}$ and $\frac{1}{8}$ are manageable and become finite, but mixed they commence a desperate struggle, like the 35 absurd decimals of Ludolf Van Ceuber.—I am, Sir, yours, &c.,

February 9. JOSEPH A. NICHOLSON.

SIR,—In reply to Mr. Harvey I beg briefly to observe that the "Nautical Almanack," not the "Nautical Magazine," is accepted by naval officers as the production of men of the greatest mathematical attainments. It is accepted, also, under a conviction that the relative positions of the celestial bodies are determined by Kepler's laws of planetary motions; in the computations of which the value of trigonometrical lines are based upon the long accepted ratio of the circle to its diameter.—I am, Sir, yours, &c.,

COMMANDER, R.N.

Pembroke, February 8.

TO CORRESPONDENTS.

THE MECHANICS' MAGAZINE is sent post-free to subscribers of £1 1s. 8d. yearly, or 10s. 10d. half-yearly payable in advance.

All literary communications should be addressed to the Editor of the MECHANICS' MAGAZINE. Letters relating to the advertising and publishing departments should be addressed to the publisher, Mr. R. Smiles, MECHANICS' MAGAZINE Office, 166, Fleet-street, London.

To insure insertion in the following number, advertisements should reach the office not later than 5 o'clock on Thursday evening.

We must absolutely decline attending to any communications unaccompanied by the name and address of the writer, not necessarily for insertion, but as a proof of good faith.—ED. M. M.

Advertisements are inserted in the MECHANICS' MAGAZINE at the rate of 6d. per line, or 5d. per line for 13 insertions, or 4d. per line for 26 insertions. Each line consists of about 10 words. Woodcuts are charged at the same rate as type. Special arrangements made for large advertisements.

RECEIVED.—F. W. P.—H. D. R.—S. S.—W. R.—T. C.—J. H.—A. C.—T. A. W.—W. H.—G. E. P.—T. M.—J. B. T.—J. N.—R. J.—J. N.—E. B. M.—G. W. H.—Messrs. G. K. and Co.—W. H. H.—K. M.—C. E.—J. A. N.—J. T. D.—Messrs. C. M. and Co.—T. A. W.—T. C.—J. B.—F. R. S.—G. H.—M. T. P.—R. B.—C. D. F.—J. R.

Meetings for the Week.

MON.—Royal Institute of British Architects.—George Grove, Esq., on "The Exploration of Jerusalem and the Holy Land," at 8 p.m.

Society of Engineers.—Dr. Cullen on "The Panama Railroad," and on "The Darien Ship Canal," at 7.30 p.m.

TUES.—Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

The Institution of Civil Engineers.—Mr. W. J. M'Alpine, on "The Supporting Power of Piles, and on the Pneumatic Process of Driving Iron Columns, as Practised in America," at 8 p.m.

THURS.—Royal Institution.—Professor Tyndall on "The Discoveries of Faraday," at 3 p.m.

FRI. — Royal Institution. — Rev. M. W. Mayow, on "Macbeth and Hamlet as the Greatest Works of Shakespeare," at 8 p.m.

SAT.—Royal Institution.—Professor Roscoe on "The Non-Metallic Elements," at 3 p.m.

Naval, Military, and Gunnery Items.

CAPTAIN FREDERICK SIDNEY BOULTON has been elected surveyor of Lloyd's Salvage Association for the port of London, rendered vacant by the death of Captain F. J. Steward.

MR. W. SCAMP, C.E., the late deputy-director of engineering and architectural works to the Admiralty, who has retired with a full-pay superannuation, after a lengthened period of service, transacted his last official business at Somerset House on Wednesday week.

MESSRS. NAPIER AND SONS, of the Clyde, are building for the Dutch Government a steam ram of about 3,000 tons and a turret ship of 2,000 tons. They are intended to be fitted with Skinner's steering apparatus, similar to that successfully tested by her Majesty's ships "Industry" and "Supply," by which one man alone can steer in the most boisterous weather with ease, and free from danger.

THE Belgian Minister of Public Works has concluded a contract with Messrs. Tait and Co., of London, for the establishment of a monthly service of steamers between Antwerp and Rio de Janeiro, Monte Video, and Buenos Ayres, with permission to stop at Lisbon, St. Vincent, Pernambuco, and Bahia. The passage from Ostend to Rio is expected to be effected in twenty-four days, and the first departure from Ostend is to be made on the 16th of March.

THE "Bankers' Gazette" of St. Petersburg announces that in the great arms factory of Toula great activity prevails at this moment. The establisbment has already prepared 15,000 needle-guns, and hopes are entertained that 100,000 will be furnished before the end of the year. These muskets appear to leave nothing to be desired; a soldier can fire seventeen shots a minute if the cartridges are placed on a table beside him, and nine when he has to take them from his cartouche-box.

THE Board of Trade having been requested to state what they deem to be a square-rigged vessel, have given notice to superintendents of mercantile marine offices, and to examiners of candidates for masters' and mates' certificates of competency, that they are advised that full-rigged ships, barques, brigs, and brigantines should be treated and referred to as square-rigged vessels, and that other ships, such as topsail schooners, fore and aft schooners, cutters, sloops, &c., should be treated and referred to as fore and aft rigged vessels.

THE latest advices from Abyssinia state that the lighting of the coast is now complete. The wells, on the American principle, yield a good supply of water, and troops are being rapidly pushed forward into the interior. The native followers are being sent back to India, which must be looked on as favourable, considering that many of these men have done little but eat their dinners since their arrival.

IMPROVEMENTS and alterations in the bakery of the Commissariat Department at Aldershot, now being made, consequent on the introduction of steam for bread-making, necessitated the removal of a chimney shaft 75ft. in height, and which for several years had been in an unsafe condition. The removal of the shaft has just been safely effected under the superintendence of Colonel Laffan, commanding Royal Engineer. A few bricks being taken out, 18oz. of powder in one ounce packets were placed in the spaces, and being fired, the shaft toppled over in beautiful style, and in the direction intended.

THE new T-pier about to be erected in Woolwich Arsenal is ordered to be commenced without further delay. It is intended to facilitate the shipment of the heavy ordnance, and will be fitted with cranes capable of hoisting 30 tons weight. The pier, with its T-platform, will extend 300ft. towards the bed of the Thames, from the wharf fronting the Royal gun factories, and will be 25ft. broad, so as to contain three lines of tramway. The head of the pier will be 100ft. in length, constructed so as to admit of its being lengthened, should an increased demand for shipping space arise. The principal portions of the pier are to be of iron, the cost of which has been estimated at upwards of £20,000. It will be built by contract, under the supervision of the works department of the Royal Engineers.

As speed is really the primary consideration with enarmoured vessels, the subjoined table will show xactly what has been accomplished by the "Danae" in this respect, the first and second trials having been made with the regular trial steam coal, and the third trial with the ordinary quality of coal as supplied for sea service. All were full boiler power trials:—

	Dec. 19, 1867.	Jan. 23, 1868.	Jan. 24· 1868.
Mean speed of the ship, knots	13·172	12·872	12·588
Mean revolutions of engines	94·75	91·96	88·62
Indicated horse power	2088·35	1917·6	1715·29
Steam pressure on piston	26·554	19·448	18·053
Vacuum, mean	26·416	26·08	25·96
Mean draught of water	15ft. 1in. stern, 35in.	15ft. 4in. stern, 22in.	15ft. 3in. stern, 24in.
Trim of ship			

FROM the Clyde it is reported that Messrs. Scott and Co., of Greenock, have contracted with Messrs. Monies, Munro, and Co., to build for them a screw steamer of about 500 tons. The Glasgow and Londonderry Steampacket Company has purchased the paddle steamer "Bridgewater" from the Dublin and Liverpool Steam Navigation Company. The "Bridgewater" was built by Messrs. Caird and Co., Greenock, for Messrs. Burns' Glasgow and Belfast line of steamers; but she afterwards became a blockade runner under the name of the "Old Dominion." On the conclusion of the American war she was purchased by the Dublin and Liverpool Company, and now she has once more changed owners.

Miscellanea.

IN 1865 1,200,000 postage stamps got loose from letters and newspapers in the post offices, and 760,000 in 1866.

MR. HUDSON, of Castleacre, has resigned his seat at the Council of the Royal Agricultural Society, in consequence of his somewhat advanced age. Mr. Hudson is well known as an agriculturist throughout Great Britain.

ABOUT 700,000,000 letters now pass through the post offices in Great Britain and Ireland in the course of a year, and nearly 5,000,000 telegrams pass through the telegraph stations in the United Kingdom during the same period.

THE iron framework of the Universal Exhibition Palace of the Champ de Mars was sold by auction last Saturday for £60,000 to a society of contractors and builders—on which the "Figaro" remarks that the Exhibition has taken more time to disappear than to construct.

IT is computed that the cost of distilling water at Annesley Bay is 2s. a gallon, and the daily needs of the men and animals collected there average 40,000 gallons a day. Therefore, the water supply alone of that station is costing the British taxpayers at the rate of £1,520,000 a year. The "Pall Mall Gazette" calls these the waters of affliction.

IT appears, by the gold-mining records of the colony of Victoria, that twelve selected mines, with an aggregate paid-up capital of £145,382, have paid as profits, in the short period of from seven months to five years, no less a sum than £1,878,907. The history of mining has never before shown such extraordinary results.

AT a recent meeting of the Senatus Academicus of the University of St. Andrew's the degree of Doctor of Laws was conferred on the Rev. Patrick Bell, minister of Carnylie, the inventor of the reaping machine; and also on the Rev. Charles Clouston, minister at Sandwick, author of several works on meteorological science.

BEER has been successfully brewed at Shanghai. This and the arrival of the Celestial Embassy to Europe at the above port show how rapidly China is becoming civilized in the high sense in which we understand the term.

GREAT interest has been manifested in the colony of Melbourne on the subject of preserving superfluous meat, so as to make it an acceptable article in the English market. The problem to be solved is to get good beef and mutton, which at Melbourne are worth only 1½d. per lb., to the millions of English mouths which can get no beef at all. Two modes of preserving the meat have been tried—one in Sydney, and the other in Melbourne—both of which are said to have succeeded.

SIGNOR FUMAGALLI, in some sketches he is publishing in the "Annali di Medicina" of the careers of some distinguished surgeons, mentions, as a very remarkable coincidence, that the two founders of modern Italian surgery, Palletta and Scarpa, were both of humble birth; both remained unmarried, and, becoming very rich, continued to live a life of parsimony; lastly, having become well-nigh blind, in consequence of poring over books, both terminated their famous careers in the same year at the advanced age of eighty-four.

AMONG the numerous tributes paid to the genius and labours of Sir Charles Wheatstone, the Italian Scientific Association of the Forty lately forwarded to him, through the British Legation in Florence, its annual gold medal for the greatest discoveries in physical science, a medal founded by its president,

Digitized by Google

Professor Matteucci, and which the society unanimously adjudged to Sir Charles in acknowledgmen of his celebrated and invaluable contributions to the science of electricity.

AT the last meeting of the Society of Engineers, Baldwin Latham, Esq., president, in the chair, twelve candidates for election were balloted for and duly elected. As members:—Messrs. John Rowan, Aylesbury; Hugh McIntosh, Lambeth; William R. Lacey, Wandsworth; Charles Lendey, Royal Small Arms Factory, Enfield; Edward Sacré, Parliament-street; J. Edwin Phillips, Spittlegate Iron Works, Grantham; Christopher Brakell, North Moor Foundry, Oldham. As foreign members: —Lieutenant Constantine Astapoff, Railway Department, St Petersburg. As associates:—Messrs. John C. Mewburn, 166, Fleet-street, and Johnson Vivian Jeffrie, Crossness.

THE village of Carpino, in the Neapolitan province, has been visited by a calamity. A late number of the "Italian" reports that enormous masses of earth and stones, loosened by the melting of the snow, became detached from the mountain, at the foot of which the village stands, and came down like an avalanche, completely burying the parish church, the priest's residence, and two houses adjoining. The inmates, warned of the danger in time, escaped half clad; but, although no lives were lost, these poor people have been reduced to destitution.

THE farmers in Devonshire are complaining of the increase of the ringdove or wood pigeon. These birds visit that country now in large flocks. They feed on beech nuts, acorns, turnip and swede greens, young clovers, cabbage plants, tares, peas, &c. When feeding they have scouts who give notice of danger. They breed often during the year. They commence cooing in March. Many of their early-laid eggs are devoured by jays. They build their nests carelessly, and their young often fall out of them.

ON Thursday week the annual ploughing match of the Bywell Society took place at Nafferton, Northumberland. Upwards of sixty ploughmen competed for the prizes, and as the soil in that neighbourhood is a rich stiff clay, an opportunity was afforded of showing the very highest class of work under the most favourable circumstances. The finest ploughing was of the champion class, in which all the prizes, including a five guinea lever watch, were won with Messrs. Ransome's ploughs. In the boys' class some excellent work was done by the fifteen competitors, considering that they were restricted to the use of 3ft. mould boards, and here again the first prize, a silver watch, was won with one of the same implements.

ON the 16th of October last there was a gale off Labrador, which destroyed 80 vessels, and numerous lives; on the 29th, there was a hurricane at St. Thomas, which destroyed nearly 100 vessels, and nearly 1,000 lives; on the 30th, there was a hurricane at St. Domingo; on the 1st of November, there was one at Hong Kong; on the 2nd, there was one at Calcutta, during which the loss of life and property was very great; on the 3rd, the eruption of Vesuvius commenced; on the 8th, there was a tornado at Matamoras, which did damage to the amount of a million sterling; on the 20th, there was a volcanic eruption in Nicaragua; and on the 20th, there was an earthquake felt at New York, Vermont, and Canada.

MR. GLAISHER reports that the mean temperature of the air in the three winter months ending February, 1867, registered at the Royal Observatory, Greenwich, was 40·6deg., being 1·4 above the average of the preceding 26 years; in the three spring months ending May, 46·7deg., being 0·4 below the average; in the three summer months, ending August, 59·8deg., being 0·8 below the average; in the three autumn months, ending November, 49·2deg., being 1·3 lower than the average; in December, 1867, 37·5deg., being 1·6 lower than the average of 96 years. The highest temperature registered in 1867 in the 56 stations from which Mr. Glaisher has returns was 91·2deg. at Royston, Herts, in August; the lowest was 0·0, at Lampeter, Cardiganshire, and also at Norton-in-Hales, Shropshire, in January, 1867.

A SPEEDY and mighty change in the character of the great Niagara Falls is looked for. It has long been known that beneath the hard limestone shelf over which the vast body of water passes there is a soft stratum of shale. The slow wearing away of the limestone gave a long lease of existence to the falls, but the lease is now threatened with a sudden termination by the certain indications in the currents about 800 yards above the Canadian falls, which, show that the water has got at the sublying shale and is rapidly eating it away. It has even been ascertained that a subterranean stream of water is now pouring into the gulf below the falls, and everything goes to prove that the great limestone shelf known as the "Horseshoe" will soon be completely undermined and destroyed. Two effects are anticipated from this—the conversion of the falls into a rapid thereby rendering the "shooting of Niagara" practicable, and, secondly, the diverting of the entire body of water to the Canadian side, the United States being thus robbed of their share of the mighty cataract by the Britishers.

Patents for Inventions.

ABRIDGED SPECIFICATIONS OF PATENTS.

THE Abridged Specifications of Patents given below are classified, according to the subject to which the respective inventions refer, in the following table. By the system of classification adopted, the numerical and chronological order of the specifications is preserved and combined with all the advantages of a division into classes. It should be understood that these abridgments are prepared exclusively for this Magazine from official copies supplied by the Government, and are, therefore, the property of the Proprietors of this Magazine. Other papers are hereby warned not to produce them without an acknowledgement:—

BOILERS AND FURNACES—1955
BUILDINGS AND BUILDING MATERIALS—1922, 1953, 1990
CHEMISTRY AND PHOTOGRAPHY—1950, 1994
CULTIVATION OF THE SOIL, including agricultural implements and machines—1952, 1991, 1995, 1996, 1997, 2002
ELECTRICAL APPARATUS—None
FIBROUS FABRICS, including machinery for treating fibre, pulp, paper, &c.—1923, 1925, 1932, 1933, 1975, 1998
FOOD AND BEVERAGES, including the apparatus for preparing food for men and animals—None
FURNITURE AND APPAREL, including household utensils, time-keepers, jewellery, musical instruments, &c.—1954, 1957, 1964, 1970
GENERAL MACHINERY—1920, 1921, 1927, 1928, 1935, 1937, 1944, 1946, 1948, 1956, 1968, 1973, 1982, 1992
LIGHTING, HEATING, AND VENTILATING—1931, 1938, 1967, 1986, 2004
METALS, including apparatus for their manufacture—1939, 1980
MISCELLANEOUS—1929, 1930, 1942, 1945, 1947, 1949, 1951, 1960, 1969, 1972, 1977, 1978, 1983, 1985, 1987, 1988, 1989, 2006
ROADS AND VEHICLES, including railway plant and carriages, saddlery, and harness, &c.—1959, 1976, 1979, 1981
SHIPS AND BOATS, including their fittings—1924, 1943, 1958, 1961, 1963, 1993
STEAM ENGINES—1936, 1940, 1941, 1966, 1974, 1984, 1999, 2000, 2001, 2003
WARFARE—1926, 1934, 1962, 1971

1920 J. R. BURN. *Improvements in presses for cutting paper.* Dated July 2, 1867.

One part of this invention has for its object to do away with the necessity of screwing down the pressing bar of paper cutting presses by hand every time before cutting, by causing the machine to effect this automatically. The inventor attaches the pressing bar to a screw spindle which passes through a tapped boss on a strong lever, the fulcrum of which is supported by the framing, while the end of the lever is connected to a rod which is so actuated by a cam driven by the machine, that the lever, and consequently the pressing bar, is depressed whenever required to nip the paper, and then raised to release the paper. Another part of the invention consists in arranging the gauge against which the paper is set before cutting to turn back on a hinge, so as to allow of the paper being removed from behind the machine after having been cut.—Patent abandoned.

1921 W. DUCK. *Improvements in stoppering bottles, and in the apparatus to be employed therein.* Dated July 2, 1867.

This invention relates to stoppering bottles, whether of glass or metal, or both combined, by means of a glass or porcelain cup or cover, having a female screw therein, which is turned on the male thread on the neck of the bottle to be stoppered.—Patent completed.

1922 W. STEVEN and A. ROBERTSON. *Improvements in brick-making machines.* Dated July 2, 1867.

This invention relates to machines of the kind described in a former patent, dated March 22, 1841 (No. 8897), and one of these improvements consists in dispensing with certain pistons or plungers employed in the machines constructed according to that invention. A cover of metal or wood is placed over each pug mill outlet, and is shaped so as to lead or guide the issuing clay down into the moulds or mould openings in the sliding frame. A second improvement consists in actuating the remaining pistons or plungers by means of weights in combination with levers, which levers have their movements regulated by cams shaped with depressions to allow of the descent of the weights at the proper times, and the inclined sides of which depressions re-elevate them by a positive action. A third improvement consists in introducing a yielding appliance in the driving arrangement, so that when from obstructions in the machine the resistance becomes injuriously increased, the parts will slip, and thereby save the gearing.—Patent abandoned.

1923 J. GREENHALGH. *Improvements in machinery or apparatus for opening and cleaning cotton or other fibrous materials.* Dated July 2, 1867.

This invention relates to machines for opening and cleaning cotton and other fibrous materials known as "willows." The first improvement relates to a new mode of supplying the cotton or other material to the machine. The second consists in apparatus for delivering the cotton or other material (after it is cleaned and opened) from the machine. The third consists in the application of a slide to close the aperture leading to the dust fan.—Patent abandoned.

1924 G. A. F. FOWKE. *Improvements in compositions for preventing the fouling of the bottoms of ships, floating docks, and other similar structures, and in the mode or means of applying the said compositions.* Dated July 2, 1867.

Here the patentee takes the following ingredients, in certain proportions, namely, pitch, resin, plumbago, tallow, and cement. He melts the ingredients. He next prepares a composition of the same ingredients (with the exception of the tallow), and uses it as a second coating over and above the first. He now takes sulphur, plumbago, and cement, in certain proportions, and melts them. He runs this composition into moulds to form plates, rolling it during the process for rendering the plates of sufficient density, and forcing it into the moulds. He makes the edges of these plates bevelled, and coats them with a dressing of both or either of the compositions first described. The composition already spread upon the ship being warmed, and that upon the plates being also warmed, the plates are pressed on to their places on the surface to be coated where they adhere, and the interstices between the plates are filled up at the bevelled edges with the composition last referred to, in a soft state. This he presses in with hot irons, making a perfect joint, and forming one homogeneous surface.—Patent completed.

1925 T. and J. WOOD. *Improvements in machinery for printing hanks of yarns or threads with one or more colours.* Dated July 2, 1867.

The patentee arranges the ribs on the distributing rollers to correspond by means of toothed wheels with certain ribs on the printing rollers for printing one or several colours on hanks of yarns or threads, all as described and illustrated in the drawings.—Patent completed.

1926 A. M. CLARK. *Improvements in breech-loading ordnance.* (A communication.) Dated July 2, 1867.

This invention is not described apart from the drawings —Patent abandoned.

1927 J. STURGEON. *Improvements in machinery employed in getting coal, stone, and other minerals, and in apparatus connected therewith.* Dated July 2, 1867.

The chief object of this invention is to produce a machine capable of performing the principal operations required in tunnelling or making a drift, long wall, cutting or pillar, and stall cutting, or to work at an irregular face of coal of any length. The patentee employs a cutter or cutters actuated by an engine worked by compressed air, which is so arranged that the cutter may have an independent forward motion imparted to it for a certain length without shifting the whole machine bodily from its original situation during the process of cutting.—Patent completed.

1928 A. SCHWARTZ. *Improvements in lubricators for lubricating rotating shafts and other moving surfaces.* Dated July 2, 1867.

Here an oil vessel is employed, which is made of glass, and is of a bottle-like form. Into the mouth of it there is fitted a stopper through which a pipe passes, the interior of which is filled with a group of minute tubes. The inner end of the pipe is covered with a cap, in the centre of which is a small hole. When the apparatus is in use it is inverted and the pipe inserted in a hole bored for it in the bearing, so that it and the small tubes within it rest upon the shaft or surface to be lubricated. In this apparatus the oil does not flow out when it is inverted in consequence of the small diameter of the tubes, and because there is no free admission of air to the upper part of the oil reservoir, but the shaft or moving surface being in contact with the tubes draws the oil from them.—Patent abandoned.

1929 T. YOUNG. *Improvements in buttons or fastenings for dress.* Dated July 2, 1867.

The inventor forms the button in two parts, one of which forms the back and the other the front of the button; the back portion is made like an ordinary suspender or brace button, with three or more holes formed through it, so that it may be attached to a garment by sewing. Through the centre of the back part of the button is another hole in which is cut a screw thread. The front of the button carries at its back a projecting pin or shank with a male screw which can be screwed into the central hole in the back portion of the button which is sewn on to the garment. Thus, when the garment is not being worn, the face of each button upon it may be removed and may be screwed on to other back pieces either loose or sewn on to other garments.—Patent abandoned..

1930 G. GORDON. *Improved means of, and apparatus for, washing and drying moist substances, or drying and burning granular substances, or evaporating liquid substances, and for economizing the waste heat produced in such processes.* Dated July 2, 1867.

The patentee claims the utilization of the waste and unintentionally made steam given off in drying moist and evaporating liquid, solid, or aeriform matters, for saving the heat of such steam. He also claims the washing, drying, or burning of granular substances (as exemplified in the specification in the instance of animal charcoal), and the utilization of the waste steam and heat given off in the processes so described, except so far as the same are repetitions of processes embodied in a patent granted to him in the year 1866 (No. 2571).—Patent completed.

1931 J. SOMERVILLE and R. ELSDON. *Improvements in the treatment of apparatus employed in the manufacture and materials used in the purification of gas.* Dated July 3, 1867.

The patentees claim the use of chalk limestone, or foul gas lime, for removing carbon without injury to the retort, and the obtainment of a useful product thereby, substantially as described.—Patent completed.

1932 J. ELCE and P. WILLIAMS. *Improvements in machinery for spinning and doubling.* Dated July 3, 1867.

The patentees claim, first, the giving a positive traversing motion in either direction, and at any speed, to the endless band supporting or acting on the bobbins of throstle, spinning, and doubling frames, for varying the drag in accordance with the diameter of the bobbin, and the combs of yarn to be spun or doubled; and, secondly, the giving a positive traversing motion to the rod to which the ends of the weighted cords are attached for varying the drag according to the increasing diameter of the bobbin.—Patent completed.

1933 W. R. LAKE. *Improvements in machinery for manufacturing cordage, webbing, and other like articles.* (A communication.) Dated July 3, 1867.

This invention relates to a previous patent, dated May 8, 1866 (No. 1318). To obviate delay and inconvenience, and to reduce the strain on the strands, the inventor employs a hook of peculiar form, around which is loosely fitted a hollow cup or sleeve. The latter is pressed up against its head by a spring, the tension of which is regulated by a screw nut, the strand being conducted from the spool, reel, or bobbin over the edge of the cup down under the hook, and thence up over the opposite edge to the required point. By this construction, when the strand becomes knotted, the edge of the cup against which the strand is drawn is tipped or rocked down to afford room for its entrance between the cup and hook, after which the knot is drawn up between the opposite side of the hook and the edge of the cup, which then yields or rocks downwards, as above described. Second, the invention consists in pivoting to the spindle or latch, which may be adjusted in a line with the spindle, so as to form a continuation of the same, and allow the spool or bobbin to be slipped thereon, and then

Digitized by Google

adjusted into its normal position at right angles, or nearly so, to the spindle, thus securely confining the spool or bobbin in place on the latter.—Patent completed.

1934 F. R. AIKMAN. *Improvements in firearms and ordnance for the purpose of instructing soldiers, volunteers, and others, with a short range only, to fire with precision over long ranges, and for obtaining a correct register of each shot.* Dated July 3, 1867.

The patentee claims the arrangement of an outer sectional cylinder and inner barrel, and mode of adjusting the same, as described, for practising long-range firing over a short range only, the outer or false barrel or sectional cylinder used for sighting only being raised or elevated as required, while the inner barrel is proportionately depressed and kept point blank to the target, which target the bullet will strike if the sighting and aiming of the outer or false barrel or cylinder for the long range be correct. He also claims the application of the principle, as described, to ordnance and heavy guns.—Patent completed.

1935 J. M'KIBBIN. *Improvements in appliances for filling into and drawing liquids from casks and other vessels, and for excluding the air from such vessels when empty.* Dated July 3, 1867.

The patentee claims, first, a ring or bushing arranged with an inner rim or flange, and fastened in the manner and for the purposes described. Second, a plug or bung arranged with a perforation and adjusted to a ring or bushing so as to admit the air at pleasure into a vessel, in the manner and for the purposes described. Third, a plug arranged with perforations, a screw thread, and slots adjusted to a fixed coupling ring or bushing, and moved by a tap arranged with a shoulder or screw thread, and spuds or tongues, in the manner and for the purposes described.—Patent completed.

1936 H. and D. DAVY. *Improvements in centrifugal governors, and means of governing steam and other engines.* Dated July 3, 1867.

The patentee claims, first, the application of a curved horn (or horns) from which the pendulums of centrifugal governors may be suspended, as described. Second, constructing the pendulum arms of steel (by preference), as described. Third, constructing the forked or other arms on or between which the pendulums move of a curved form, as described. Fourth, arranging the pendulums so as to obtain the relative positions described. Fifth, the arrangement of quadrant, lever, and catches applied for operating the spindles of throttle valves, as described.—Patent completed.

1937 W. GALLOWAY and G. PLANT. *Improvements in the manufacture of welded tubes, and in apparatus employed for that purpose, which latter are partly applicable to other purposes.* Dated July 3, 1867.

The patentees claim, first, welding conical or tapering tubes by first placing the skelp upon a tapering mandril of a form corresponding with that of the interior of the tube when finished, and then passing the same through a rolling mill, the rolls of which have grooves of a tapering form, and of a circumferential length equal to or greater than the length of the tube. Second, constructing smiths' fires for heating conical or other tubes with two opposite tuyeres, or two opposite rows of tuyeres, arranged and operating as described. Third, arranging in smiths' fires one or more annular pipes having apertures serving as tuyeres, the annular water spaces of which pipes communicate with one or more strong water chambers or steam boilers arranged and operating as set forth.—Patent completed.

1938 D. P. MORISON. *Improvements in miners' safety lamps.* Dated July 3, 1867.

This invention relates, first, to lamps in which the air necessary for combustion is admitted through perforations above the cylinder surrounding the flame. Second, to lamps in which such air is supplied through perforations below the said cylinder, and the improvements are designed to prevent any communication between the flame of the lamp and the surrounding explosive mixture, even when the latter presses against the lamp at a high velocity. In the first case, the inventor employs a cylinder of sheet brass or other metal in lieu of the metallic gauze generally used. In this chimney he places at short intervals discs of wire gauze. The air is admitted at the top of two cylinders of glass or other material surrounding the top through a ring of wire gauze; or it may be admitted at the bottom of the cylinder and pass upwards. Over the top of the two cylinders a protecting shield is placed. In the second case the air is made to pass under the protecting shield of brass or other metal and a series of perforations, then through a ring of wire gauze and another series of perforations before reaching the flame. In this lamp a cylinder of glass is placed entirely surrounding an interior cylinder of wire gauze, and prevents any current from reaching the interior of the lamp.—Patent completed.

1939 T. BORLASE. *Grinding and pulverizing metallic ores and any other substances.* Dated July 3, 1867.

In the first place the work enters the bell mouth of the cones employed in this machine with water (the latter being conveyed to the feeder by a pipe or launder, and the feeder supplying the water, and also the mineral, &c., used in such quantities as may be required), where it is torn up and reduced to a proper size by ribs and grooves cast in the mouth of the mill to pass through or between the plain surfaces of the cones, which are constructed of cast iron fitted closely together, so as to bruise every grain, where it will be kept by regulating the quantity of water that is left in with the work, and confining the work by the adjusting ring at the outer edge of the mill, which is perforated for the purpose, a sufficient time to be brought into a fit state to pass over a separating machine or machines that may be required. The regulating of the work will be by admitting water in greater or less quantities, and by adjusting the perforated ring till the material is made very fine.—Patent completed.

1940 W. S. SCOTT and W. H. STEEL. *Improvements in self-acting escape or relief valves applied to the cylinders of steam engines.* Dated July 3, 1867.

The object here is to obtain the free escape of the condensed steam, and any water that may be carried over into the cylinders from the boiler. This is effected by the fitting of a pipe from each end of the cylinder to a box containing two valves fixed on the same spindle with corresponding valve seats, so that one valve acts upon the other alternately, whereby as one valve is closed by the steam entering one end of the cylinder from the boiler, the other is opened to allow the escape of the water from the exhaust end of the cylinder.—Patent completed.

1941 R. SHAW. *Improvements in motive power engines.* Dated July 3, 1867.

Within a cylinder provided with a valve to regulate the admission of the steam, &c., the inventor places a piston made longer or deeper than those now in use. This piston reciprocates as in ordinary motive power engines. It is fitted with an eccentric and guide or crank within itself. The eccentric or crank is secured on the main shaft which passes transversely through the cylinder and piston, and by these parts the reciprocating motion of the piston is converted into rotary of the main shaft. Bed plate, framing, bearings, connections, and appurtenances requisite in ordinary motive power engines are provided.—Patent abandoned.

1942 J. H. JOHNSON. *Improvements in the mode of preserving butter and substances of a similar nature.* (A communication.) Dated July 3, 1867.

This invention consists in retaining butter, &c., free from contact with the sides of those vessels in which it is enclosed, and surrounding it with purified or distilled water, or with distilled water containing in solution carbonate or bi-carbonate of soda, or other alkali, such as potash, either alone or in conjunction with tartaric acid, or other acid capable of liberating carbonic acid from such alkaline solutions.—Patent abandoned.

1943 H. CLARKE. *Improvements in propelling vessels.* Dated July 3, 1867.

This invention relates to the propulsion of vessels by a rotary sail, that is to say, by a large surface extended to operate on the atmosphere. The axis of the rotary sail is actuated by steam power in the vessel, and is caused to rotate thereby at a rate suitable for the speed to be obtained. The sail in rotating presents its oblique surfaces to the atmosphere, against which they press, and force the vessel onwards.—Patent completed.

1944 D. DAVY. *Improvements in steam and other hammers whereby to effect economy in the use of the steam or other fluid actuating the said hammers.* Dated July 3, 1867.

The patentee claims, first, passing a portion of the steam, &c., which has raised the hammer to the top side of the hammer piston, and passing a portion of the steam, &c., which has acted on the top side of the hammer piston in the descent of the hammer, to the underside of the said piston, in each case before the steam, &c., is admitted into the cylinder at the initial pressure. Second, the several arrangements of valves.—Patent completed.

1945 W. THOMPSON. *Improvements in mouthpieces for cigars and pipes.* Dated July 3, 1867.

The patentee claims, first, providing mouth pieces for cigars and pipes with a chamber containing cotton wool, or its equivalent, through which the smoke has to pass on its way to the mouth. Second, the employment of a case for containing the cotton or other wool, constructed and operating as described.—Patent abandoned..

1946 J. SALMON and G. W. HICK. *Improvements in machines for ruling paper, part of which improvements is also applicable to guiding paper into printing and other machines.* Dated July 3, 1867.

These improvements consist, first, in arranging the machine so that the paper may be ruled on both sides, although it is passed only once through the machine; and, second, in using self-acting mechanism to raise the pins after the paper has passed from underneath them in order to prevent them from inking the aprons.—Patent abandoned.

1947 F. LEONARDT. *A new or improved combined lamp and match box.* (A communication.) Dated July 3, 1867.

This lamp is made of a cylindrical figure, and is fixed in the axis of a tube of larger diameter, the tube being closed at bottom. The annular space between the lamp and the tube forms a box in which the matches are placed.—Patent abandoned.

1948 J. M'ADAMS. *An improvement in machinery for printing from a chain of types.* Dated July 3, 1867.

This invention is not described apart from the drawings.—Patent completed.

1949 W. E. NEWTON. *Improved apparatus for the manufacture of soda water and other aerated liquids.* (A communication.) Dated July 3, 1867.

Here the pump feed and agitator to the condenser are connected together without the application of joints to the latter above the average level of the water therein. The feed and agitator are operated through the base of the condenser, and the discharge of feed pipe passes from the pump into the condenser, and imparts to it a reciprocating action by or with the pump, so that the pressure of gas or liquid in the condenser is made to assist the pump in its discharging or feeding stroke to the condenser by acting upon the exposed end of the discharge pipe or devices connected therewith. In combination with the condenser there is a pump for charging and keeping up the supply to the latter. The constituent parts of this pump are a stationary hollow plunger, and a reciprocating cylinder, with inlet and delivery valves, and an upper reciprocating discharge or feed pipe. The invention further consists in arranging on the end of the discharge pipe which projects into the condenser from below one or other equivalents constructed so as (in the reciprocating action of the pump) to catch and distribute the gas in the water, and to agitate the latter within the condenser, for effecting a thorough mixing of the gas and water.—Patent completed.

1950 A. E. HERRMANN. *An improved lubricating compound.* (A communication.) Dated July 3, 1867.

This invention consists in the production of a lubricating compound formed from lime soap (composed of lime, firm grease, and fine oils) dissoved in fine oils and paraffin oil.—Patent abandoned.

1951 E. M. BROWN. *Improvements in apparatus for carrying umbrellas.* Dated July 3, 1867.

This apparatus consists of an ornamental plate with a chain attached to it. The plate is secured by a band to the waist of the wearer, and the chain has a ring at its lower end through which the lower extremity of the umbrella stick is inserted. To secure the upper end of the umbrella, it is encircled by another short chain, also fixed to the plate, and having a cross bar at its end, which is, to make it fast, passed through another ring near the upper end of the first chain.—Patent completed.

1952 R. HELLARD. *Improvements in reaping and mowing machines.* Dated July 4, 1867.

This invention comprises, first, a drop stay kept down by a spring on the turned or grooved part of the spindle of the bevel wheel by the inside bearing to keep it from springing out of gear in which works the knives. Second, a tilting (table) side delivery platform to swing in its centre, or nearly so, and to be self-acting, or to be worked with the hand or foot. Third, a side delivery platform hung with hinges or hooks and twists or joints to that part or side of the machine against the standing or uncut crop. Fourth, the vane reel formed of iron or steel, thus making the reel vane, shaft ends, and vane reel of metal. Fifth, a lever bolt with and without spring with a claw at the end for throwing the revolving canvas or other revolving platform and octagon or other rollers behind the knives in and out of gear, and which claw bolt is fixed behind the driving wheel on the back part of the frame in a horizontal line pointing towards the end of the aforesaid roller or rollers. Sixth, a revolving roller or rollers between the knife bar and the revolving platform in order to raise the corn, &c., when cutting on to the side delivery, tilting, and other platform. Seventh, the creepers for getting up the down-laid crops, previously patented by the inventor the 11th March, 1859 (No. 626), which are to be made of steel or cast or malleable iron.—Patent abandoned.

1953 T. WELTON. *A new revolving shutter or blind, to be applied either inside or outside of houses or other buildings.* Dated July 4, 1867.

This invention consists in making a shutter or blind of sheet iron or steel, so that each part (described as plates) interlocks with the other and others, and so forms a continuous hinge or hinges, to the front of which may be affixed laths of wood, or metallic bars of the required thickness of any sectional form or width, either as regards the plates, otherwise hinges, or the outside covering (if any) of iron or wood.—Patent abandoned.

1954 J. FERREYT. *A new system of organs, with two, three or four keyboards and separate pedals.* Dated July 4, 1867.

This system of manufacturing organs allows the organist to transpose altogether, or in part, the action on the rows of pipes of which the organ is composed from the first keyboard to the second, and vice versa, as well as to the pedals.—Patent completed.

1955 T. and T. VICARS, and J. SMITH. *Improvements in self-feeding smokeless furnaces.* Dated July 4, 1867.

This invention relates to that class of self-feeding smokeless furnaces, such as Incke's, and Wilson and Smith's, wherein a progressive movement is given to the fuel, and consists, first, of an improvement on that furnace fire-grate for which Messrs. Wilson and Smith obtained a patent, dated September, 1863 (No. 2206). Between the bars described in the specification of that invention the present patentees place other firebars; these latter are moved backwards and forwards a shorter distance than the travel of the former, from which they receive motion, studs and slots being employed for that purpose. Second, of means for supplying fuel to all furnaces in which a progressive movement is given to the fuel resting on the fire-grate. Instead of passing all the fuel from the front through or under the door of the furnace, they supply part or the whole from the top at a greater or lesser distance from the front or back, according to the size of the fire-grate. They place a hopper over or higher than the top of the fire-grate, and lead tubes or enclosed ways therefrom; these terminate directly over the fire-grate. For steam boiler furnaces they carry the tubes or ways through the boiler; screws, &c., are worked on the tubes or ways to propel, measure, and regulate the feed of fuel.—Patent completed.

1956 P. F. TRANCHAT. *Certain improvements in machinery for cutting fraises.* Dated July 4, 1867.

The patentee mounts the circular cutter to be cut on a spindle capable of turning on its axis, and provided with a gauged plate for dividing its circle of rotation in any given number of parts, and over this stationary cutter to be cut, and transversely with its spindle, he places a lever suspended by an universal adjustable joint at one of its extremities, and containing at a short distance therefrom a small working circular cutter adjusted on centres, and rotated over the cutter to be cut; at a distance about five times that of the working cutter from the extremity of the lever he places an adjustable guide plate, on which the lever rests, and which plate is an enlarged representation of the profile of the cutter to be cut; by traversing the said lever over this guide plate, the working cutter is traversed over the stationary cutter, on which one tooth or cut is then made; the stationary cutter is then rotated the required amount for another tooth, and these two successive operations are repeated until the entire circumference of the stationary cutter has been cut.—Patent completed.

1957 A. A. CHAMPION. *Improvements in chronographs or apparatus combined with chronometers and other timekeepers for measuring and indicating short intervals of time.* Dated July 4, 1867.

This invention has for its object the arrangement of mechanism in combination with a chronometer or other timekeeper to act as a "chronograph" instrument for measuring and recording short intervals of time without interfering in any way with the timekeeping quality of the chronometer or timekeeper with which such mechanism or apparatus is combined, and comprises numerous intricate mechanical arrangements which we cannot give space to here.—Patent abandoned.

1958 H. CLARKE. *Improvements in apparatus for propelling vessels.* Dated July 4, 1867.

This invention relates to apparatus for propelling by its action in the atmosphere. The patentee provides what he terms a rotating sail (or sails), being oblique vanes or sections of screws mounted on a horizontal axis; such vanes he constructs of a series of radial arms extending from the axis, so that canvas, &c., when stretched thereon, will present a surface which, when the axis is rotated, will act in the manner of a screw on the air, and so produce an end thrust on the shaft, and, consequently, propel the vessel.—Patent completed.

1959 F. BRADY. *Improvements in apparatus for working railway switches and signals.* Dated July 4, 1867.

Here, when a switch lever is moved to shift a switch, all the signals which must then necessarily be set at danger will be locked in that position. The patentee claims connecting the switch levers with spindles or axes having locking axis upon them acting upon the signal levers or links, or parts connected therewith, as described.—Patent completed.

1960 J. BOLTON. *Improvements in stands or holders for croquet balls and implements.* Dated July 4, 1867.

The stands or holders have a tray, box, or base, and a cover with locks and bolts, and locked flaps, lids, or sides arranged and combined together.—Patent completed.

1961 W. DAY. *Improvements in the mode of applying metal sheathing to iron ships, caissons, and floating docks, and*

Digitized by Google

other iron constructions subject to corrosion. Dated July 4, 1867.

The patentee claims the mode described of putting zinc or other electro-positive metal in strips with screws or rivets of iron, zinc, or other suitable metal, upon iron ships' caissons, floating docks, &c., thereby preventing corrosion. —Patent completed.

1962 W. E. NEWTON. *Improvements in breech-loading fire-arms.* (A communication.) Dated July 4, 1867.

This invention consists in the use of a lever and a sliding extractor so combined with a chambered breech-block hinged at one side that the said lever not only serves as a thumb-piece, whereby the breech-block may be turned laterally from the breech receiver to unclose the breech, but may also be used to operate the extractor to expel the empty cartridge shells from the barrel. The invention further consists in an arrangement of such lever with reference to a notch or recess formed in the rear end of the breech receiver, whereby the lever may also be employed to securely lock the breech-block in position to close the breech.—Patent completed.

1963 A. V. NEWTON. *An improved combined ship's propeller and steerer.* (A communication.) Dated July 4, 1867.

This propeller consists of a vertical shaft supported in bearings at a suitable depth in the water. From this shaft proceed two or more tiers of radial arms arranged with their edges horizontal, so as to afford little resistance to the water. The lower arms are made somewhat shorter than the upper, so as to give the complete outline of the propeller the shape of an inverted truncated cone. To the extremities of these arms are hinged rectangular or rhomboidal blades or paddles, the hinges or pivots being placed on their vertical central line. A tubular or sleeve shaft surrounds the upper portion of the main shaft, and is free to turn upon it. This sleeve shaft is connected by gearing with the tiller. In order to enable the blades or paddles to feather as the wheel rotates, there is fitted to the foot of the sleeve shaft an eccentric around which is a strap free to revolve, and to this strap are attached radial eccentric rods or arms having their other extremities pivoted to the steel blades or paddles out of the central line thereof. The upper end of the main shaft (above the sleeve shaft) connects by a crank, &c., with the source of power.—Patent completed.

1964 I. PICK. *Improvements in scarfs and other like articles of wearing apparel.* Dated July 4, 1867.

The inventor manufactures a scarf, or like article, so that it shall also serve as a chest protector. He combines with a piece of material, serving as a covering or protector for the chest, a strap or band which passes round the neck of the wearer, or under the collar, being retained in place by hook, button, or otherwise.—Patent abandoned.

1965 M. HENRY. *Improvements in apparatus for raising and lowering heavy bodies.* (A communication.) Dated July 4, 1876.

The platform, carriage, cradle, or weight to be raised or lowered, travels on an inclined way or inclined side, or portion of the framework. The framework may be constructed in vertical section of the shape of a right angled triangle, whereof the hypothenuse forms the aforesaid inclined way or side. T-iron, or double T-iron, or angle iron, may be used in the construction of the apparatus or its framework. A base plate or sole, which rests on the ground or floor when the apparatus is at work, is raised therefrom when it is to be moved. For this purpose the base plate or sole is attached to eccentric discs or plates in which the ends of the axle of the wheels are mounted eccentrically, and which turn in plates or pieces forming portions of the framework, so that by raising the axle, the base plate or sole will be lifted off the ground by the eccentrics, discs, or plates which are held in position by catches or stops. The arms or supports of the load to be raised may be used as handles or shafts for draft purposes in moving the apparatus. The weight is lifted by a crank handle actuating a worm wheel which drives a grooved pulley combined with a toothed pinion which engages a lifting chain attached to the load.—Patent abandoned.

1966 H. RUDDICK. *Improvements in steam engines.* Dated July 4, 1867.

This invention relates to a new arrangement of the piston, connecting rod, and crank shaft with relation to each other and the cylinder, whereby the power is brought near the work, and the machine made more compact, lighter, and cheaper, and consists in arranging within a cylinder furnished with the usual induction and exhaust valves two single acting pistons, one at each end, and joining them by lateral rods within the cylinder, so that they shall be held apart at a proper distance compared with the length of the cylinder, to allow of the desired stroke. Intermediate between these two pistons the patentee places a crank shaft across the cylinder, and connects the crank pin on this shaft by a connecting rod with one of the piston heads.—Patent completed.

1967 W. R. LAKE. *Improvements in the manufacture of illuminating gas, and in apparatus employed in the said manufacture.* (A communication.) Dated July 4, 1867.

This invention consists, chiefly, in preventing the formation of carbon in the retorts by relieving them from the pressure caused by the scaling of the mouths of the tubes in the hydraulic main.—Patent completed.

1968 E. O. GREENING and J. ATKINSON. *Improvements applicable to washing, wringing, and mangling machines.* Dated July 5, 1867.

The patentee claims, first, the use of a worm and worm wheel for actuating the rollers of washing, wringing, and mangling machines, as described. Second, the use of compound springs formed of metallic washers and rings made of vulcanized india-rubber, for producing the necessary pressure between the rollers of washing, wringing, and mangling machines, as described.—Patent completed.

1969 P. L. F. E. ROUSSEL. *A finger stall intended for writing with a single finger.* Dated July 5, 1867.

This finger stall has at its upper end an appendage slightly inclined to the right, and forming a holder for a pen, and its other end passes over the index or other finger like a sewing thimble.—Patent abandoned.

1970 C. D. ABEL. *An improved elastic strap for garments.* (A communication.) Dated July 5, 1867.

This invention consists in attaching a buckle to each end of a strip of elastic material, by preference a solid piece of vulcanized india-rubber. This contrivance is applied to the strap of the garment by cutting off the buckle, button, hook, or other contrivance attached thereto, and passing the one end of the strap through the one buckle of the elastic strap, and the other end of the strap through the other buckle thereof.—Patent abandoned.

1971 J. M'NAUGHTON. *Improvements in breech-loading firearms, and in cartridges and projectiles, a part of which improvements is also applicable for converting muzzle-loading firearms into breech-loading firearms.* Dated July 5, 1867.

This invention is not described apart from the drawings. —Patent completed.

1972 H. C. CARVER. *Improvements in hoop-iron fastenings for bales.* (A communication.) Dated July 5, 1867.

This invention consists in cutting the hoop iron to the length required to pass round the bale, in doubling up each end, securing one doubled end by a rivet, making a hole and short slot in it, and in riveting a button or stud in the other doubled end which will fit the said hole and slot.—Patent completed.

1973 W. R. LAKE. *Improvements in machinery for manufacturing metal tubes.* (A communication.) Dated July 5, 1867.

This invention relates to mechanism for forming sheet metal tubes or pipes with a lap joint, the object being to so construct and arrange the parts that the successive operations are performed automatically. The material in the form of a plate or long flat strip is fed into the machine at one end, and is thence passed on by a series of feed guide and bending rolls which gradually bend the plate around a stationary cylindrical mandril, so as to bring the opposite edges together, lapping one edge over the other, and bending the edges thus joined down to the cylindrical surface of the mandril, the sheet or strip being finally delivered from the opposite end of the machine in the form of a finished tube.—Patent completed.

1974 W. C. CHURCH. *Improvements in, or applicable to, steam and other motive engines.* Dated July 6, 1867.

First, these improvements relate to the slide valves of engines, and to arrangements for removing the excess of pressure from the back of the valve. The back of the valve is modified in shape, so as to receive a circular cap or ring; the upper side or edge of this cap or ring is made to work against a fixed plate which forms a part of the top or cover of the valve chest, when there is only one valve, but when two valves are arranged back to back the plate is placed between them and acts for both valves. The cap or rings is pressed against the said fixed plate partly or wholly by the steam or other motive power used, and partly by springs abutting against the top of the slide valve and acting against the under side of the cap or ring. The joint or space between the slide valve and its cap or ring is made steam-tight by metallic ring packing, which is pressed upwards against a junk ring secured upon the top of the valve, and outwards circumferentially against the inside of the cap or ring. Thus arranged the cap or ring will move with the valve, and will be pressed at the same time so as to be steam-tight against the said fixed plate, and thus the pressure of the steam or fluid in the valve chest will be prevented from acting upon that part of the back of the valve enclosed by the ring or cap. The fixed plate has a passage formed in it which communicates with the space above the ring or cap, and with the atmosphere, so that if there is any leakage, this can be readily ascertained. A tap may be placed at the outlet of the passage from the fixed plate so that the outlet may be closed if the leakage is excessive until it can be attended to. Second, the improvements relate to the pistons of steam and other motive engines, and consist in arrangements by which the greatest pressure of steam, &c., may be made to act constantly and uniformly, or nearly so, to press out the packing ring or rings.—Patent completed.

1975 F. ANDREW and L. CLARKSON. *Improvements in machinery used for printing woven fabrics, warps, yarns, and paper.* Dated July 6, 1867.

This invention consists in the employment of a bowl covered with vulcanized india-rubber, &c., instead of the lapping and blanket hitherto employed in printing machines, and cleaning the surface of the bowl with a doctor or roller, either with or without water. The material passes between the printing roller or rollers and the bowl, and the impressions are obtained in a very effectual manner.—Patent abandoned.

1976 W. R. GORST. *Improvements in the construction of wheeled vehicles.* Dated July 6, 1867.

This invention consists in so constructing the bodies of wheeled vehicles that the seat space can be doubled by folding or moving forwards or backwards a movable piece called the minor body placed opposite the ordinary seat or seats. This minor body is fitted on a hinge or joint near the floor of the vehicle, is formed with a rigid frame, is provided with seats on its inner surface, and is made sufficiently roomy to serve as an apron or leg protector when only the ordinary seats are required.—Patent completed.

1977 R. TIERNAN. *An improved tobacco pipe.* Dated July 6, 1867.

The principal objects of this invention are:—First, to prevent the essential oil from entering the mouth of the smoker; and, second, to cause the tobacco to burn evenly and economically. The inventor forms the pipe with a passage at the side of the bowl. One end of the passage opens to the bowl at or near the bottom thereof, and the other to the stem at or near the top of such bowl.—Patent abandoned.

1978 T. C. THOMAS. *Improvements in water-closet fittings.* Dated July 6, 1867.

This invention consists in so arranging the fittings that a regulated quantity of water may be discharged for flushing the basin every time the closet is used. This is effected by establishing at some convenient point above the level of the pan a small cistern or chamber with a tumbling trough which is always kept charged with the regulated quantity of water, and is filled from a reservoir above. The tumbling trough is filled from the supply pipe through a ball-cock which only admits a certain quantity; it is mounted on centre pins, so that when required it may be tipped over, in order to discharge the water. It is worked by gearing consisting of bands and pulleys connected to a lever, which may be actuated by a handle in the ordinary manner; or it may be connected to the door of the closet, so that it may be actuated whenever the door is open. The pan is provided with a syphon, and when the lever is pulled up or the door opened the tumbling trough will be pulled over on its axis, and the water will be discharged therefrom and allowed to rush down the exit pipe with considerable force into the pan.—Patent abandoned.

1979 W. E. NEWTON. *A novel system of constructing railways and working trains thereon, in order to enable trains to ascend inclines of steep gradient.* (A communication.) Dated July 6, 1867.

Here motion is communicated from the engine by means of pulleys and bands to all the wheels of a train, which are thereby driven at uniform speed. The driving wheels are all made to bear on a single rail placed in the centre of the road. When the gradient to be ascended is very steep, the wheels should be set at an angle of about 30deg., so that considerable pressure may be exerted, and a more complete adherence caused than if the wheels were placed vertically on the rails.—Patent abandoned.

1980 T. MORGAN. *Improvements in the construction of apparatus and furnaces for puddling iron.* Dated July 6, 1867.

This apparatus for puddling is as follows:—A "rabbel" is fixed upon a column, such column having a bevel wheel at the top thereof, fitting into another bevel wheel which is fixed upon a fly-wheel connected with a crank shaft. The column works through a dome fixed upon the top of the furnace, there being on the top of the column a flange fitting upon the part of the dome on which the column rests, and upon which it is suspended when the rabbel is employed in puddling. The rabbel has a circular motion, and is provided with three projections thereon to dip into and agitate the molten iron. When the rabbel is not required for puddling, or when it has become too hot to perform its work with safety, it is lifted through an opening in the top of the puddling furnace by means of a rack and pinion. When the rabbel has been thus lifted out of the furnace, it can be cooled by dipping it in a cistern, which may be prepared for that purpose. The opening through which the rabbel is admitted to the furnace is closed by a slide both when the rabbel is in the furnace and when it is not in use.—Patent abandoned.

1981 H. B. WOODCOCK. *An improvement in the manufacture of tyres for railway wheels.* Dated July 6, 1867.

This invention consists in the use of converted or cemented bars for the manufacture of railway wheel tyres, whereby the inventor obtains any required degree of hardness suitable for tyres without destroying their malleability.—Patent abandoned.

1982 T. CRADDOCK. *Enabling persons to fly in the air, either alone as the bird flies, or singly, or in parties, in a car or basket.* Dated July 6, 1867.

We cannot here give space to the voluminous details of this invention.—Patent abandoned.

1983 W. HARRIS. *A process of uniting and compressing sawdust, and other small particles of wood, for the purpose of converting the same into charcoal, and utilizing the naphtha, tar, and other residuary products of such conversion.* Dated July 6, 1867.

This invention consists in converting sawdust, shavings, chips, or other small refuse particles of wood, into solid pieces or blocks by mixing the same with certain of the residue extracted from wood during the process of charring in retorts, and afterwards compressing the same in moulds, the said residue causing the particles of wood to unite or adhere to each other. The pieces or blocks thus formed are intended to be subsequently converted into charcoal in retorts.—Patent abandoned.

1984 W. ARCHER. *Improvements in rotary engines and rotary pumps.* Dated July 6, 1867.

The inventor makes the steam chamber of a rotary engine (in which the steam is made to give motion to the piston) of a circular or ring-like figure, that is, of a figure such as would be produced by taking a tube open at both ends and bending it into a circular form, and joining its two ends. This chamber is situated horizontally, and in its centre is a vertical shaft to which rotary motion is to be given. In the steam chamber is a piston capable of travelling round the steam chamber, and the said piston communicates with the shaft described by means of an arm fixed on the shaft, and connected to the piston through a slot or opening in the upper or inner side of the steam chamber. This slot or opening is covered by means of an annular cover which fits thereon, and which is carried round by the motion of the piston. The chamber has a plate or valve which crosses it, and which is capable of being temporarily withdrawn to permit of the passage of the piston. On one side of the plate or valve is an opening at which the steam enters, and on the other side is the exhaust pipe at which the waste steam passes out. When steam is admitted between the plate or valve and piston, the latter is carried forward by the pressure of the steam, and traverses the circular chamber, carrying the cover and arm with it, and giving rotary motion to the shaft on which the arm is fixed. After the piston has travelled along nearly the whole length of the chamber, and has arrived at the other side of the plate or valve, steam is shut off, and the plate or valve is withdrawn to allow the piston to pass it. On the piston passing the exhaust pipe, the steam which has urged it forward escapes by the exhaust pipe. On the piston passing the plate or valve the latter is made again to cross the steam chamber, and steam being again admitted between the plate or valve and the piston the latter is again urged forward. The steam may be worked expansively or cut off when the piston has performed only part of its stroke. The steam chamber is enclosed in a steam-tight box into which steam is admitted from the boiler. The pressure of this steam on the cover of the slot balances that in the chamber, and there is no tendency in the said cover to rise from the slot.—Patent abandoned.

1985 C. TOFT. *Improvements in liquor frames, and other frames for holding bottles and vessels.* Dated July 6, 1867.

The object here is the securing of the bottles in the frame when not in use, and preventing access to the contents thereof. The inventor makes in the base or foot of the frame a series of circular depressions in which the bottoms of the liquor bottles fit; he uses a movable handle, and so constructs it that it serves both to lift the frame by and to secure the liquor bottles in the frame. He makes the handle of three or more radial arms having expanded terminations, the arms springing from the central rod of the handle. The arms are of such a diameter that their expanded free ends are capable of being brought over and pressed upon the stoppers of the liquor bottles in the frame, or being removed therefrom by giving the handle motion in a horizontal plane.—Patent abandoned.

1986 J. C. MAJOR. *Improvements in furnaces for the production of heat by burning tar, petroleum, and other liquid combustibles, and in the mode of conducting the burning of the said combustibles.* Dated July 6, 1867.

In carrying the first part of this invention into effect the patentee arranges in front of the furnace, at, or somewhat in advance of the place where the furnace door is ordi-

Digitized by Google

narily situated, a vertical opening in which a series of horizontal plates is fixed, the said plates being more or less inclined from the outside of the furnace downwards towards the inside, so that any liquid poured on the plates at the outer sides will run towards the other sides. The plates may be perforated with a series of small holes, so that liquid may flow or drop through from one plate to that next below it. In this case he arranges the openings in one plate so that they shall not be immediately over those in the plate next below it. The air for the support of combustion enters over and under the said plates, or through the openings, where there are any. In order the more effectually to retain the liquid on the plates, sand or ashes may be strewed or fixed on the plates. The tar or petroleum, &c., is supplied from a reservoir on to one or more of the plates where it is ignited. The burning combustible falls from the plate on which it is delivered to a lower plate, and the whole of the plates speedily become so heated as rapidly to volatilize, and promote the burning of the combustible. The vapour of the inflammable liquid on rising from the heated plates becomes mixed with the air passing over, or under, or through the openings in the plates, and burns with the evolution of great heat and light. In carrying the second part of the invention into effect, he adds a small quantity of water to the tar or petroleum, &c.—Patent completed.

1987 N. THOMPSON. *Improvements in unions or apparatus for connecting together pipes or tubes, and for stopping the ends thereof.* Dated July 6, 1867.

This invention relates to a former patent, dated June 8, 1867 (No. 1694), and consists, firstly, in the use of a ring or collar fixed in the middle of the centre sleeve or tube of the union to act as a stop to the packing, but so as to allow of the free passage of the tubes through such ring. The invention consists, secondly, in the application of a packing composed of a ring or tube of soft metal, the inner surface of which fits the tubes or pipes to be connected together, whilst the outer surface thereof, at one or both ends, is of a conical form, and, in order to compress such packing around the tubes or pipes, he employs rings or tubes which are conical on their inner surfaces, and which are connected to, or acted upon, by a screwed sleeve or tube.—Patent abandoned.

1988 G. SEVERN. *Improvements in refrigerators for cooling worts and other liquids.* Dated July 6, 1867.

Within a vat or tank the inventor arranges tiers of pipes with sufficient space between the tiers and between the ends thereof and the tank for a man to pass for cleaning the vat and pipes when required. The pipes of each tier are connected by return bends formed with openings closed by stoppers opposite each line of horizontal pipe for cleaning them out by introducing a brush or otherwise. The tiers of pipes which come against the ends or sides of the vat or tank he prefers to form with angular surfaces, or semicircular, so that they may be flat against the surface of the vat to facilitate cleaning. The hot wort or liquid to be cooled flows in at the upper part of the vat containing the series of tiers of pipes, and is drawn off at or near the bottom. One or more thermometers may be fixed to the side of the vat, the bulbs passing through into the liquor to indicate the temperature thereof. Into the lower part of each of the series of tiers of pipes a jet or jets of water is or are forced, currents of air being also forced in at or near the same point in order to distribute the water in the form of spray through the series of tiers of pipes, so as to absorb the heat from the hot liquor and conduct it away.—Patent abandoned.

1989 J. WHITFORD. *An improved ice-making apparatus.* Dated July 8, 1867.

Here the inventor constructs an apparatus with one vessel within another, the outer one of a cylindrical or other form, so that motion can be given thereto by rolling it to and fro on a smooth surface. The inner vessel is employed to contain the water to be frozen, and the space between the two vessels to contain the freezing mixtures, or vice versa. By preference he fits lids to the apparatus at both ends, the one opening to the freezing mixture, and the other to the ice.—Patent abandoned.

1990 J. CAPPER. *Improvements in the construction of chimney tops.* Dated July 8, 1867.

According to one modification of this invention the inventor makes that part of a chimney top which is attached to the upper termination of the chimney of a cylindrical form, and surrounding the higher part of it by another cylinder of larger diameter, so that an annular space is left between the two. Both of these cylinders are open at the top; the larger and outer one rises above the termination of the smaller one. A short distance below the larger cylinder, and attached to the smaller one, there is a projecting ring from which pieces rise and are attached to the outer cylinder, so as to leave alternately closed and open spaces. Wind enters at the latter, rises upwards in the annular space, and assists egress of the smoke.—Patent abandoned.

1991 J. G. TONGUE. *Improvements in the mode of training hop and grape vines, and other climbing plants.* (A communication.) Dated July 8, 1867.

The nature of this invention consists, first, in a contrivance for supporting the cords around which the vines twine and climb to the top of the trellis, and for keeping each string or cord in its place, and in training the vines in a horizontal or other direction after they have reached the top. Second, in the manner of constructing and arranging the yoke or wicket to which the cords are secured immediately over the root of the vine, so as to present the least obstacle to the necessary culture of the vine during growth.—Patent abandoned.

1992 I. M. MCGEORGE and A. PAUL. *A new or improved plug cock.* Dated July 8, 1867.

The shell or body of this plug valve resembles that of an ordinary straight or throughway stop-cock, with the exception of the opening, which is generally called the "mouth of the shell;" this mouth, instead of being supplied with a gland and stuffing box, or being entirely filled with the plug, is supplied with a lid or cover containing a stuffing box, through which stuffing box a spindle (called a valve spindle) passes, having a screw upon it by which the plug or valve is opened or shut. The lid may be screwed, bolted, or otherwise fastened to the shell.—Patent completed.

1993 J. JOHNSON, E. SHINN, and G. RAGG. *Improvements in signalling apparatus for general purposes, but which is more particularly applicable for use on board navigable vessels.* Dated July 8, 1867.

We cannot here quote the details of this invention. It will probably be noticed in a future number of this journal. —Patent completed.

1994 DR. J. M. LORRE. *Preparing canvas, linen, and cotton for enlarging and printing purposes by photography.* Dated July 8, 1867.

The inventor prepares linen, cotton, silk, &c., by giving it, first, a solution of two ounces of gelatine dissolved in ten ounces of water; he then treats it in the manner hereinafter described with reference to the canvas. He takes canvas prepared in the ordinary way for photographic purposes, that is by using oxide of zinc or lead, and he uses instruments formed of ivory or wood for spreading the coating upon the canvas. He then adds one and a-half ounces of virgin wax dissolved in essence of lavender to one pint of turpentine. The canvas is prepared with three coatings, and dried spontaneously, and when dry he dissolves sixty grains of iodine of zinc in two pints of distilled water, and with half a potatoe and very finely pounded pumice stone rubs this solution on the canvas and dries it with a soft flannel till the surface becomes brilliant. In carrying this invention into effect he further uses three special solutions, the first for printing out or developing the object on canvas by sunlight; the second, for enlarging by artificial light; and the third for printing by contact in a pressure frame.—Patent abandoned.

1995 J. SHANKS. *Improvements in lawn mowing machines.* Dated July 8, 1867.

This invention consists in constructing the sole plates or bottom blades for lawn mowing machines reversible, that is to say, the sole plates or bottom blades are made with two edges, so that when one edge is worn the plate can be unscrewed and reversed, or turned round, when the new edge will be brought into contact with the cutter.—Patent abandoned.

1996 W. TASKER. *Improvements in thrashing machines.* Dated July 8, 1867.

This invention consists, first, in constructing the straw shakers for thrashing machines of a number of strips of wood or iron, which may be fitted with pins or pegs projecting on one or both sides thereof, such strips being attached to leather or other bands working round pulleys, and receiving motion either from a pulley on the drum shaft, or any other convenient actuating medium. Inside this continuous revolving rake, or elevator, is a board which may be ribbed or corrugated on its upper surface, and which may also be perforated; the pins on the inside of the revolving strips in their transit pass up those corrugations in the boards, and carry with them any short straws or cavings that may have passed between the strips, allowing the corn to run down the board, or through it if it is perforated. The pegs on the outside of the strips elevate the straw from the drum on their return round on the underside of the above board, and when empty pass through slots cut in a board or plate, fixed or movable, placed immediately in front of the drum. Second, in constructing and applying to the rocking bars of straw shakers in thrashing machines a flexible hanging bar to carry the same, in place of the fixed bearing at present employed for that purpose. Third, in strengthening the flexible hanging bars used for carrying the caving boards and other parts of thrashing machines by placing at each side, and at the top thereof, one or more strips of any length, or of any convenient material or thickness.—Patent abandoned.

1997 A. MATHER. *Improved machinery for cleaning grain.* Dated July 8, 1867.

This invention is not described apart from the drawings. Patent completed.

1998 A. TURNER and W. HEMSLEY. *An improved manufacture of elastic woven fabric, applicable to the manufacture of gloves, drawers, and other elastic articles.* Dated July 8, 1867.

The object of this invention is to impart elasticity to the articles manufactured, and the invention consists in weaving the fabric diagonally, that is, causing the weft to pass through the shed and across the warp in a diagonal direction, at about an angle of 45deg.—Patent abandoned.

1999 N. CLAYTON and J. SHUTTLEWORTH. *Improvements in traction engines or road locomotives.* Dated July 8, 1867.

Here, in order to obviate the necessity of gearing together the two carrying and driving wheels on the opposite sides of a traction engine with differential or compensating gear, but to allow, nevertheless, the traction engine to be steered with facility, the driving wheels are actuated separately, each by its own steam cylinder and gear.—Patent abandoned.

2000 M. P. W. BOULTON. *Improvements in engines worked by the combustion of inflammable aeriform fluids, and in apparatus for producing such fluids.* Dated July 8, 1867.

In this apparatus the ignition of an explosive aeriform mixture is used to propel a piston, and thereby compress air or fluid in a chamber, which compressed fluid is employed to produce motive power, and the heated products of combustion are applied to a boiler for the generation of steam, which may be used in the same engine as the compressed fluid. Or the products of combustion may be employed to give out heat for other purposes. The invention relates to a previous patent, dated March 10, 1866 (No. 738).—Patent completed.

2001 N. CLAYTON and J. SHUTTLEWORTH. *Improvements in slide valves suitable for steam engines.* Dated July 8, 1867.

In order to enable the steam to be more conveniently worked expansively by a valve governed by a single eccentric, the parts are formed and arranged in the following manner:—The valve face has in it five parts or openings; the central one is in communication with the outlet passage by which the steam passes to the chimney or condenser, as the case may be. The two ports, which are one on either side of the central port or opening, are in connection with passages leading to the ends of the steam cylinder, and over these three ports a U-valve works, but in such manner as never to uncover either of the ports to the steam. The two remaining ports or openings in the valve face are also in connection with the passages leading to the ends of the steam cylinder. These ports serve only for the admission of the steam to the cylinder; over them a flat valve works which receives its motion directly from the eccentric, so as to uncover one or other of the steam ports as the valve makes the last part of its movement in either direction. In the middle of the flat valve is an opening into which the U-valve is received. The U-valve receive its motion from the outer or flat valve, but this is able to slide for a distance independently of it, so that the U-valve only receives motion as the outer or flat valve approaches the ends of its course. From this arrangement it results that the first action of the compound valve as it commences its movement in either direction is to cut off the steam from entering the cylinder, whilst the exhaust steam from the other end is free to escape, the U-valve remaining stationary until the outer or flat valve pushes it over, so as to reverse its position, and then the flat valve admits steam on the other side of the piston.—Patent completed.

2002 W. ANDREWS. *Improvements in hay-making machines.* Dated July 8, 1867.

The patentee claims, first, the constructing hay making machines so that the rakes may be driven at different speeds in the direction known as back action, as described. Second, the constructing hay making machines with the whole of the gearing in the centre of the machine, whilst the rake head is divided into two parts, as described. Lastly, the mounting the rake head in the spring casting in such manner that it can be turned therein, as described. —Patent completed.

2003 J. M'F. GRAY. *Improvements in marine steam engines.* Dated July 9, 1867.

This invention relates to single-acting screw propeller engines, and consists in the employment of a fly-wheel on a friction centre as means for insuring that such engines work smoothly at an uniform speed. The fly-wheel and friction centre are supported or hung on the crank shaft of the engine, on an intermediate shaft, or on the propeller shaft itself; the friction centre is constructed in any ordinary manner.—Patent abandoned.

2004 J. J. BUCKLEY and C. HOOK. *The manufacture of a gas of superior illuminating and heating powers, together with the necessary appliances for the same being generated.* Dated July 9, 1867.

This invention is not described apart from the drawings. —Patent completed.

2005 W. E. GEDGE. *A regulating level.* (A communication.) Dated July 9, 1867.

This level has the property of showing by means of an adjusting screw, a spring, a dial, and an index, the degrees of inclination of slopes or inclines with precision. It is composed of a fixed plate intended to be laid on the incline. At the end of this plate is fixed the level by a pin, or a hinge, so that it may be made to oscillate to preserve its horizontal position. It will be evident that the more rapid the incline, the greater will be the opening of the angle formed by the level and its plate, and there is, therefore, placed at the end of the level a dial which, acting as a tell-tale, shows the degrees of opening of the level, and gives per contra the difference which exists between the incline on which the level is placed and the horizontal. The head of the adjusting screw is divided, so as to give the fractions of an inch, or other measurement, which will be indicated by an index placed on the level.—Patent abandoned.

2006 G. GABILLON. *A process to prepare and preserve paper and tissues with a solution of perchloride of iron, intended for stopping the bleeding of wounds.* Dated July 9, 1867.

The patentee claims the preparation of paper or tissue of any suitable kind with perchloride of iron, as described, to be used as a very convenient and efficacious hemostatic agent; and he claims, also, the means of preventing the paper or tissue thus prepared from being destroyed by the action of the air, by folding and wrapping it up in a piece of waterproofed taffeta, prepared with an addition of resinous substances, as described.—Patent completed.

2007 W. AVERY. *Improvements in boxes or cases for holding packets of needles, and for other like uses.* Dated July 9, 1867.

The patentee claims making the boxes or cases of sheet metal, and providing them with perforated metallic diaphragms or divisions.—Patent completed.

2008 A. SHANKS. *Certain improvements in machinery for making rivets.* Dated July 9, 1867.

Provisional protection has not been granted for this invention.

PROVISIONAL PROTECTIONS.

Dated October 17, 1867.

2907 W. B. Adam, Woodstock Lodge, Granville Park, Blackheath, engineer. Improvements in locomotive engines, vehicles, and appendages thereto, for better and safer working on railways, tramways, and common roads.

Dated December 21, 1867.

3631 B. Browne, King William-street. Improvements in the construction of camp or folding bedsteads. (A communication.)

Dated January 8, 1868.

82 J. Tucker, Old Lenton, near Nottingham, starch manufacturer. Improvements in dressing fabrics and yarns.

Dated January 15, 1868.

135 W. Ayliffe, Cropthorne, Worcestershire, farmer. Improvements in boats, and in the means of steering the same.

136 J. Williamson, White Lion-court, Cornhill, Lloyd's surveyor. Improvements in bolting or fastening one part of a ship or vessel to another.

Dated January 20, 1868.

191 J. Davies, High Park-road, Smethwick, near Birmingham, mechanical engineer. Improvements in machinery for shaping malleable materials, and in apparatus for constructing the same.

193 W. Firth, Rose Villa, Viewforth, Edinburgh. Improvements in the application of vulcanized or unvulcanized india-rubber in the construction of pumps, enemas, syringes, spray producers, and such like instruments.

195 R. Carling, Manchester, and T. Carling, Bolton, mechanical engineer. Certain improvements in lubricating the interior frictional surfaces of steam or other motive power cylinders.

199 A. M. Clark, Chancery-lane. Improvements in steam boilers. (A communication.)

201 J. Parsons, Birmingham, gun barrel manufacturer. Improvements in certain parts of double-barrel breech-loading firearms.

Dated January 21, 1868.

207 J. L. Davies, St. Ann's square, Manchester. Certain improvements in the method of retaining and securing corks or stoppers in bottles or vessels containing aerated liquids, and in apparatus connected therewith. (A communication.)

215 J. J. Long, Glasgow. Improvements in machinery or apparatus to be used in the manufacture of matches or other similar articles.

Digitized by Google

215 J. H. Johnson, Lincoln's Inn-fields. Improvements in furnaces. (A communication.)
219 G. T. Bousfield, Loughborough Park, Brixton. Improvements in liberating the colouring matter of madder and similar vegetable substances, from the ligneous matter or cellulose with which it is combined in the plant. (A communication.)

Dated January 22, 1868.

221 F. L. H. Danchell, Horwich, Lancashire, civil engineer. Improvements in machinery and apparatus for preparing, shaping, and drying peat, and other vegetable and mineral substances.
223 P. Harrower and J. C. Stuart, Glasgow. An improved spray producer, for the production of medicated vapours.
226 W. Thompson and T. Stather, Kingston-upon-Hull, engineers. Improvements in mills for grinding or crushing.
228 S. Bennett, Richmond-road, Dalston. Improvements in means or apparatus to facilitate the drying of grain, seed, brewers' grains, and other matters.
229 E. Tomlinson, Hatton-garden, Holborn-hill. Improvements in means and apparatus for ornamenting, printing, colouring, enamelling, staining, and manufacturing articles from wood and other material.
230 R. Needham, Dukinfield, Chester, engineer. Improvements in the valves of steam engines.
231 T. Goune, Pall Mall, Capt. in the 17th Lancers. An improved canteen.
232 C. S. Barker, Gloucester-road, Regent's Park, organ builder. Improvements in the construction of organs.
233 T. W. Gray, Margaret-street, Limehouse. Improvements in lightning conductors.
234 W. Dennis, Aldermanbury, merchant. Improvements in letter boxes, letter pillars, and such like depositories.
235 T. Cook, Penfold-terrace, Crabtreeshot-road, Peckham. Improved machinery for uniting together materials employed in the manufacture of boots and shoes, saddlery, driving bands, and such like articles as require to be strongly united together.

Dated January 23, 1868.

236 T. Rowley, Manchester, traveller. Improvements applicable to the soles and heels of boots, shoes, clogs, and other coverings for the feet.
237 W. Oram, Salford, hydraulic engineer. Improvements in apparatus to be employed for heating buildings, and for other heating purposes.
238 D. Y. Stewart, Glasgow, ironfounder. Improvements in the manufacture of cast-iron pipes and similar articles, and in the moulds and arrangement of apparatus connected therewith.
239 H. Hodge, Southport, ironmonger. Improvements in gas stoves for heating purposes.
240 G. Kirk, ironfounder, and W. Murray, spinner, Huddersfield. Improvements in self-acting mules and billies for spinning and doubling wool or other fibrous substances.
241 J. C. Sanders, Birmingham. Improvements in door, shutter, and bell knobs and furniture.
242 W. Bottomley, Bramley, near Leeds, machinist. Improvements in milling machinery.
244 H. J. Dickinson, North-mews, Henry-street, Gray's Inn-road, billiard table manufacturer. Improvements in tables adapted to be employed for playing billiards or other games with balls, and also for dining or other uses.
245 H. M. Ragland, Fish-street-hill, City. Improvements in tanning hides and skins. (A communication.)
246 G. Allibon, Worcestershire, engineer, and A. Manbre, Baker-street, Middlesex, sugar refiner. Improvements in steam boilers.
247 S. Price, Highbury, An improved mode of, and means or apparatus for, turning on and off the supply of gas to houses, also applicable to turning on and off the supply of other fluids.
248 M. Tildesley, manufacturer, and J. Bird, manager, Willenhall, Staffordshire. Improvements in the construction of furnaces, stoves, and fireplaces.
250 G. Severn, Hampstead-road. Improvements in valvular apparatus for giving vent to, and for excluding air from, casks or other vessels, and in bungs for closing the same, partly applicable as valves for other purposes.

Dated January 24, 1868.

251 W. J. Jennings, Little Bowden, Northamptonshire, permanent way inspector. Improvements in the permanent way of railways.
252 J. and D. Storer, Glasgow. Improvements in vessels or canisters to be used for holding liquids, solids, and other substances, for the purpose of economizing space and freight.
253 A. Small, Glasgow. Improvements in apparatus for removing excrements.
254 E. W. de Rusett, Lewisham, Kent, engineer, and R. F. Dale, Shoe-lane, City, founder. Improvements in water-closets.
255 A. M. Clark, Chancery-lane. Improvements in means and apparatus for lubricating parts of machinery exposed to the action of steam. (A communication.)
256 C. Woodroffe, Hill-street, Rugby. Improvements in travelling post offices and tenders, and in apparatus for delivering and receiving mail bags and parcels.
257 T. L. G. Bell, Plaistow. Improvements in preparing oxide of iron for purifying gas, and in treating the oxide of iron residues to obtain products therefrom.

Dated January 25, 1868.

258 K. J. Winslow, Montpelier-row, Twickenham, civil engineer. An improved method of conveying rotatory motion to axles.
260 J. M. Lewis, Pimlico. An improved apparatus for securing watches, purses, or other valuables, when worn or carried in pockets.
261 C. W. Dixon, Wickham-market, Suffolk, civil engineer. Improvements in rotating slide valves, and for improved suitable modes of applying these said and other rotating valves to certain kinds of engines.
263 C. Kilburn, Holloway. Improvements in the construction of life and swimming belts, jackets, waistcoats, and buoys.
264 C. E. Brooman, Fleet-street, patent agent. Improvements in breech-loading firearms and in the manufacture of ammunition for the same. (A communication.)
265 C. Ritchie, Brixton. Improvements in apparatus for utilizing heat for heating, warming, and ventilating, whether such heat be procured by the agency of steam boilers, furnaces, or from other sources.
266 T. Robinson, Widnes, Lancashire, ironfounder. Improvements in the formation or construction of fortifications.
267 R. G. Wells, Birmingham, aeronaut, and David Jones, manufacturer. Improvements in apparatus for producing optical illusions.
268 E. J. W. Parnacott, Leeds, engineer. Improvements in the manufacture of elastic rollers.
269 A. C. M. Prince, Trafalgar-square, Charing-cross. A new or improved bell pull for door bells. (A communication.)
271 J. H. Johnson, Lincoln's Inn-fields. Improvements in apparatus for melting and heating metals and other substances. (A communication.)

Dated January 27, 1868.

274 A. Middlemist, Saville-street, Hull. An improved apparatus for increasing, regulating, and controlling the heat and draught in stoves and other fireplaces.
275 A. H. Thurgar, Norwich. Improvements in securing the corks of bottles containing champagne and other effervescing liquids.
276 J. J. Hicks, Hatton-garden, Improvements in the manufacture of backs and handles for hand mirrors.
277 T. Dickinson, Lancaster, plumber. Improvements in apparatus for drawing off water.
G. Kellogg, New York. Improvements in hats, bonnets, and other coverings for the head, and in machinery for manufacturing the same. (A communication.)
279 W. E. Rendle, Welbeck street, Cavendish-square. Improvements in structures for protecting fruit trees, vegetables and other plants from frost, cold, winds, or rain, also in heating such and other structures.
280 W. E. Newton, Chancery-lane, civil engineer. Improved machine for grinding and polishing concave surfaces. (A communication.)
281 W. E. Newton, Chancery-lane. Improvements in machinery for forming hat bodies, skirts, and other articles of wool and other fibrous materials. (A communication.)
283 F. N. Clerk, Wolverhampton, manufacturer. Improvements in machinery for the manufacture of washers and other similar articles.
284 J. Roberts, West Bromwich, ironfounder, and J. Morgan, Kidderminster, manager of works. Improvements in joining metallic pipes.

Dated January 28, 1868.

285 W. Tranter, Birmingham, gun maker. Improvements in firearms and cartridges.
286 E. Egersdorff, Baldwin's-gardens, Gray's Inn-road. Improvements in tips for boot heels.
287 H. A. Bonneville, Sackville-streeet, Piccadilly, A new mode of preserving eggs, and improved apparatus connected therewith. (A communication.)
288 H. A. Bonneville, Sackville-street, Piccadilly. Improvements in ribbon looms. (A communication.)
289 W. A. Gibbs, Gilwell Park, Essex. Improvements in mechanism or apparatus for drying wheat in the sheaf and other vegetable matters.
290 W. H. Crispin, Marsh Gate-lane, Stratford. Improved anti-scorbutic biscuits.
295 T. Corbett, Shrewsbury, manufacturer. Improvements in machinery for cleaning and separating grain, and for other like purposes.
297 J. Pearson, Jewin-street, City, oil refiner, and J. W. Young, Portland-terrace, Regent's-park, oil merchant. Improvements in refining or purifying oils, and in the apparatus employed therein.
299 R. J. Moser, High-street, Southwark. Improvements in bellows, applicable especially to portable and other forges. (A communication.)
301 J. H. Johnson, Lincoln's Inn-fields. Improvements in lithographic printing machines. (A communication.)

Dated January 29, 1868.

305 C. A. McCurd, Camberwell. Improvements in sewing-machines.
309 S. B. Ardrey, Manchester, machinist, and S. Beckett, spindle maker. Improvements in velocipedes.
311 D. Law, ironfounder, and J. Wharrie, foreman, Glasgow. Improvements in the manufacture of cast-iron pipes and similar articles, and in apparatus therefor.
313 W. Guise, Redditch, needle hardener. Improvements in scouring needles and other articles made of iron and steel wire, and in apparatus used for that purpose.
315 S. M. Martin, Pinner, and S. A. Varley, Roman-road, Holloway, telegraph engineers. Improvements in electrical train intercommunication, parts of which invention are applicable to electro-magnetic and other electrical apparatus.
317 W. E. Newton, Chancery-lane, civil engineer. Improvements in breech-loading firearms and in cartridges and bullets for the same, (A communication.)

PATENTS APPLIED FOR WITH COMPLETE SPECIFICATIONS.

Dated January 29, 1868.

307 W. Snell, Parliament-street, Westminster. Improvements in steam fireproof safes. (A communication.)
308 W. Snell, Parliament-street, Westminster. An improved fireproof powder magazine. (A communication.)
310 W. Tasker, Halifax. An improved machine for opening and cleaning cotton, applicable also for other purposes. (A communication.)

NOTICES OF INTENTION TO PROCEED WITH PATENTS.

From the "London Gazette," February 11, 1868.

2759 J. G. Jones. Hauling ropes.
2760 G. Allibon and A. Manbre. Conversion of cereal substances into saccharine matter.
2765 R. Fletcher. Castor for furniture.
2766 T. E. Clarke. Bedsteads.
2769 F. Parkes. Nails.
2773 J. H. Nelson and T. Briggs. Heating water.
2776 F. J. Jeffrey. Urinals.
2777 C. Mace. Marine steam boilers.
2778 H. Haschke. Breech-loading firearms. (A communication.)
2789 A. T. Becks. Utilization of Bessemer steel scrap.
2791 S. Johnson. Moulding bricks.
2810 J. Piddington. Pneumatic springs. (A communication.)
2817 R. P. Faucheux. Pipes and cigar tubes.
2821 T. Ollis. Registering apparatus.
2826 J. B. Hulme. Excavating.
2836 J. Barker. Consuming smoke.
2837 J. H. Johnson. Projectiles. (A communication.)
2838 H. Wallwork. Hats.
2845 W. Warren. Street sweeping machines.
2848 T. Blackhurst. Composition to prevent the oxidation of iron.
2852 A. M. Clark. Preparation of extracts of madder. (A communication.)
2854 J. Withinshaw and J. E. Baker. Machinery for working slide valves.
2883 W. Gadd and B. Walker. Narrow fabrics.
2887 W. R. Lake. Loading heavy ordnance. (A communication)
2888 W. R. Lake. Revolving batteries. (A communication.)
2899 A. M. Clark. Producing motive power. (A communication)
3001 F. D. Frost. Rollers for spinning.
3007 W. B. Adams. Locomotive engines.
3017 G. M. Wells. Boots and shoes.
3033 S. S. Maurice. Fastening for neckties. (A communication.)
2971 A. V. Newton. Dredging boxes. (A communication.)
3026 A. M. Clark. Railway brakes. (A communication.)
3138 C. L. Hett. Governors of steam engines.
3178 W. Thompson. Omnibuses.
3510 J. W. Burton. Treatment of fibrous materials.
3516 A. M. Clark. Presses for stamping. (A communication.)
60 G. Warsop. Mangles.
62 G. Warsop. Washing machines.
143 J. J. Ashworth. Looms.
174 H. H. Lloyd. Coffins.
207 J. L. Davies. Securing corks. (A communication.)
218 H. Brinsmead. Thrashing machines.
228 S. Bennett. Drying grain.
237 W. Oram. Heating buildings.
245 H. M. Ragland. Tanning hides. (A communication.)
283 F. N. Clerk. Washers.

The full titles of the patents in the above list can be ascertained by referring back to their numbers in the list of provisional protections previously published.

Opposition can be entered to the granting of a patent to any of the parties in the above list, who have given notice of their intention to proceed, within twenty-one days from the date of the "Gazette" in which the notice appears, by leaving at the Commissioners' office, particulars in writing of the objection to the application.

LIST OF SEALED PATENTS.

Sealed February 8, 1868.

2287 H. W. Withers	2315 J. Shanks and J. Cargill
2288 F. Wirth	2403 J. Newark
2292 W. R. Dawson	2455 W. B. Smith
2293 F. J. Seymour	2572 A. M. Clark
2300 J. Davenport and J. Kitson	2578 W. E. Newton
2305 R. Girdwood	2594 R. Lowe and J. Taylor
2306 R. Edmondson	2643 L. Lenzberg
2311 A. Turner and W. Hemsley	2980 A. M. Clark

Sealed February 11, 1868.

2220 J. H. Johnson	2347 T. Bushby
2310 E. Courtin	2350 E. Ormerod
2318 W. T. Eley	2351 A. F. Baird
2320 H. T. Everist	2356 M. Henry
2322 J. J. Bright	2362 A. Leveson
2323 G. and J. Pilling, and F. Jennings	2370 F. B. Houghton
2331 J. Fawcett	2372 M. Cahen
2332 T. Walker	2381 C. Reitert
2334 W. B. Leachman and J. Holroyd	2384 W. Burrow
2337 J. A. Jones, R. Howson, and J. Gjers	2388 A. Cohen
2341 G. Buxton and S. Bann	2389 J. Murgatroyd
2343 H. Bessemer	2507 J. Howard and E. T. Bousfield
2344 J. T. Way	3110 H. Allman and F. N. Gisborne
	3345 W. R. Lake
	3473 J. Durrans

PATENTS ON WHICH THE STAMP DUTY OF £50 HAS BEEN PAID.

THE

MECHANICS' MAGAZINE.

LONDON: FRIDAY, FEBRUARY 21, 1868.

AMERICAN ORDNANCE.

WHATEVER representations or misrepresentations may have been made on either side of the Atlantic with regard to the performances of American ordnance, it is certain that it comes out very creditably in this respect in the report of the U.S. Chief of Ordnance—General Dyer—just issued. The official facts contained in this report are at once interesting and instructive, and General Dyer demonstrates that the American heavy smooth-bores are "the cheapest and most effective guns possessed by any nation." Let us see how this assertion is borne out by the circumstances of the case. We should, however, premise that—as stated in the report—persistent efforts have been made for some time past in America by ignorant or designing persons to destroy public confidence in the heavy guns which have been provided by the Ordnance Departments of the Army and Navy. Iron castings, placarded as representing the condition of the metal in American heavy guns, have been placed in conspicuous public places, and publications have appeared in prominent journals asserting that those guns were worthless; that they could only be fired with very light charges of powder, and that they would burst if fired a few times rapidly. The Bureau of Ordnance accordingly directed experiments to be made to test the power and endurance of these guns, and it is upon their results that General Dyer takes his strong standpoint. The report states that the 20-inch gun has been fired with a charge of 200lb. of powder and a shot weighing 1,100lb., and the General states that this may be the regular charge for this gun. The range at 25deg. elevation was more than four and a-half miles. The 15-inch gun, about the performances of which, at Shoeburyness, we in England know something, has been fired as follows:—7 times with 40lb. of powder and and a shell weighing 350lb.; 5 times with 50lb. of powder and a shell weighing 350lb.; 70 times with 50lb. of powder and a shot weighing 434lb.; 59 times with 55lb. of powder and a shot weighing 435lb.; once with 60lb. of powder and a shot weighing 434lb.; once with 75lb. of powder and a shot weighing 434lb.; once with 80lb. of powder and a shot weighing 434lb.; once with 90lb. of powder and a shot weighing 434lb.; and 125 times with 100lb. of powder and a shot weighing 434lb. The mean range obtained with 100lb. of powder and an elevation of 32deg. was 7,732 yards. The mean initial velocity of the shot, with the same charge, was 1,510ft. per second. Ten rounds were fired in 35min., which was as rapidly as the gun could be fired with 100lb. of powder and a solid shot. An examination of the gun has failed to detect any enlargement of the bore from firing, neither has the metal been cut away by the powder. In fact, the gun is reported to be serviceable in every respect.

We next come to the trial of a 15-inch navy gun, which has been fired twelve times in 16min. with 40lb. and 55lb. of powder and solid shot without injury. It should not be forgotten that a number of 15-inch navy guns were fired in action several hundred times, and some of them with 60lb. of powder and solid shot. Two of these guns had their muzzles blown off in consequence of the premature explosion of shells in the bores, but no other injury was sustained. A 10-inch gun, the metal of which had a greater initial strain than the maximum limit which had been established, was fired without injury to the gun 18 times with 18lb. of powder and a shot weighing 127lb.; 17 times with 20lb. of powder and a shot weighing 127lb.; twice with 22lb. of powder and a shot weighing 127lb.; 453 times with 25lb. of powder and a shot weighing 127lb.; 120 times with 26lb. of powder and a shot weighing 127lb.; 4 times with 27lb. of powder and a shot weighing 127lb.; and once with 30lb. of powder and a shot weighing 127lb. The only 12-inch rifle gun made for the Ordnance Department was fired 107 times with charges of powder varying from 35lb. to 85lb. and a shell weighing 477lb.; 341 times with charges of powder varying between 35lb. and 80lb and a solid shot weighing 620lb. With 50lb. of powder, the mean initial velocity of seventy-five shot was 1,139ft. per second. This gun is reported as perfectly serviceable. It is a cast-iron gun, cast hollow and cooled from the interior. The cost is stated to be less than one-seventh that of wrought-iron guns. In concluding his report, General Dyer observes:—"While the results of actual trial have satisfactorily demonstrated the strength, efficiency, and reliability of our smooth-bore cast-iron cannon of large calibres, and similar trials have warranted the same expectations in regard to rifled cannon of cast iron, these latter have not as yet been tested to a sufficient extent to authorize their adoption for the service in preference to heavy rifled cannon of any other material. I should not, therefore, feel justified in procuring any large number of these rifled cannon at present, but would prefer to make further trials with such number only of them as may be necessary for that purpose, and to await the results before proceeding to procure the cannon of this kind which our permanent fortifications will require. So important is it, in my opinion, that these trials should be made, that I earnestly recommend that two 10-inch and two 12-inch rifle guns be made at once and fired to extremity, to test their power and endurance."

In glancing over this report we are first inclined to ask, what becomes of the observation Admiral Farragut is reported to have made when in England about the 100lb. charge for the 15-inch gun? We were told that the Admiral, on hearing that at Shoeburyness we were firing 100lb. of powder in the 15-inch gun, said "Ah! you may fire those charges if you like, but we don't do that in America." If they had not done so then, they have since, over and over again, so that the 15-inch gun has proved itself equal to 125 rounds with this heavy charge and a 434lb. shot, besides a long series of lesser charges. With the 100lb. charges the main range, with an elevation of 32deg., was 7,732 yards, nearly four miles and a-half, the initial velocity being 1,510 feet per second. We have, then, from official reports, two material points conclusively established, namely, that the 15-inch gun is fired with a succession of 100lb. powder charges, and that it is capable of sustaining these charges without damage or detriment. Another point raised in England, that this gun could not be fired with sufficient rapidity, appears to be answered very satisfactorily in the report. There we find that a 15-inch gun was fired ten times in 35min. with 100lb. powder charges and solid shot, whilst a navy gun of the same calibre was fired twelve times in 16min. with 40lb. and 55lb. of powder and solid shot. If the performances of the 15-inch gun are thus proved to be in every respect satisfactory, no less so are those of the 20-inch gun. This formidable weapon has been fired with 200lb. of powder and a shot weighing 1,100lb., the range at 25deg. elevation being more than four miles and a-half. This gun and its charge are difficult things for us to realize, but here they are, and here are their results, and, what is more, General Dyer has no hesitation in assigning this heavy charge as that which may be regularly used in this gun. However we may argue down the matter in theory, there is no getting over these practical facts, unless we dub General Dyer a fool, and his report a fiction.

LONDON GAS SUPPLY.

IT seems passing strange that London, the boasted capital of the world, should be so much worse served in the matter of gas supply than scores of provincial towns that might be named. Notwithstanding the enormous, constantly and rapidly increasing consumption, which should enable the gas producers to manufacture an article of the best quality, and deliver it with a profit, at a much lower price than the concerns requiring plant that do comparatively only a fraction of the work, the price charged is amongst the highest, and the quality of gas delivered amongst the lowest, known in the United Kingdom. The gas delivered in London at 4s. and 4s. 6d. per 1,000 feet, and nominally of fourteen candles illuminating power—often not ten, it may be doubted—is greatly inferior to what is delivered in Manchester—twenty-two candle power at 3s. 2d. per 1,000 feet. The charges in freight of coal cannot be the sole reason for the higher price, seeing that better gas is delivered at Plymouth for 2s. 9d. per 1,000 feet than in London for 4s. 6d. At Bradford the price is 2s. 4d. to 3s. 4d.; at Liverpool, 3s. for Cannel gas; at Birmingham, 2s. 7d. to 3s.; Nottingham, 3s., &c.; but scarcely in any city or town is the price so high or the quality as low as in London, where the annual income of the gas companies reaches, if we mistake not, nearly three millions sterling. The enormous profits which ought to be netted must either be squandered profligately or divided illegally, in violation of the statutory limitation of 1860 to ten per cent; or they must fail to be realized with such prices, because of sheer recklessness, ignorance, or inability in the management and manufacture. This grievance of dear and bad gas has long been a subject of loud and general complaint but notwithstanding its having been repeatedly before Parliament, no effective remedy has as yet been provided, and now the thirteen companies that supply London are threatening the perpetuation of the evil, in a bill they have before Parliament in the present session for their amalgamation and the guarantee of their "vested interests."

The exorbitant price paid by the inhabitants of London for the very bad gas served to them is practically a heavy and grievous tax upon a necessary of life. There was no argument applied against the defunct window duty that may not be applied with equal or greater force against this impost, which is the more vexatious indeed that it goes to the enrichment of private individuals, whereas the proceeds of the window duty went into the national purse. Artificial light, as a means necessary to the subsistence, not to speak of the comfort, of thousands of our population, is as essential as the daylight of Heaven, and neither the one nor the other seems to us a proper source from which the national exchequer should draw contributions, or the speculating capitalist his most safe and bountiful dividends. Whether the whole creed of the "Manchester school" may be safely accepted or not we will not venture to say, but in this matter the example of the Manchester corporation is well worthy of imitation. The gasworks of Manchester are amongst the largest and best managed in the kingdom, and the waterworks, of which the same might be said, are the property of the corporation, and any profits accruing from the supply of gas are devoted to public objects. Many splendid street improvements have been effected in Manchester from this source. The citizens of London will regard with general satisfaction the adoption of the same course by the Corporation of London. In their intercourse with the gas companies, the Corporation authorities have had repeated occasion, we

Digitized by Google

believe, to complain of bad faith, and they are now trying to get the matter of gas supply into their own hands, by a bill to be prosecuted during the present session. The bill of the companies for amalgamation offers nothing to conciliate public support; it is a mere ark for the preservation of the proprietors' interests.

The Corporation bill is of a very different character. Its preamble declares its purpose to be to supply the City as abundantly as possible with gas of as good a quality, and at as low a price as circumstances will admit. The professions in the preamble are fairly carried out by the provisions in the clauses. The bill takes powers to purchase the works and mains of the Great Central, the City of London, the Gas Light and Coke, and the West London Junction gas companies. It is proposed to discontinue entirely the manufacture of gas in the City, and to erect new works at North Woolwich. The bill provides that the gas supply shall be of not less than eighteen candles illuminating power; that it shall not contain more than twenty grains of sulphur in any form in 100 cubic feet of gas; and that the gas shall not discolour turmeric paper, or paper imbued with acetate of lead, when such paper is exposed to a current of gas issuing for one minute from an orifice one-fourth of an inch in diameter, at a pressure of not less than half an inch of water. Dr. Letheby's sulphur test is to be employed. The chemical examiner's reports on the illuminating power, purity, and pressure of the gas will be had on request and payment of a small fee by the consumer. The Corporation propose that they should have powers under the bill to supply the City of London and its liberties, and the Metropolitan and Islington markets. The bill is a reasonable and, in all respects, proper document; it will be prosecuted, we hope, with vigour and perseverance, and will evoke such a measure of earnest support as is due to its merits, and as shall induce and justify the Legislature in converting the Bill into an Act.

A QUEER PERIODICAL.

ABOUT two years since a new periodical, ostensibly devoted to the interests of the engineering profession, was started in London. This paper is in every sense so unique in its character, so audacious in its pretensions, so clamorous in its appeals for support, so energetic in its abuse of all those who may chance to differ from it in matters of opinion, and so little scrupulous in its management, that it fairly challenges criticism. Its ostensible proprietor, editor, manager, all in one, is an American; we may add, indeed, an American of the Americans. Steeped to the very lips in the principles of United States' journalism, he might have sat for the portrait of Colonel Diver, as drawn by Mr. Dickens. When we peruse the weekly papers of our Yankee contemporary, we become convinced that Mr. Dickens' sketch was no caricature. The veritable Colonel walks and moves, and has his being, before us, and the picture is very far from not having its humorous side. The air with which our New York author, editor, manager, proprietor, speaks of "We English," is excessively comical—so comical, that if the man, by his writing, did not tend to injure the fair fame of British journalism, we could not resist a hearty laugh; and, besides, he deals so freely in libellous abuse of those who do not, according to his appointed method, secure his good will, that his paper causes no small annoyance to English engineering manufacturers, many of whom, failing to see through the shallowness of his pretensions to real influence as a journalist, hope to keep him quiet by contributing more or less largely to his advertising columns. We have said that his paper is unique, and it is especially unique in that, as a matter of notoriety, its chief supplies are believed to be drawn from the coffers of one of our most eminent steel manufacturers, whose productions, processes, and patents he is never weary of puffing and repuffing, and puffing again *ad nauseam*.

We do not wish it to be supposed that this paper is without some merit. The spirit of pugnacity is largely developed in the British character, and most young Englishmen like a good fight. Children are delighted by the whirling sails of a windmill, and this is the very windmill of literature. Its sails revolve with a mighty sweep, now ascending far into the regions of self-laudatory bombast, and anon sinking into the lower regions—alas that we should have to say it of a thing professedly so noble—of what is idiomatically termed Billingsgate. Each week its readers are treated to something new in the way of denunciation, or if for the moment it should happen that no one has offended grievously, the editor publicly pats himself on the back, and calls himself an excellent fellow. Like little Jack Horner, indeed his favourite refrain is "What a good boy am I!" Sensationalism has hitherto being confined to the realms of fiction, but our Yankee editor, proprietor, manager, has cut out a new path for himself. We guess he has laid out a new track in which he walks alone. He has succeeded in achieving the unparalleled feat of producing a sensational technical journal, and indeed it is no matter for wonder if he enjoys—as he says he does—a tolerable circulation, we presume among the juvenile members of the profession.

Sensation authors could not possibly get on without crime. If there were no murders their occupation would be gone. Our editor finds his murders in the leading articles of our respectable contemporary "The Engineer." "The Engineer," indeed, is far better for him than a murder can possibly be to Miss Braddon or Wilkie Collins. It is not only the murder but the murderer. He pursues it, and hunts it down, and gibbets it week after week with an energy and pertinacity worthy of a better cause. Indeed, we do not know what would become of him if "The Engineer" did not exist. Like Othello, his occupation would be gone, and his paper would cease to be funny. He makes no secret of a wish to bring about the collapse of "The Engineer," but he is injudicious and unreasoning. Like Samson, he would pull down the pillars of the building in which all his nobles sit. The destruction of "The Engineer" could be little short of suicide. For a time it is possible that he might manage to be funny in a gloomy sort of fashion about a well-known author, and he might possibly protract a wretched existence by falling foul of us, or of "The Builder," or of the "Practical Mechanics' Journal," but "The Engineer" is his mainstay, and, that gone, it is easy enough to see that he would of necessity be involved in the crash. Seriously speaking, the true character of the journal to which we refer deserves to be better known. We have laughed at it, and so no doubt have a large proportion of its readers. And our contemporary "The Engineer," staid, and serious, and truly representative, if it deigns to take any notice whatever of the lucubrations of our Yankee editor, no doubt does the same.

But the journal, such as it is, possesses just enough of cleverness to be mischievous. It is got up, too, by one who does not trade on his own bottom, as merchants say, and therefore it is lavishly illustrated, and rendered as attractive as pictures can make it. If the engravings are not always very refined, or very accurate, or very well selected, who among such readers as it has is likely to know the difference? It so bespatters itself with praise, too, that the unwary are likely enough to be led to believe that it is influential. We know as a fact that many engineers advertise in it without receiving any cash in return in the shape of orders, and woe betide the man who once advertises himself in its advertising pages and dares to draw back. One firm brought out a donkey pump some time since, and advertised in the paper under consideration for three months without obtaining a single order, as was to be expected from the nature of its circulation. In a rash moment they withdrew their advertisement. The week following, the world was told that Messrs. Brown's donkey pumps were "asinine abortions," and about once a month since on the average we have had the same story repeated in different forms. Last week the firm in question took their revenge. They published dozens of testimonials in favour of their productions, and with admirable satire published also some of the worst accusations which had been brought against the pump in question by our American friend, thus putting his opinions on record as very directly opposed to those of the most extensive employers of steam power and boiler feeding apparatus in the kingdom.

The effect of the author's lucubrations, too, is, unfortunately for himself, signally impaired now and then by curious inconsistency. While an advertisement is *in nubibus* he is usually excessively civil to his fish. If the fish slips off the hook, he pelts him with stones, and thrashes the stream into a perfect froth of mud. A notable fish was the advertisement of an eminent maker of wood-working machinery. We are told one week that this machinery was first-rate in the design of the framing, but the expected advertisement did not come. One week we had the bait; very shortly afterwards we had the stones. The handiwork of the firm was denounced even more vigorously than it had been praised. Our editor was determined that they should not be advertised by him; so, determined that, against all the rules of civilized journalism, he consigned a temperate letter of remonstrance and explanation to his waste paper basket. From his tribunal there is no appeal.

Our American friend has a hobby too—a hobby which is ridden very nearly to death. This hobby is Mr. Bessemer's process. No such process and no such steel ever was heard of before. The process is so magnificent, and the steel is so good, and Mr. Bessemer is so great a man that the £200,000 a-year which that gentleman receives as royalties is not sufficient reward. What a disgrace to the age that he is not made a baronet! Not a knight, dear reader; that is good enough for a man of science, but not good enough for Mr. Bessemer. The unfortunate "Engineer" ventured some time since to hint that we did not know all about steel rails yet, and that certain facts could be urged against their use. This was really an opportunity for our friend. The Yankee eagle screamed and danced on his perch till his feathers fell out, but, strange to say, "The Engineer" has survived the onslaught. Steel rails are being very slowly adopted, and many highly influential trade journals are endorsing its opinions. "The Engineer" offended again by venturing to criticise and explain Mr. Hargreaves' process of steel making. Then the eagle was a sight to be seen—not described. And yet Mr. Hargreaves has survived, and "The Engineer" too. The week before last, "The Engineer" had the temerity to publish an article full of playful *badinage* plainly indicating Mr. Bessemer's connection with the journal in question, which journal rose with the occasion, and denounced "The Engineer" with a vehemence only equalled by a want of knowledge of the Latin grammar. And so we suppose the play will go on to the end, and our Yankee contemporary will continue to delight appreciative but limited audiences.

At first sight it may appear strange that Mr. Bessemer should lend his aid to such a production as this, but the wonder ceases when we recollect the foolish horror which some men have of being publicly criticized—a horror increased tenfold when it is known

Digitized by Google

that the critic is at once unscrupulous and possessed of a certain fund of cleverness. We see the operation of this terror in the fact that many good names are included among those who advertise in our American friend's pages. They may chance to get an order which will pay all the cost of the advertisement, and they may consider peace and quietness cheaply purchased at such a price. Whether the immunity from criticism is purchased too dearly by an inevitable loss of self-respect each man will decide for himself. It is to be regretted that any journal conducted on such principles should receive support, and people will possibly find this out after a time. As for ourselves, we should hardly have dared to write this article did we not know that the means of safety were in our grasp. If our New York editor, proprietor, manager, is only a little savage next week we think we can survive it. If he is very ferocious we shall adopt the means of defence provided. We shall send him a good long advertisement, paid in advance.

THE ROYAL NAVAL ENGINEERS.

JUST twelve months since we uttered a plea on behalf of the engineers of the Royal Navy, pointing out various disabilities under which they laboured, and from which they very properly sought to be relieved. Some of these grievances, we are happy to say, have since been redressed, although others have been left unnoticed. The Royal Naval Engineers have again recurred to these unremedied points in a very temperate and straightforward statement, in which they confine themselves strictly to those points which bear directly and certainly most injuriously upon their interests. The first request is that chief engineers should be allowed to reckon for increase of full and half-pay the whole of the service rendered previous to attaining that rank, instead of only four years, as at present. To our minds, nothing appears more reasonable than this request, and for many reasons. In the first place, an engineer, on entering the Navy, must be possessed of the necessary educational and practical attainments to qualify him for immediately entering upon a course of arduous and responsible service. This service extends over a period of from twelve to fifteen years before he attains the rank of chief engineer. The average is now above thirteen years, and is, we understand, rapidly increasing. In many instances a very large portion of that time is served in the capacity of senior engineer of a small vessel. Here, being in charge of the machinery, the officer is called upon to perform the duties and incur the responsibilities of chief engineer. Now, it is certainly a great hardship that so large a portion of time, during which valuable service has been rendered, should be lost.

It further appears that the average age at which an engineer officer arrives at ward-room rank is much higher than is the case with officers belonging to any of the collateral branches of the Navy. This disproportion threatens to become greater in future, unless means are devised to insure a more satisfactory flow of promotion. What the present rate is may be judged from the fact that during the past two years the promotions to the rank of chief engineer have not reached one per cent. upon the number of juniors! It thus appears probable that the long period now required to attain the rank of chief engineer will be much extended in the future. Another point which should not be lost sight of is that in consequence of not having been promoted at an earlier period of life, the majority of present chief engineers will be unable, under existing regulations, to attain the highest rate of full pay allotted to that rank sufficiently early to realise any other advantage than the increased rate of half-pay or retirement contingent upon its attainment. Indeed, a large number will fall short even of that benefit by being unable to render the amount of service required, viz., 21 years in the rank of chief engineer. The result is that the rate of full pay, instead of being enjoyed for a moderate period as a reward for long and meritorious service, is practically unattainable, except by a limited few, who, from exceptionally fortunate circumstances, have reached the rank of chief engineer at an age considerably below the average. Now, the Admiralty view of the case is that an assistant engineer on first entry in the Navy can only be regarded as inexperienced. But this is no answer to the present question. Our authorities must allow that four years is a most inadequate recognition of the long period of service rendered prior to the attainment of the rank of chief engineer. This is the more apparent when we find that the Queen's regulations and the Admiralty instructions require that an assistant engineer must serve at sea for three years, and be fully competent to take charge of a watch at sea when steam is up, before he can receive his first promotion. In common fairness, then, we say that permission ought to be given to reckon for increase of full and half-pay the whole of the service rendered previous to attaining the rank of chief engineer.

The next point is one to which a passing allusion has already been made. It is that means may be devised for insuring a more satisfactory rate of promotion to the rank of chief engineer. The simple facts bearing on this subject are that only five officers were promoted to that rank in 1866 and twelve in 1867 from a body numbering more than 500, exclusive of all first and second class assistants. Those so promoted had served from six to eight years in the rank of engineer, and about fourteen years in all ranks. Of course, these gentlemen feel keenly that every day served over four years is, as far as future recompense is concerned, utterly lost to them, and that however long they may serve in that position—from no fault of their own—they receive no increase of pay. To remedy this unsatisfactory condition of matters, and to improve the rate of promotion in some degree, it is suggested that chief engineers should be allowed to retire at fifty years of age with an increase of half-pay beyond that to which an officer retiring would be entitled by service. The reasonable expectation is that this would result in the retirement of a number of officers, and, consequently, of the promotion of a corresponding number of engineers. It is further suggested that chief engineers should be appointed to all vessels in which other departmental chiefs are borne. If, notwithstanding the adoption of these, or any other measures, an engineer should remain in that position after duly qualifying for the rank of chief, it is only fair that he should receive an increase of pay. We are aware that there are a few difficulties in the way of dealing with these matters in the manner suggested, but they are by no means insuperable, and we think that the Admiralty Lords could easily find a way by which these grievances could be redressed. It is a matter for serious consideration, and we appeal to those within whose province its consideration comes to deal equitably with the question, and to ameliorate the present position of the naval engineers, which is assuredly one of great hardship.

It now only remains to draw attention to one more request which the naval engineers prefer, and that is that an increase of full and half-pay should be allowed at shorter intervals than five years, as at present. This request was made last year, but not having been acceded to is now repeated. And it is a matter worthy of every attention; for, as the case now stands, a real grievance is experienced by those officers who, from illness or other cause, may be removed, temporarily or permanently, from active service at a time when a large portion of the required term of five years has been served. By the present system, these officers are, for want of the remaining portion of the term—perhaps only a few weeks, or even days—deprived of a very large fraction of their income, being in some cases as much as one-fourth. The old system of requiring five years' service to be rendered for each increase of full and half-pay has been broken through in the case of other classes of officers of rank corresponding to that of the naval engineers. We therefore trust that this will be borne in mind, and will lead to a favourable reception of so fair and reasonable a request as that we have considered.

In urging upon the Admiralty authorities the necessity of taking some steps to remedy the very defective condition of the naval engineers' regulations, we would not be considered as blind advocates of the question. Apart from the justice and moderation of the requests, we look at the duties and responsibilities of those who prefer them. Progress is everywhere the order of the day, and nowhere is improvement more general than in the machinery of the vessels of the Royal Navy. And this refers not only to propulsion, but to various other purposes to which machinery of a delicate and complicated nature has been applied on board ships of war. The great extension in this direction has materially increased the duties and responsibilities of the engineers, upon whom the supervision and maintenance in a proper state of efficiency of this machinery devolves, and who have to perform any repairs required at sea. Hence the services of experienced and skilful engineers are of continually increasing value to the country, and whilst anything like senseless complaining ought to be scouted, such perfectly equitable and moderate requests as we have been discussing ought to be granted, and the unquestionable hardships which they represent ameliorated.

DOCKYARDS OF THE MEDITERRANEAN.

SITUATED upon the shore of a tideless sea, the little town of Seyne presented, nearly a century ago, advantages for the construction of vessels that were not disregarded by the somewhat primitive class of shipbuilders that carried on their business at that port. About the year 1790 it could boast of two or three workshops, where the description of vessels constructed was upon a very limited scale. With a liberality not usual among corporate communities, the authorities of La Seyne exacted no toll or duty from anyone who chose to lay down a keel, and when the labours of the temporary occupant were accomplished, the slip was at the service of the next comer. This truly happy method of managing business did not, however, continue very long. In the year 1830, the first steamship was put upon the stocks, no longer by simple right of "first come first served," and in about ten years subsequently, when the dimensions of the vessels assumed a respectable size, a harbour was constructed. The building of iron ships commenced twenty years ago, but it was not until 1856 that a company took up the management of the works, expended a considerable amount of capital upon them, and started business upon a large scale. Among their early improvements was the construction of a wet dock, measuring 420ft. by 160ft.; the deepening of the canal leading to the workshops, so as to allow of vessels drawing a good deal of water coming right up to them; and the reclamation of a large quantity of land lying immediately adjacent to the Mediterranean, and which has since been turned to good account for erecting additional warehouses and sheds. At La Seyne the keels of a dozen vessels can be laid down contemporaneously upon the inclined slips, between which the forges and every

Digitized by Google

mechanical appliance necessary for their completion are placed. In addition to the water communication, a railway runs to different parts of the premises. Towards the eastern side is situated the timber store, and that of the iron towards the west, in the latter of which are kept the plates, angle, tee, channel, and other sections of iron usually employed in marine engineering. A continual supply of these modern indispensable accessories to shipbuilding is forwarded from the well-known establishments of Creusot, Terre-Noire, Saint-Chamond, and others, which furnish material of an equally good quality, but which have not yet attained to the "prestige" of those mentioned. Our columns of last year contain full information respecting those great "foci" of foreign manufacturing industry. The thickness of the plates supplied varies from 0·12in. to 1·20in. Most of the angle iron is the produce of the works at Alsace, owned by M. Dupont-Dreyfus, and are invariably sent in straight lengths, any bending being effected upon the premises at La Seyne. All the iron received is tested, numbered, and classed accordingly. Were the plan of testing iron adopted universally by our English firms, who use it for constructive purposes, it would tend to promote a greater degree of confidence in the material among engineers than at present exists.

So soon as the working drawings of a vessel have been got out, the component parts are all drawn to a scale of full size upon the floor of a large room called the tracing room, which, besides ensuring great accuracy in the workmanship, frequently leads to advantageous modifications and alterations which escaped the original designer. Timber is rarely employed at La Seyne in the actual shell of a ship, its use being confined to the construction of the masts and planking for the decks. The ribs, after being drawn to a full-size scale, are modelled in wood, which serve as templates for the bending of the iron. The ribs having been curved to the proper form, are punched for rivets, and numbered consecutively. Solid blocks of timber, bound together by an angle iron, the angle of which is very obtuse, constitute the keel. The lower rib of the angle iron is the real keel, and the upper one is a portion of the side of the vessel, and to which the lower part of the ribs is attached. A punching machine, and a treble cylindrical bending rolls, are the principal machinery required for the preparation of the plates of vessels destined simply for the purposes of commerce. The introduction of armour-plated vessels necessitated the erection of more powerful adjuncts to work the solid plates intended to stand the test of powder and shot, the chief implement being an hydraulic press capable of exerting an enormous pressure. Among the ships of war built at the workshops of La Seyne may be mentioned the "Numancia." As this vessel has obtained some little notoriety, a short account of her will be interesting to our readers. She is an armour-plated frigate of nearly 7,500 tons, and was built for the Spanish navy. In the service of that nation she figured in the attack upon Callao, and is remarkable as being the first European armour-plated vessel that passed the Straits of Magellan, and floated upon the waters of the Pacific Ocean. She occupied a period of nearly two years in building, is entirely of iron, and carries no ram. Immediately above the line of flotation there are fixed two longitudinal partitions reaching to the gun deck, and constituting, with the external skin of the vessel, two extensive watertight compartments. Five additional partitions of a similar character, but placed at right angles to the two described, complete the system of defence against any ingress of water that might arise from a ball penetrating the hull below the water line. The plates, which were manufactured at Rive-de-Gier, are a fraction over 5in. in thickness, and cover the whole of the sides, which have a total length of 320ft. A backing of teak, 16in. thick, serves to support and hold the plates. Four times their nominal power is the working ratio of the "Numancia's" engines; the diameter of the cylinder is 7·03ft., and the stroke of the piston 4·28ft. At the assault upon Callao the plates of the "Numancia" successfully resisted the impact of shot weighing 330lb. fired from the Blakeley gun, one only of which pierced her armour and lodged in the teak backing. The cost of this vessel, without including the item of artillery, was upwards of £300,000.

Another ship of a similar nature was constructed at La Seyne for the Italian Government, named "La Regina Maria-Pia"; she was built in sixteen months, and took part in the battle of Lissa, coming out of the engagement with no greater damage than the indenting of some of her plates, which are 4·8in. thick, to the depth of a couple of inches. Her length over all is 250ft.; her displacement is nearly 4,500 tons, and her cost, exclusive of war material and cannon, £175,000. Upon a similar plan the sister vessels, "La Terrible," "La Formidable," "Le Palestro," and "Le Varèse," were built and launched from the same ways. The establishment at La Seyne has also been called upon to extend its aid to the Brazilian Government, which forwarded an order for an armour-plated corvette, which was finished in the short space of time of one year. Her chief feature was very small draught, as she was required to navigate in 12ft. of water, whereas vessels of this description usually draw double that depth, and frequently a good deal more. The plating extends to the upper deck, and there are two transversal partitions. A number of gunboats designed expressly for river warfare were built at the establishment under notice, for the Ottoman State, and also those, capable of being readily taken to pieces and put together again, which were intended to be employed upon the Lac de Garde, at the commencement of the first Italian campaign. The largest screw steamer constructed in France was launched from the port of La Seyne, and was a yacht, completed in twenty months for the Viceroy of Egypt. She was christened the "Masr," and was 380ft. in length by only 40ft. in breadth, and attained a velocity of 14½ knots per hour. Her fittings and appointments were on the most sumptuous scale, but her principal feature was the arrangement of the machinery. To impart a greater velocity to the screw, the shaft is connected with a pinion which is acted upon by a multiplying wheel, in a manner very similar to that adopted in the "Gharbie," which enjoys the reputation of having made the fastest run on record from Marseilles to Alexandria. The cost of the "Masr" was £150,000. We shall recur to this subject next week.

PHOTOGRAPHY.

THE ELECTRIC LIGHT FOR ENLARGEMENTS—THE PRESIDENT OF THE PHOTOGRAPHIC SOCIETY—PHOTOGRAPHIC RECORD OF EARTH CURRENTS AT THE ROYAL OBSERVATORY.

LAST week, on Thursday afternoon, Professor Tyndall announced, at the Royal Institution, that Mr. Ladd, the philosophical instrument maker, is going to construct a small gas engine to be used in connection with his magneto-electrical machine, for the production of the electric light. The want of some such means of obtaining the electric light has been long felt by photographers. The cost, maintenance, and poisonous fumes of the Grove's battery prohibit its commercial use for the production of photographic enlargements: hence Mr. Woodbury and others who use the electric light in photography, adopt one of Wilde's, Ladd's, or Siemens' magneto-electric machines, driven by steam power. Of course the fitting up of a steam-engine simply for photographic purposes is a thing rarely done, and those who produce enlargements in moderate quantity usually employ the light of the sun, or the rays of the oxy-hydrogen lime light. For many processes the latter light is not sufficiently rich in chemical rays to answer well, whilst for other processes it is nearly everything that can be desired. When the light of the sun is used for enlarging purposes, the operator is very dependent upon the weather, changes in which affect his interests most seriously.

A magneto-electric machine which will give a brilliant electric light when turned by hand has often been demanded by photographers, but such a powerful current as this can never be so obtained, because the law of the conservation of energy forbids that human muscular strength can ever produce in any machine more heat than is generated in the original source of power, the human body. Hence a little gas cylinder and piston attached to a magneto-electric machine will make it a very valuable instrument, especially if Mr. Ladd can make the whole arrangement portable enough for lecturing purposes. Such a machine would give the death-blow to Grove's battery in the great majority of cases where a powerful current is needed.

There are three kinds of novel magneto-electric machines now in the market. The first of these is the great invention of Mr. Wilde, which attracted so much attention two years ago, in which the induced current from permanent magnets is made to excite a row of electro-magnets, so that the armature of these secondary magnets gives off a powerful current of electricity, which may be at once applied to experimental purposes, or made to excite a third row of electro-magnets, and so on *ad infinitum*. Messrs. Siemens and Wheatstone next invented a curious machine, wherein the trace of residual magnetism in a soft iron electro-magnet was made to act upon the armature, and the wires from this armature, being carried round the electro-magnet, of course increased the intensity of the magnetism already present there. This in turn increased the power of the current from the armature, so that by constantly turning the handle, the quantity of electricity increased, according to the compound interest law, till at last a powerful current was obtained. The third machine is that of Mr. Ladd, and was invented by one of his assistants. By this plan, the electro-magnet is fitted with a double armature. The current from one armature is used to increase the power of the electro-magnet, as in Siemens' and Wheatstone's machine, and the current from the second is the one used for experimental or commercial purposes. Yesterday week, this machine, when turned by hand, heated seven inches of platinum wire ·01 inch thick to redness. It also gave flashing sparks of the electric light between carbon points, but did not give continuous illumination, for the reason already mentioned.

Of the comparative merits of these machines for photographic purposes it is too early yet to speak. Mr. Wilde's must be driven with great velocity, and this tells upon the bearings, but he is now manufacturing a new instrument, which will shortly be introduced into the market. Mr. Ladd's is a strong machine, little liable to get out of order; but he also, as already stated, is about to make further improvements. Mr. Woodbury, who has just been fitting up enlarging apparatus for M. Disderi, the celebrated Parisian photographer has there employed a magneto-electric machine sold by the Alliance Company of Paris. This machine cost about £250, and is driven by one of Lenoir's gas engines, at a cost, at the present rate of working, of a shilling per hour for gas, and twopence or threepence for carbon points. In a few months, when the improvements now contemplated are carried out, it will be easier to speak with certainty as to the relative merits of the different machines.

Sir Frederick Pollock, F.R.S., ex-Lord Chief Baron, has since his retirement from office devoted more of his time to mathematics, photography, and other favourite scientific pursuits of his younger days. As President of the Photographic Society of London, he has of late more frequently attended its meetings, and last week, on Thursday evening, a paper of his, on "The Mysteries of Numbers," was read at a meeting of the Royal Society. Some little amusement was caused at that meeting by the appearance of one of the "Daily Telegraph" staff to take down the substance of Sir Frederick Pollock's paper, because the contribution consisted wholly of abstract mathematical researches, impossible to be put in popular form for the readers of any daily journal. The reporter, however, was not "beaten," for the secretary, chancing to mention the title of a paper by the Astronomer Royal on "Earth Currents," gave him an opportunity of explaining last Friday,

Digitized by Google

in the "Telegraph," how the movements of these wandering currents are registered by photography.

In a darkened room in the meteorological department of the Royal Observatory at Greenwich, the Astronomer Royal fixed, some two or three years ago, a sensitive little galvanometer, with reflecting mirror, to register earth currents by photography. One end of the wire of this galvanometer is connected with the earth, and the other end with a telegraph wire, which, after running several miles along a neighbouring railway, is again connected with the earth. Now, currents of electricity are continually running to and fro in the earth, and sometimes these currents enter the telegraph wires; also, when they are strong enough, they overpower the ordinary working batteries, and send unreadable messages on their own account. Such disturbances sometimes stop for a time all messages and news, and on one exceptional occasion caused a panic on the Stock Exchange, by delaying news of importance. Being a source of great occasional loss to the telegraph companies, the endeavour of electricians has always been to neutralize and get rid of the currents as soon as possible. The object of the apparatus in Mr. Glaisher's department at Greenwich, is, on the contrary, to watch and examine all the movements of these earth currents. From the description already given, it will readily be seen that as currents from the earth flow through the wire erected from Greenwich Observatory, the needle of the galvanometer shows the direction, and approximately the strength, of the current. On the little magnetic needle a mirror is mounted, and a ray of light from a steady flame, after falling upon the mirror, is reflected as a spot of light upon a sheet of photographic paper. Hence, as the needle moves, the ray of light moves to and fro upon the paper. This sheet of sensitized paper is fixed round a cylinder of ebonite, which, by clockwork, makes one revolution every twenty-four hours. At the end of the twenty-four hours the paper is taken off the cylinder, and a fresh sheet substituted. The record upon the first sheet is then developed in the usual way, and a zig-zag dark line passing across it from end to end shows the movements of the galvanometer needle and spot of light during the past twenty-four hours. The darkened room, in which this self-registering apparatus is at work, is built without iron nails, and this metal is used nowhere in the room, so that the magnetic instruments shall not be disturbed by artificial causes. In a communication made by Professor G. B. Airy, F.R.S., to the Royal Society, a fortnight ago, he made known the fact that the declination magnet and the earth current galvanometer are affected at quite, or very nearly, the same time, showing some relationship between the two phenomena, the causes of both of which are at present a perfect mystery to men of science.

TELEGRAPHY.

INDO-EUROPEAN TELEGRAPH.

THE growing importance of our Indian territory, and the vast commercial interests of this country, with its dependencies in and beyond India, render a sure and speedy system of communication every day more and more necessary. The great importance of our relations with India cannot be overrated, and it was undoubtedly this that led our Government in 1859 to promise a guarantee to the line of telegraph laid from Suez to Bombay. Unfortunately, that line lasted but a brief period, and owing to the necessary delay that took place in submerging so long a line, by the time the last section was laid, one of the earlier ones had failed, and through communication was never realized. A portion—that from Suez—was, after the laying of the Malta and Alexandria cables in 1861, diverted to Jubal, an island in the Red Sea, and messages were sent to and from that place, the mail boats calling there on their passage. This reduced the time of communication considerably, and our merchants and others were enabled thus to send at least a week's later news.

This time has, through our Government laying a cable along the Persian Gulf, been considerably shortened, and messages have been sent since the beginning of 1865, at various speeds, ranging from one day to two weeks. This submarine cable starts from Fao, at the mouth of the Euphrates, in he Shat-el-Arab, to Bushire, at the head of the Persian Gulf, thence down the Gulf, with stations at Mussendom and Gwadur, to Kurrachee, where it joins the system of Indian telegraph to Bombay and Calcutta. Previous to the laying of the cable, arrangements had been made with the Turkish authorities, and a line constructed from Constantinople to Fao, partly at our expense and partly at that of the Turkish Government. Arrangements were also made for an alternative line from Bushire, through Persian territory. By this line messages leaving England pass through the various continental systems to Constantinople, and from thence through Asia Minor to the cable. On the whole, this route has been working satisfactorily for some time, but even now it is subject to interruption, continuing on some occasions for some time. The interruptions formerly were more frequent and lasting on the Indian portion between Kurrachee and Bombay, owing to the bad construction of the lines. These, we are happy to say, are now greatly improved. Other interruptions took place through the breaking of the submarine cable, but the wise precaution of having a repairing ship on the station has prevented them from causing too serious a stoppage to traffic. For a long distance the wires pass through an uninhabited portion of the country in Asia Minor, where accidents have occasionally happened, and great delay, on account of the want of transport, has been the result. A second line has lately come into use, that through Russia and Persia to Teheran, and thence to Bushire. This line, during the late interruption in the Turkish route, was found most useful, for by it messages were continually arriving of the previous day's date, but this route, from the nature of our convention with Turkey, cannot be constantly used; besides, it is subject to similar interruptions to the Turkish lines. From the time a message leaves England it is entirely without our control until it arrives at the Persian Gulf. During that time it passes through various administrations, through the hands of numerous clerks speaking different languages. Can it be wondered, then, that messages, when they arrive at their destination, are frequently rendered so unintelligible as to be perfectly useless. Under such circumstances the number of telegrams must of necessity be less than under a perfect and good system. In mentioning these errors that take place, we must except that portion of the transit that passes through the hands of our own operators in the Gulf, for, from examination and statistics, it is proved that a very small percentage of error is due to that section. What, then, is really required is that a message should be entirely throughout its route under the control of the staff of one of our own administration. Until such comes to pass we cannot hope for that perfect system of telegraphy which the growing interests of our political and commercial relations with our Indian empire demand.

With this in view, negotiations have been for some time on foot for the establishment of a line of telegraph through Europe and Persia, so as to join our existing system in India, and we are now happy to announce that matters have been so satisfactorily arranged that we trust ere long to see commenced the erection of lines which shall place the entire control of a message throughout its route under one management. It is to the Messrs. Siemens principally we owe this result, and we now place before our readers the principal points of their scheme, which, from the features we have mentioned, command our greatest attention.

Conventions and concessions have been obtained from the various governments and authorities by the Messrs. Siemens which will enable them to erect a double wire system from England through a most direct route to Teheran, where they join the system now in connection with the Persian Gulf cable. Their interests and concessions in the matter they propose to hand over to a private company which shall be formed for the express purpose of finding the necessary funds for erection, and of undertaking the management of the lines. The proposed route will be as follows;—Two wires throughout, commencing at Nordeney, an island in the German Ocean on the Prussian coast (late Hanoverian), through Hamburg and Berlin to Thorn on the Prusso-Russian frontier, thence through Russia *via* Warsaw, Odessa, Kertch, and Poti, to Tiflis. from there through Persia to Teheran.

The Prussian concession gives the company the right of landing its own cable on the North German coast, but provisional arrangements have been made with the Electric and International Telegraph and Reuter's Telegram Companies securing to the company the use of two well insulated wires between London and the Prussian coast, including office accommodation in London. In consideration of this accommodation a royalty will be paid on each message. By the Prussian concession the Prussian Government undertake at its own cost the construction of a special double line connecting Nordeney with the Russian frontier at Thorn, and to reserve it for the exclusive use of the company in good working condition on payment of a message royalty; this, as well as in the Russian conventions, will be reduced should the through rate to India be materially reduced; and all Indian messages will be handed over to the company.

By the Russian convention the company are authorized to construct a double line from the frontier at Thorn to the Persian frontier at Tiflis, with stations at Warsaw, Odessa, Kertch, Poti, and Tiflis, and by the Persian concession, lately obtained, the right of constructing a similar line from the Russian frontier to Teheran.

The proposed line is to be constructed principally with iron posts, and in the most substantial manner; a cable of three conductors will have to be laid between Kertch and Poti, in the Black Sea, over a distance of about 250 miles, in order to avoid the Circassian Mountains, where the existing lines are subject to interruption; the line when completed will be worked by improved recording instruments with mechanical transmission of message.

The proposed amount of capital is £450,000, the tariff £3 10s. for a message to India, which, reduced by the royalties and the amounts to be paid out, will give a profit of £1 3s. per message.

The principal advantages of the proposed line are—the expenditure will be moderate—the security of the line guaranteed by conventions—the working of the line will be in the hands of the company, and of the Indian Government, giving a through communication, ensuring the greatest promptitude, and freedom from error.

The lines are to be completed within a twelvemonth, and it is proposed that they should, in the interest of the company, be constructed by Messrs. Siemens and Halcke, who, having constructed important lines in Russia, have a large staff of engineers and assistants at their command, who are thoroughly conversant with the work, and with the difficulties of language, habits, and climate, which will have to be encountered, and are, consequently, eminently qualified for the work.

This scheme is the one above all others which appears to meet the requirements of our Indian communications—the freedom from outward control—the message passing almost entirely under the hands of one administration. These are what we want to preserve a message intact and intelligible, so that the receiver may understand what is required; and believing that this scheme is eminently suited to meet our necessities, we bring it before our readers, believing that they with us will wish it every success.

Parliamentary Notes.

THE House of Commons re-assembled yesterday week after the Christmas recess, and on Friday, amongst its first deliberations, came the question of the West India mail stations as affected by the late disasters at St. Thomas's. The subject was entered upon by Mr. Kinnaird, who asked the Under Secretary of State for the Colonies whether the Royal Mail steamers were to continue running to St. Thomas's as the place for delivering and receiving the mails, or whether it was intended to adopt any English island for that purpose; and, of so, what island and harbour.

Mr. Adderley said the West India mails were not to continue to run to St. Thomas's, but one of the English islands would be selected for a new station. In deciding what this is to be, several points must be taken into consideration—the best port to which the steamers can run, the best time of running, and the capacity and suitableness of the several harbours which the different islands offer. The matter is under consideration, but no decision has yet been arrived at.

The dangerous state of the Nuneaton station and level crossing on the Trent Valley Railway were referred to by Mr. Newdegate, who asked the Vice-President of the Board of Trade whether his attention had been directed thereto, as well as to the fatal accidents which have recently occurred

Digitized by Google

there; and whether he would have any objection to lay upon the table of the House two reports of Colonel Yolland to the Board of Trade on the subject.

Mr. Cave said attention had been directed to the condition of the station, and, in consequence of the fatal accidents which had taken place at it, an inspector had been directed to report upon its condition. A copy of the report made had been sent to the directors, which was all the Board of Trade could do in such matters, and it would shortly be printed in the returns of railway accidents presented to Parliament. He should move that the report be referred to the select committee on the London and North-Western Railway.

In the House of Lords on Monday, Lord Airlie asked the Under Secretary for War whether any steps had been taken to carry out the recommendations of the Defence Committee in 1860. In the course of his observations his lordship entered into the comparative merits of turret as against broadside armour-ships, pointing out that of the whole armoured fleet we possessed hardly any two were alike either in armour or armament, size or draught of water. He deemed it the duty of the Government to have two distinct classes of vessels,—one as seagoing cruisers, and another class of enormous strength for coast and harbour duty only. It was useless to say that vessels of the latter class could be built as soon as wanted. He doubted if this was true in fact, and, even if it was true, and they could be so built, our sudden hurry would only leave us, as we were left in the Crimean war, to the high charges and bad work of the private contractors.

The Earl of Longford said it was true that the Defence Commission of 1860 did recommend the construction of a system of floating vessels for the purpose of harbour and coast defence, and they also indicated several rivers and harbours in which such vessels might with advantage be placed. The estimate of the Commission, including £1,000,000 specially devoted to those floating batteries, was £11,850,000. When the Government reduced that vote to a sum of £7,000,000, they excluded entirely the £1,000,000 for harbour defences. He believed it had been hoped that these defences might be gradually provided out of the ordinary Navy Estimates annually voted by Parliament; but it very soon became apparent that the hope was futile. Year after year it had been found that there was no surplus applicable to such a purpose. The members of the Defence Commission, who still turned their attention to such subjects, entertained the same opinion that they formerly did as to the great importance of floating batteries. But he feared that no immediate prospect existed of their construction being proceeded with unless Parliament consented to make some special appriation of moneys to this purpose, a course of which at present there did not seem to be any indication.

The East London Museum Site Bill was reported to the House with amendments. Whilst it was passing through committee Lord Redesdale explained that his opposition on a former occasion had been directed, not against the provisions of the bill itself, but against the want of sufficient notice with regard to the lands proposed to be taken or affected. The interval which had elapsed since last December had afforded ample time for residents in the locality to make themselves acquainted with the character of the proposals contained in the bill; but it was right that these should be also understood by the public at large. In establishing, as was contemplated, a museum for the east end of London, at the national expense, they were laying, he feared, the foundation of claims to have similar institutions established at the national cost, not only in other parts of the metropolis, but in all the great towns of the kingdom as well. For his own part, he could not see why Lambeth had not as good a claim to a museum as Bethnal-green, and Dublin, he believed, was already petitioning with this object in view. It might be quite right to establish this institution, but the precedent would certainly prove inconvenient. Very good, Lord Redesdale, but let us hope that the convenience of the museum will outweigh the inconvenience of the precedent.

As some of our readers may have forgotten the object of this bill, we may explain that it is to provide out of the public treasury a sum of money for the erection of a museum in Bethnal-green upon a piece of ground which has been purchased by means of subscriptions for the purposes of a museum. The erection of this museum is much desired by people in the east of London, and the bill is the fulfilment of the promise made by the late Government on this subject. It is understood that this is a special case, and there is no intention on the part of the Government to build any other local museums.

In the House of Commons on Monday, that dangerous point Daunt's Rock was brought forward by Mr. Maguire as a matter needing immediate attention. The hon. member asked the Vice-President of the Board of Trade if the Government had had under their consideration the danger to the naval as well as mercantile interests caused by the existence of this rock, and whether, after the late accident to one of her Majesty's ships, occasioned by the frame of the "City of New York" still lying on the rock, it was proposed to place a lighthouse on the rock or to effect its removal by blasting; or if he would say what were the intentions of the Government with respect to an admitted source of constant apprehension.

We are glad to find from Mr. Cave's reply that the subject has not only been considered, but that action has been taken upon it. Mr. Cave explained that in 1864 the Irish Lights Commissioners changed the light on Roche's Point to a revolving light, which threw a white light on the rock, and also placed a bell-boat there. That expense was paid out of the Mercantile Marine Fund. With reference to placing a lighthouse on the rock itself, it was one of those cases in which the light would affect the local trade, and it would be unfair to settle the expense of it on the whole mercantile marine. Captain Shadwell's report showed that the danger had been very much exaggerated, as from 1859 to 1866 only one casualty had occurred on those rocks. It was true that since that time the "City of New York" had been wrecked there, and that the rock had been touched by the "Research," and that the "Chicago" was wrecked several miles from it. The circumstances would not justify the Irish Light Commissioners in fixing the charge of any light on Cork, but if the trade was willing to defray the expense the commissioners would have no difficulty in placing one there. A proposition had lately been made for blasting the rock, and it was now under the consideration of the Admiralty and the Board of Trade. We should say, blast away, and get rid of the pest, by all means.

The Peninsular and Oriental Company's steamers having ceased to touch at Malta, the Under Secretary of State for the Colonies was asked by Sir G. Bowyer what steps the Government were prepared to adopt for the conveyance of letters to that island.

Mr. E. Egerton stated that by the new arrangement of passing through the Straits of Messina, instead of stopping at Malta, the transit of the mails between Marseilles and Alexandria would be accelerated by twelve hours. Other mails would still be conveyed to Malta by the Peninsular and Oriental Company, but what substitute would be given to Malta for the mail between that island and Alexandria was still under the consideration of the Government.

INSTITUTION OF CIVIL ENGINEERS.

AT a meeting of the Institution of Civil Engineers, held February 18, C. H. Gregory, Esq., president, in the chair, the paper read was on the supporting power of piles; and on the pneumatic process for driving iron columns, as practised in America, by Mr. W. J. M'Alpine, M. Inst. C.E. (of New York).

The first part of this communication related principally to the experience gained in driving 6,539 piles an average depth of 32ft., for the foundation of the Government graving dock at Brooklyn, N.Y., when the support was mainly derived from the adhesion of the material into which the piles were driven, and slightly from their sectional area. The piles were in rows 2½ft. apart, and at transverse distances of 3ft., all from centre to centre; intermediate piles of tough second-growth oak being frequently employed. The main piles were chiefly round spruce spars, very straight, from 25ft. to 45ft. long, and not less than 7in. in diameter at the smaller end, and on an average 14in. in diameter at the larger end. From a record kept during the progress of the work, it was ascertained that it took two and one-third blows to drive each foot of pile, and that the distance moved uniformly diminished from the first to the last blow, ranging from 8in. at the beginning to no movement at the end, the average distance moved by the last five blows being 1in. A considerable number of the piles were driven by a Nasmyth steam piling machine, with a ram of 3 tons, and a stroke, or fall, of 3ft., and making from sixty to eighty strokes per minute. The other machines were generally operated by steam power, giving an average of a blow per minute; but occasionally the hammers were hoisted by manual and horse power. The rams in the latter machines were of cast iron, swelled out at the bottom to concentrate the weight at that point, and weighed about 2,200lb. each, though were some were used of 1,500lb.; the fall being 30ft. It was observed that the heaviest ram, when striking blows of the same effect as lighter ones, did the least injury either to the head of the pile or to the protecting iron ring, and this injury was still less with the Nasmyth hammer. It was also found that no advantage was gained by the fall of the ram being more than 40ft., as the friction on the ways then prevented any increased velocity to the ram when falling from a greater height. With the Nasmyth hammer piles were driven 35ft. in 7min., while with the other machines similar piles required one hour or more to drive them the same distance.

Experiments were made at different times to ascertain the weight which the piles would sustain. For this purpose a long lever of oak timber was employed, with which a number of the foundation and coffer-dam piles of nearly the same size, and driven under exactly similar conditions, were withdrawn. It was thus ascertained that a weight of 125 tons was required to move a pile, driven 33ft. into the earth, to the point of ultimate resistance, with a ram weighing one ton, and falling 30ft. at the last blow. These trial piles averaged 12in. in diameter in the middle. From a number of other experiments, it was believed that the extreme supporting power of the pile, due to its frictional surface, was 100 tons, or one ton per superficial foot of the area of its circumference. From an analysis of the experiments, the following general laws seem to have prevailed in these cases:—1st. That the effect of lengthening the fall of the ram was to increase the sustaining power of the pile in the ratio of the square root of the fall. 2nd. That by adding to the weight of the ram, the sustaining power of the pile was increased by 0·7 to 0·9 of the amount due to the ratio of the augmented weight of the ram. 3rd. That a pile driven by a ram weighing one ton, and falling 30ft., would sustain an extreme weight of 100 tons. The formula based upon these data, as applicable to rams weighing from 1,000lb. to 3,000lb., falling from 20ft. to 30ft., was $X = 80\ (W + 0{\cdot}228\sqrt{F} - 1)$, in which X was the supporting power of a pile driven by the ram W, falling a distance F; X and W being in tons, and F in feet. The author was of opinion that under the most favourable circumstances, the pile should not be loaded with more than one-third of the result given by this formula; and when there was any danger of a future disturbance of the material around the pile, or when there was any vibration in the structure which might be communicated to the piles, the load imposed should not exceed one-tenth. The bearing support due to the sectional area of the pile had not been considered in the preceding inquiry; but numerous experiments had been made, which gave results of from five tons to ten tons per square foot.

The island occupied by the city of New York was separated from the mainland by a navigable tidal estuary, called the Harlem River, and this was spanned by several bridges. In reconstructing the bridge forming the continuation of the Third Avenue, it was decided to make a pivot draw in the centre; and, with a view of creating the least possible obstruction to the current, the draw pier was composed of one central and ten circumscribing iron columns, each 6ft. in diameter and 50ft. in height, the water in the middle of the river being 20ft. deep. Careful experiments upon the supporting power derived from the frictional surface of these columns, when sunk from 20ft. to 30ft. in moderately fine material, had led the author to adopt a coefficient of half a ton per superficial foot of the exterior surface. These piles were sunk by the pneumatic process (both plenum and vacuum), and the method of sinking them was next described in minute detail, as well as the apparatus and means taken to ascertain their sustaining power. Although the lateral support, as determined by the experiments, in addition to that which would be derived from a base of 6ft. in diameter, showed that it would be ample for that place; yet, in view of subsequent operations, the importance of devising a method of increasing even the large base due to the size of the column offered advantages too great to be neglected, and various methods of accomplishing this result were proposed. The one adopted was as follows:—It had already been decided to fill the columns with concrete, and it

Digitized by Google

was naturally suggested to extend this masonry below the bottom as deep as men could work in the water, and also to undermine the adjacent earth, as far as practicable, and to extend the concrete into the space. This was done in sections of about 2ft. in width, and when the ring had been completed, it was found that the column was virtually extended, and that the water would readily sink under pressure to a level with the bottom of the concrete, so that the sand within it was easily removed, and the space filled with concrete to a depth generally of 4ft., or more. Contrary to statements occasionally made, it was found that the cement set with far greater rapidity under pneumatic pressure than in the ordinary atmosphere.

The experience gained, and the reflections resulting from the operations at the Harlem Bridge proved, among other things, the rapidity, facility, and economy of driving iron columns of large size, under favourable circumstances. The extracts from the author's journal showed that the last columns were driven from 16ft. to 20ft. in from three to six days, in sand and porous material, free from obstructions. The economy of this work was indicated by the small force employed at Harlem, which was twelve men, all told, including the engine drivers, stevedores, and foreman. Their aggregate wages, and the expense of fuel, did not exceed £6 per day. The cost of the plant was under £1,500. The metal in the column, if but 1¼in. thick, was quite sufficient, would have been in New York £13 per lineal foot of the column. It was remarked that at Harlem the officers and workmen experienced neither temporary nor permanent ill effects from a pressure of two and a-half atmospheres. It was believed that cylinder piles might be driven to great depths, through extraordinary obstacles, such as rocks, logs, and sunken vessels, without serious loss of time, or at much cost; and that they would penetrate quicksand, which was so troublesome by all other methods, with unusual facility. Again, the columns might be regulated in their descent, and be suddenly arrested at any precise point, at the will of the director, by means of a pneumatic reservoir. Thus, the descent was commenced at first slowly, the velocity gradually increasing until the movement became dangerous, when it was instantly stopped. In some cases the piles could be driven by the vacuum process alone, in all cases by the plenum, and sometimes both might be employed with advantage; and the driving could be further aided by the use of mechanical pressure or weight. The support which such columns derived from their exterior frictional surface in ordinary earth was, as previously stated, at least equal to half a ton per square foot, but in the finest earth it would amount to three tons. The support from the area of the bottom in shallow depths was from five tons to ten tons per square foot; and at the great depth to which these columns would be ordinarily sunk, it must be considerably more.

LONDON ASSOCIATION OF FOREMEN ENGINEERS.

PRESIDED over by Mr. Whitworth, and supported by Mr. Reed and Mr. Penn, the London Association of Foremen Engineers may congratulate themselves that at their annual dinner, on Saturday last, they possessed among the company the respective representatives of attack and defence. Over 250 members and guests assembled in one of the large banqueting rooms in the City Terminus Hotel of the South Eastern Railway, which afforded every facility and accommodation for the required purpose. Among the guests were Major Jocelyn, Messrs. Penn, Napier, Rennie, Robertson, S. Smiles, E. J. Reed, Chief Constructor of the Navy; Captain M'Neile, Mr. Chetwynd, of the Post-office; and Captain Shaw, of the Fire Brigade. The room itself is deserving of notice. Beautifully but chastely decorated, richly gilded, and embellished with the armorial bearings of the City of London, Dublin, Edinburgh, and several other important European and continental towns, it was illuminated by six of the new sun lights, appropriately so termed, as, from the absence of all flicker, unsteadiness, and colour—the distinguishing features of artificial light—the illuminating source produces the same description of uniform glow obtained from natural causes. The room is furnished with a couple of galleries at the ends, the lower of which was occupied by ladies, but unlike those attached to the interior of St. Stephen's, no envious screen hid the occupants from the eyes of the beholders.

Among the various topics discussed in the different speeches, the one more especially of interest at the present time to us as a nation, and peculiarly so to the members of the Association, was that embracing the question of foreign competition. Different views were entertained, and different opinions expressed by different speakers, some maintaining that our long-vaunted supremacy in the various branches of mechanical and industrial art was as potent as ever; others contending that it was lost irrevocably. In neither of these views do we altogether concur. That our former supremacy is on the wane is undeniable; that we no longer possess the monopoly once in our hands is incontrovertible, with the tangible evidence in our markets, our workshops, and buildings. Divesting ourselves of all narrow prejudices and selfish considerations, and regarding the question in a broad light, the course of events existing at present, and certain to ensue in future, is an inevitable result of the age of progress. It must not be forgotten that we have, so to speak, reached the end, and in common fairness we cannot deny to others the attainments of that goal to which we have long ago ourselves arrived. The real difficulty lies in the fact that while continental nations have acquired our knowledge, have become "learned in all the learning of the Egyptians," we have not acquired theirs, which they possessed even during the time when we esteemed them ignorant almost of everything. In a word, while we have no absolute reason for fearing the competition of other nations, provided we take the proper means to maintain our own position, at the same time the signs of the times are unmistakable, and cannot be slighted or disregarded without serious consequences resulting from a neglect so reckless and so injudicious. In responding for the Army and Navy, Mr. E. J. Reed made an able speech, and noticed the importance of a ship possessing the quality of high speed as well as the advantages of thick plating and heavy guns. The secretary's report was next read, containing an interesting statement of the numerical, social, and financial condition of the Association. As is usual upon all similar occasions, the chief toast was "Prosperity to the Association," which met with an excellent reply from the energetic chairman, Mr. Newton. Mr. Wood and Mr. Smiles responded for "The Scientific and General Press," and after a few more speeches and replies the company separated.

It appears from the fifteenth annual report of the Association that during the year eight ordinary and fifteen honorary members have been added to the list, the total now being ninety-eight ordinary and sixty-three honorary members. The funds show a balance in treasurer's hands slightly diminished, but which has, however, been made up by arrears of contributions since paid. The following is an abstract of the annual balance sheet:—Income: Honorary members' subscriptions, £26 5s.; nominations and entrance, £7 7s.; members' contributions, £158 7s. 9d.; ditto, ditto, to library fund, £22 16s. 6d.; interest on stock, £11 16s.; with income for January and February, 1868, £27 2s. 6d.; total income, £253 14s. 9d. Expenditure: Books and periodicals for library, £13 19s. 0½d.; cleaning book-case, removing, and rent for ditto, £4 17s. 6d.; printing, £25 2s. 6d.; postage, £6 3s.; stationery, £2 11s. 8d.; advertisements, £1 8s.; committee meetings, £7 6s. 4d.; representative at Leeds, Foreman Engineer's anniversary, £5 11s. 8d.; rent of room, £8 8s.; secretary's salary, £10; advance to Dinner Committee, £32 4s. 3d.; paid to unemployed members, £119; sundry expenses, 15s. 10d.; expenditure, January to February, £10 14s.; total expenditure, £248 0s. 11½d.; increase of funds to February, £5 13s. 9½d. The total ordinary funds invested in purchase of £400 Three per Cent. Consols, £364 4s. 9d.; in savings bank, £60; in treasurer's hands, £62; total value of funds, £486 4s. 9d. The committee look upon the year's balance sheet as a proof of the substantial basis upon which the society is founded; and it is gratifying to reflect that at such a time, when the ordinary income is stopped, this Society has provided a partial substitute, entailing neither loss of dignity nor injury to the most delicate feelings. The superannuation fund has been increased since the last report £110 1s. by subscriptions from the following gentlemen:—Messrs. J. and A. Blythe, £20; E. J. Reed, Esq., £10 10s.; S. W. Worssam, Esq., £10 10s.; Messrs. J. and G. Rennie, £10 10s.; Messrs. G. and C. Bowen, £10 10s.; Robert Mallet, Esq., C.E., £5 5; Major Palliser, £5 5s.; Messrs. Campbell and Johnson, £5 5s.; Joshua Field, Esq., £5 5s.; John Penn, jun., Esq., £5 5s.; Charles Barclay, Esq., £5; Messrs. John Brown and Company, £5 5s.; Messrs. Morton, Wilson, and Company, £2 2s.; Messrs. John J. Bagshaw and Company, £2 2s.; Messrs. Gravel, Ewing, and Company, £2 2s.; S. W. Worssam, jun., Esq., £2 2s.; Charles Manby, Esq., £1 1s.; Jabez James, Esq., £1 1s.; Alfred Moore, Esq. (Braby and Son), £1 1s. There has been no application yet made for the benefit of this fund, which is now assuming such proportions as give additional stability to the Society.

IMPROVED PHOTOGRAPHIC PROCESS.

BY the usual manner of producing photographic impressions when the invisible impression is formed in the camera, it is removed into a dark room, and at once developed or rendered visible by means of solutions or analogous ponderable agents. Mr. F. B. Gage, of St. Johnsbury, Vermont, U.S., under a recent British patent, employs, on the contrary, what may be termed a partial development in the camera by the aid of diffused light. The development is afterwards completed in the usual way, taking the precaution to reduce the strength of the developing fluid with water.

Mr. Gage takes a photographic impression in the usual manner, and then places some plain dark dead surface in front of the camera, the sensitive surface still remaining in the camera. He then removes the covering from the lens tube, and exposes the sensitive surface on which the impression has been formed to the light reflected from the dark surface, while the dark surface is kept in gentle motion, so as to prevent the sensitive surface from taking an impression of any wrinkles or other variations on the surface from which the light is reflected. The time of this exposure is varied according to the amount of light reflected and the effect it is desirable to produce. The usual amount of time occupied in this exposure will be from one-fourth to double the time employed in taking the invisible impression; but in some cases ft can be extended much beyond this time. For a dark dead surface Mr. Gage usually uses a piece of thick black woollen cloth about 18in. square attached by one edge to a stick about 2ft. long, which is held horizontally and gently moved in front of the camera with the left hand, while the lens tube is uncovered with the right hand. It is not absolutely essential that this dark surface be kept in motion, but it is safer. This exposure of the sensitive surface to the light reflected from a dark dead surface apparently leaves the lightest portions of the impression but little changed, while it effects a much greater change in the darkest portions of the same, and thus harmonizes and properly blends the two, giving to the whole an atmospheric effect never before realized in photographic impressions; it also renders it less difficult to obtain the necessary intensity in negatives.

This invention applies equally well and is operated in the same manner in taking positives or negatives in the camera, and it may be used without further instructions in producing any style of photographic pictures. It is necessary that the dead surface be suitably lighted, and the time of exposure proportioned to the result desired to be produced. The best results are produced when the dead surface is as strongly lighted as possible without sunlight, using a diaphragm to reduce the aperture of the lens to prevent the development being so rapid as to become unmanageable. Mr. Gage has produced excellent results with a silver bath of twenty grains of nitrate of silver to the ounce of water, being about one half the usual strength in use, the sensitizing of the collodion being proportionally reduced; it will effect a great saving of expense for this reason. The inventor believes his invention also removes the most important obstacle to the production of dry plate impressions by harmonizing the lights and shades, which have heretofore usually been hard and inartistic. Exposing the sensitive surface in the manner described before the impression is formed has less tendency to blend the lights and shades than when done afterwards; but it gives a different and peculiar tone to the impression, which in some cases is very desirable, especially in negatives.

When the object to be impressed is strongly lighted, accompanied with deep heavy shadows, it is advisable to illuminate in the manner described the sensitive surface both before and after the impression is formed. This is effected by moving the black cloth before the camera a short time before as well as after, and operating otherwise in the same manner as before described. Some good effect may be produced by admitting transmitted light upon the sensitive surface, or light reflected from yellow and even red and other coloured surfaces, either before or after, or both before and after the photographic impression has been formed. The reflection from a dark dead surface, however, is much to be preferred, and Mr. Gage states that he has found his method of operating perfectly convenient and practical for use.

A VERY severe easterly gale swept over Gibraltar on the 11th and 12th inst., during which several vessels were wrecked on the eastern beach, attended with much loss of life.

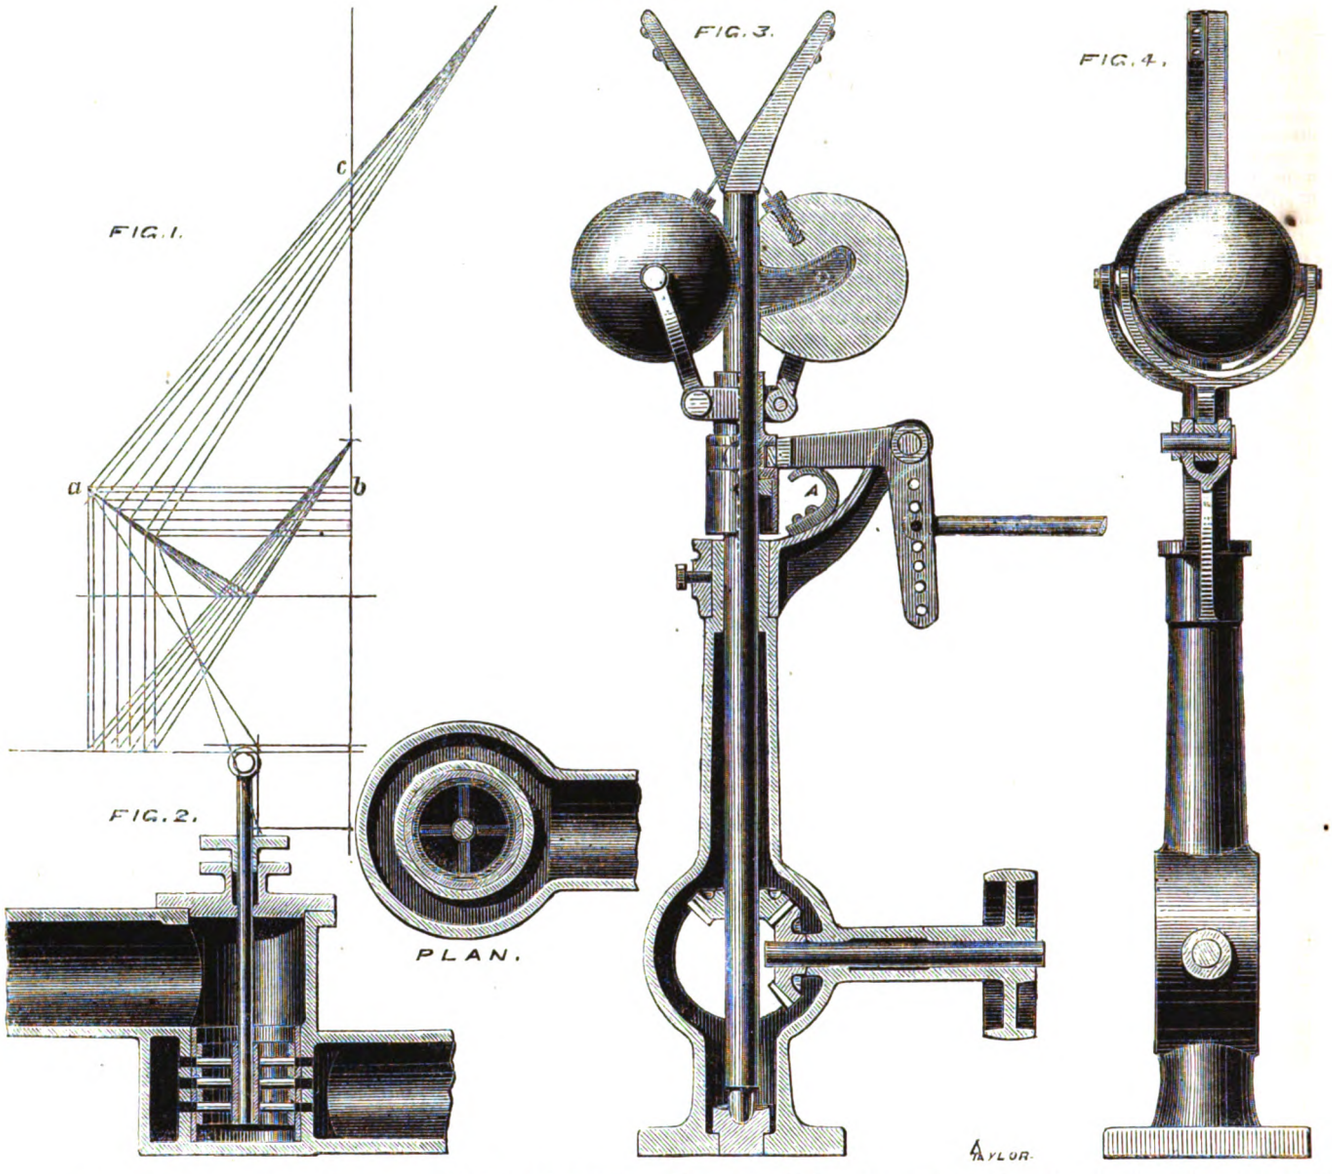
THE ISOCHRONAL GOVERNOR.

BY MR. HENRY DAVEY.



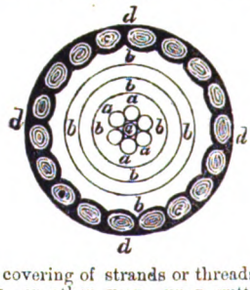
THE ISOCHRONAL GOVERNOR.

SINCE the time when James Watt invented the governor which bears his name, there has not been perhaps more time devoted towards perfecting any of his inventions than there has been towards producing a perfect governor which shall preserve a constant speed on the engine under extreme variations of load. It follows, from an abstract view of the problem, that if a governor is to depend on a change of velocity for its action, then no governor can absolutely preserve a constant speed, and all that can be done is to reduce that variation to which the engine must inevitably be subject to a minimum. With centrifugal governors, where the balls move in the arc of a circle, there exist two evils—the one is friction and the other is that every change of the position of the balls—that is to say, every new plane of rotation—demands an altered speed; this has long been recognized, and it has been well known that the arc of a parabola and not that of a circle is the curve in which the balls should move. Many governors have been constructed on what is termed the parabolic principle, but none appear to have been so practically carried out as the isochronal governor, which we illustrate above. Fig. 1 of our engraving is a diagram showing the mode of setting out the governor. Fig. 2 is a section of the throttle valve; figs. 3 and 4 are sectional and side elevations of the governor. This governor is the invention of Mr. H. Davey, of 9, Victoria Chambers, Westminster, and has for some time been in use. It possesses some peculiarities which we shall proceed to describe. It will be seen by reference to the engravings that the balls are suspended by means of a flexible leg of steel, from curved horns provided on the spindle, which causes them to move in a parabolic path. Fig. 1 represents the mode of setting out the governor, and it will be noticed that the legs are extremely short, and that the balls are made to move in a high portion of the parabola, the object of which is to make the centrifugal force represented by the line $a\ b$ as great as possible compared with the weight of the ball, or the line $b\ c$. The vertical height, or the line $b\ c$, determines the speed, and if the line be preserved constant then the speed will be constant also, and for a given velocity the balls will rest indifferently in any portion of their path, but with the Watt governor the vertical height varies constantly with every change of speed.

If a weight be made to move in a parabola without friction, the smallest change of velocity would cause it either to rise or fall as the case may be. The friction cannot be altogether dispensed with, but in the isochronal governor it is very small. It will readily be perceived that the momentum of the balls when rising or falling rapidly would cause them to move too far in either direction. To obviate this a small air cylinder is placed on the spindle, as shown in the engraving. Another feature of the invention consists in a means by which the engine is prevented from racing, in event of the governor gear breaking, or the belt accidentally falling off. It is effected in this way:—A spring shown at A is provided sufficiently powerful to keep out the balls when working, at, say, one quarter their proper speed, but not when at rest. A throttle valve, shown in fig. 2, is provided, and when the balls of the governor are just beyond the range of the spring, the valve is in the position represented in the engraving. The spring prevents the valve shutting when the engine is running slowly, but should the governor stop altogether, the valve is caused to close, or nearly so, as desired. The advantage of this arrangement is very great, especially with beam engines. We have before us now an instance in which a beam engine was reduced to a complete wreck, and the boilers completely emptied of water, from the breaking of the governor gear.

SUBMARINE TELEGRAPH CABLES.

THE object of the invention illustrated in the annexed cut is to give and preserve strength to electrical telegraphic conductors so as especially to adapt them to submarine purposes. The improvements are the patented invention of Mr. M. Gray, of Binswood House, Highbury Hill. They relate to



applying a covering of strands or threads of manilla, hemp, silk, or other yarn, upon gutta-percha or iudia-rubber, or other suitable insulating material enclosing the conducting wire, the yarns being coated with a protecting and preserving material. After applying a coating to the insulating conduct-

Digitized by Google

ing wires of the insulating material, strands of manilla, or of other yarn, saturated with tar, are applied, and then coated with gutta-percha and bitumen. A convenient way of carrying out these improvements is to pass the wires coated with gutta-percha through the opposite side of a chamber containing a heated compound of gutta-percha, by which it becomes coated, and simultaneously to pass the hemp (previously saturated) through other holes around but at some distance from that through which the coated wire enters, in order that these yarns may all become thoroughly coated with the gutta-percha and bitumen. The yarns and coated wires then pass out from this chamber through the same aperture or die so as to be compressed closely upon the insulated conductor, and the insulated conductor with its covering of yarn may then be passed together through a chamber for receiving a coating of insulating material.

The accompanying engraving represents a section of a series of conducting wires enclosed in the manner described. The circles *a* represent seven wires enclosed in four separate coatings *b* of gutta-percha compound, *c c* represent the strands of yarn, and *d* represents an outer coating to the whole. In some cases the whole is enclosed in coils of tape, which are laid on the coated conductors from a carrier which rotates round the coated conductor, as it travels forward.

TOUGHENING GOLD.

A PROCESS for toughening brittle gold bullion, refining of alloyed gold, whilst in a melted state, and separating therefrom any silver it may contain, forms the subject of an English patent granted to Mr. F. B. Miller, an assayer of Sydney, New South Wales. This is effected by means of chlorine gas (or hydrochloric acid gas, mixed with atmospheric air or oxygen) brought in contact with the alloyed gold when the metal is in a molten state. In this way the silver present and any baser metals which render the gold brittle are converted into chlorides whilst the gold remains in a purified and tough condition. Mr. Miller melts the gold in a good clay crucible (plumbago crucibles are not recommended); the pots known as "creusets de Paris," and manufactured by Payen, Rue Pierre Levee, Paris, are very suitable, and the sizes Nos. 12, 14, and 16, are most generally useful; they are suitable for refining charges of 100, 250, and 500 ounces respectively. The crucibles are prepared for use by dipping them into a strong and hot solution of borax, and afterwards drying them. The object of this is to render them less liable to absorb the melted chloride of silver. The crucible is heated in a furnance, and the gold is melted in the usual way with a small quantity of borax, about three-quarters per cent. The crucible has a closely fitting cover with a small hole bored through it, and when the metal is melted a fire clay tube of about 3-16ths of an inch internal diameter, is inserted through this hole, so as to dip into the molten gold down to the bottom of the pot. The upper end of this tube is connected by a vulcanized india-rubber pipe with a glass or stoneware vessel, in which chlorine is generated. The joints are tied round with wire, and the india-rubber pipe is protected from the direct radiation of the fire. The chlorine generator is fitted with a safety tube, six feet long, dipping at its lower end into the liquid in the generator, and the liquid stands in this tube to such a height as is equivalent to the pressure necessary to force the gas through the melted gold which is above the end of the fire clay tube. The current of gas through the metal is maintained for about three hours, and the metal may advantageously be agitated from time to time by stopping the flow of the gas for a moment by pinching the india-rubber pipe until the pressure increases, and then allowing the accumulated gas to pass suddenly. At the end of this operation the gold will be nearly pure, and the chloride of silver formed will be found floating on its surface, together with such other chlorides as may be formed and are not readily volatilized.

The contents of the crucible may be poured out altogether into moulds, so as to form ingots, and the chlorides are in this case detached from the surfaces of the ingots when they are cold. Or the metal is allowed to cool in the crucible until it sets, and the still liquid chlorides are then poured from its surface into a mould, so as to form a slab. The borax is in this operation retained in the crucible, and in this no difficulty will be found, as it is much less fluid than the chlorides. The crucible still containing the gold is at once replaced in the furnace until the purified gold is again melted, and it is then cast into ingots. The crucible if it is to be used again should not be allowed to cool, but be replaced in the furnace as soon as the charge is poured. The chloride of silver and other chlorides mixed therewith are reduced to the metallic state by one or other of the processes commonly employed for this purpose, but very conveniently the slab of chlorides may be placed between two flat pieces of wrought iron and immersed in water acidulated with sulphuric acid and there left for a day or so until the reduction is complete; the metal thus obtained is treated with nitric acid. The silver and other baser metals are dissolved, whilst some gold is left undissolved and is collected and remelted with other charges. The silver is precipitated from the solution with common salt, as chloride of silver, by again reducing which a pure silver may be obtained.

In this process hydrochloric acid gas mixed with atmospheric air or oxygen may be passed into the molten gold in place of chlorine. The operation is in all respects similar, except that a generator of hydrochloric acid gas is substituted for the chlorine generator, connected by means of a vulcanized india-rubber pipe with a gasholder, from which either common air or pure oxygen can be supplied under pressure regulated by a stop-cock. A mixture of hydrochloric acid gas with air or oxygen is thus obtained, which is passed through the molten gold in the manner described for the similar operation with chlorine. This mixture of hydrochloric acid gas with air or oxygen is, however, less efficient and convenient than chlorine, more especially when the object is the separation of the silver rather than the toughening of the gold by the removal of the baser metals it may contain. A very small quantity of the silver contained in the alloyed gold will be volatilized during the process; it may be recovered from time to time by treating the sweepings from the flues. A much larger but still a small quantity of the chloride of silver is taken up by the borax or is absorbed in the substance of the crucible; this is recovered by crushing the flux and the crucible when it is past further use, and treating them with weak ammonia which dissolves out the chloride of silver, and this is afterwards precipitated by the addition of an acid, and the silver is reduced from it. Or the powdered flux and crucible may be placed in a revolving barrel with scrap wrought iron and mercury with sufficient water to form a thin paste. By this means the silver is recovered as an amalgam, together with a little gold.

SULPHUR AND ITS REFINING.*

By Mr. Charles N. Ellis, F.C.S.

SULPHUR mines abound nearly all throughout Sicily, but, as the Sicilians have neither roads nor railways, those only are worked situate in the neighbourhood of a port, that is, in a radius of 40 miles, because the transport comes too dear. The transport is generally carried on with donkeys or mules as far as a high road, and then by small carts, which hold from 10 to 14 cwt., or direct to the port, the carriage of which costs from 1-8 tari per cantaro of 175 rottoli (= 1·75 cantaro ordinary.)

Sulphur mines are generally situated in the hills, being found and worked in the crudest manner possible. If, from indications of sulphurous water or other appearance, a man supposes there is sulphur, he begins to dig a hole. If he is successful in his search and finds sulphur, well and good; if not, he gives it up. Should he be successful, he hires a capomaestro (*i.e.*, a master who has apprentices under him, or young workmen), a sort of small contractor, with some five or seven lads, who digs out the hole, and the boys carry away the thrown-out material in small baskets on their shoulders (containing from 30lb. to 40lb.) The ore is dug out, and when a sufficient quantity is thus obtained a ring of stone is first built, from 20ft. to 50ft. in diameter and 10ft. high, with a slanting floor. This is then filled up with a very high cone with ore. It is then thatched with earth outside. This is termed a "calcarone." It is then set fire to at the top and burns downwards. When it has burnt for about a fortnight they then tap it at the bottom, and let the sulphur run out into forms made of wood—rinsed out with water (the water answering like buttering a pie-dish, &c.), and you can turn it out when cold without sticking to the mould—called "battate," of about one to two hundredweight each.

There are, of course, large mines, where seventy or one hundred capomaestri are employed with their boys.

If water is met with, a drain is either built under the mine (which is very expensive), or it is pumped out with drums, which is very inadequate, consequently most mines with water are given up.

Some mines there are with steam pumps, which have seldom done well, for the following reasons:—

1st. The English drivers were drunken fellows.

2nd. The proprietors would not sink shafts.

3rd. If there is the least thing wrong in the machinery, repairs cannot be done on the spot. If sent for repairs to ——, much delay is caused by the dilatoriness of the foundry officials, and when the things do arrive they do not fit. They have then, at last, to send to England, consequently nearly a year's time is lost.

But most of the mines are worked by people without means, who, of course, cannot afford to buy machinery, and, what is very extraordinary is, that the richest mines contain water. This water does not appear to rise from wells, springs, &c., but is chiefly caused by the heavy penetrating rains of winter.

It is but rarely that mines can be bought, as nearly all the land belongs to nobles, who reside in Palermo, and who let their mines at the rate of from 15 to 45 per cent. of the produce.

Thus, as things are carried on, it requires but little capital; but, with a good capital, I am convinced a very good business would be done, so as to net not 10 to 20 per cent. on the outlay, but a good deal more.

Let us suppose a man with a capital of £100 takes a mine, and engages some capomaestri with their boys; he pays them, perhaps, once a month, or more seldom, and according to the number of "casse" of ore they have worked out; he then at once sells sulphur for delivery, either at once, one month, three, six, nine, or twelve months, and receives perhaps one-third, half, or the whole price, but of course suffers heavily, for the merchants won't lay out their money for nothing. The sulphur is then deliverable at the port, where there are stores which receive it, where the carriage is advanced, for which he pays again from 2 to 2½ per cent. in sulphur.

This is a brief sketch of how the Sicilians carry on sulphur mining. As a profitable investment, I should recommend boring to ascertain where the greatest quantity of ore was to be found—if a mine not already in work be obtained. A company with a capital of £20,000, with part paid up (or private firms for their own consumption in England, with overplus for sale), would be amply sufficient, at all events for a commencement. The great thing would be to have pumps that do not easily get out of order. There should be a blacksmith's forge, with a fitter, a man who thoroughly understands the working of pumps, and could do all repairs when out of order, and a general manager who has a good general practical knowledge. Steam engines of 10-horse power, or even less, where the work cannot be done by mules, I should think would be the best. The engines should be of such a kind that they can be easily transported and put together; no part should weigh more than 3¼ cwt. or thereabouts, as perhaps they would have to be transported to their destination on the backs of mules, depending entirely upon the situation of the mine; these things managed, all the rest is easy.

There are hundreds of mines ready for work, and there would certainly be a good dividend the end of the first year. Here I should observe (Girgenti) that the mining goes on all the year round, but the burning only from the beginning of June, when the harvest in the neighbourhood is over, to the end of October, when the sowing season commences, else one has to pay damages. A mine with water would be let at from 15 to 25 per cent. for a number of years. "Calcarone" are generally made of from 200 to 600 "casse" of ore, and a "casse" weighs (more or less) about six tons, and produces from 12cwt. to 16cwt. of sulphur; the fusion of such a calcarone lasts about two months.

There are, of course, preliminary expenses, such as finding veins, building calcarone, making of passages, or sinking shafts, engines, coal, &c. For other charges the following may be taken.

Say a mine, producing 25,000 cantari (175lb. per cantaro)—about 1,154 tons, at 13 cantari to the ton, would require for administration as follows:—

1 Administrator, paid at the rate per ann.	...	£75
1 Capomaestro (species of mining engineer)	...	40
1 Accountant		40
2 Measurers, each £30 to £35		65
1 Policeman		25
Total	...	£245

The miners with their boys are paid according to the situation or richness of the mine, at the rate of 45 to 60 tari per casse (or even less, a taro = 4d.), but this includes all charges, as follows:—

Administration	...	£240
2,500 casse of ore at 50 tari	...	2,083
I assume for general expenses, such as finding, building calcarone, &c.		500
		£2,823

From 25,000 cantari deduct 25 per cent. for proprietor; this would leave 18,750 cantari, or worth 9 tari per centaro; at the mines for best seconds, about 18 tari.

But, of course, one must make allowances for many other expenses, and for accidents, such as part of the mine falling in, &c., calculations differing at every mine, as also the qualities. There are, however, a mine or two which might be got close to the sea-side, which would produce 50,000 cantari of best seconds, where the sulphur could be embarked without charges, and might be got by good parties for 22 per cent. for nine or eighteen years, and no damage could be done in the neighbourhood. No doubt they would require pumps, but in other respects they are in working order. I have been informed that close to Girgenti there is a coal-mine, or rather a mine of schist, containing a kind of tar (it smells like petroleum), which might be made useful, with knowledge and means; it is not worked, and is close by a sulphur mine, which has water, and might be had cheap.

* "Society of Arts Journal."

In the year 1841 the quantity of tobacco cleared for consumption in the United Kingdom amounted to 13¾oz. per head of population. In the year 1851 the amount had increased to 1lb. 3¼oz. per head of population; and in the year 1865, to 1lb. 5oz. So greatly is the habit of smoking tobacco extending in this country.

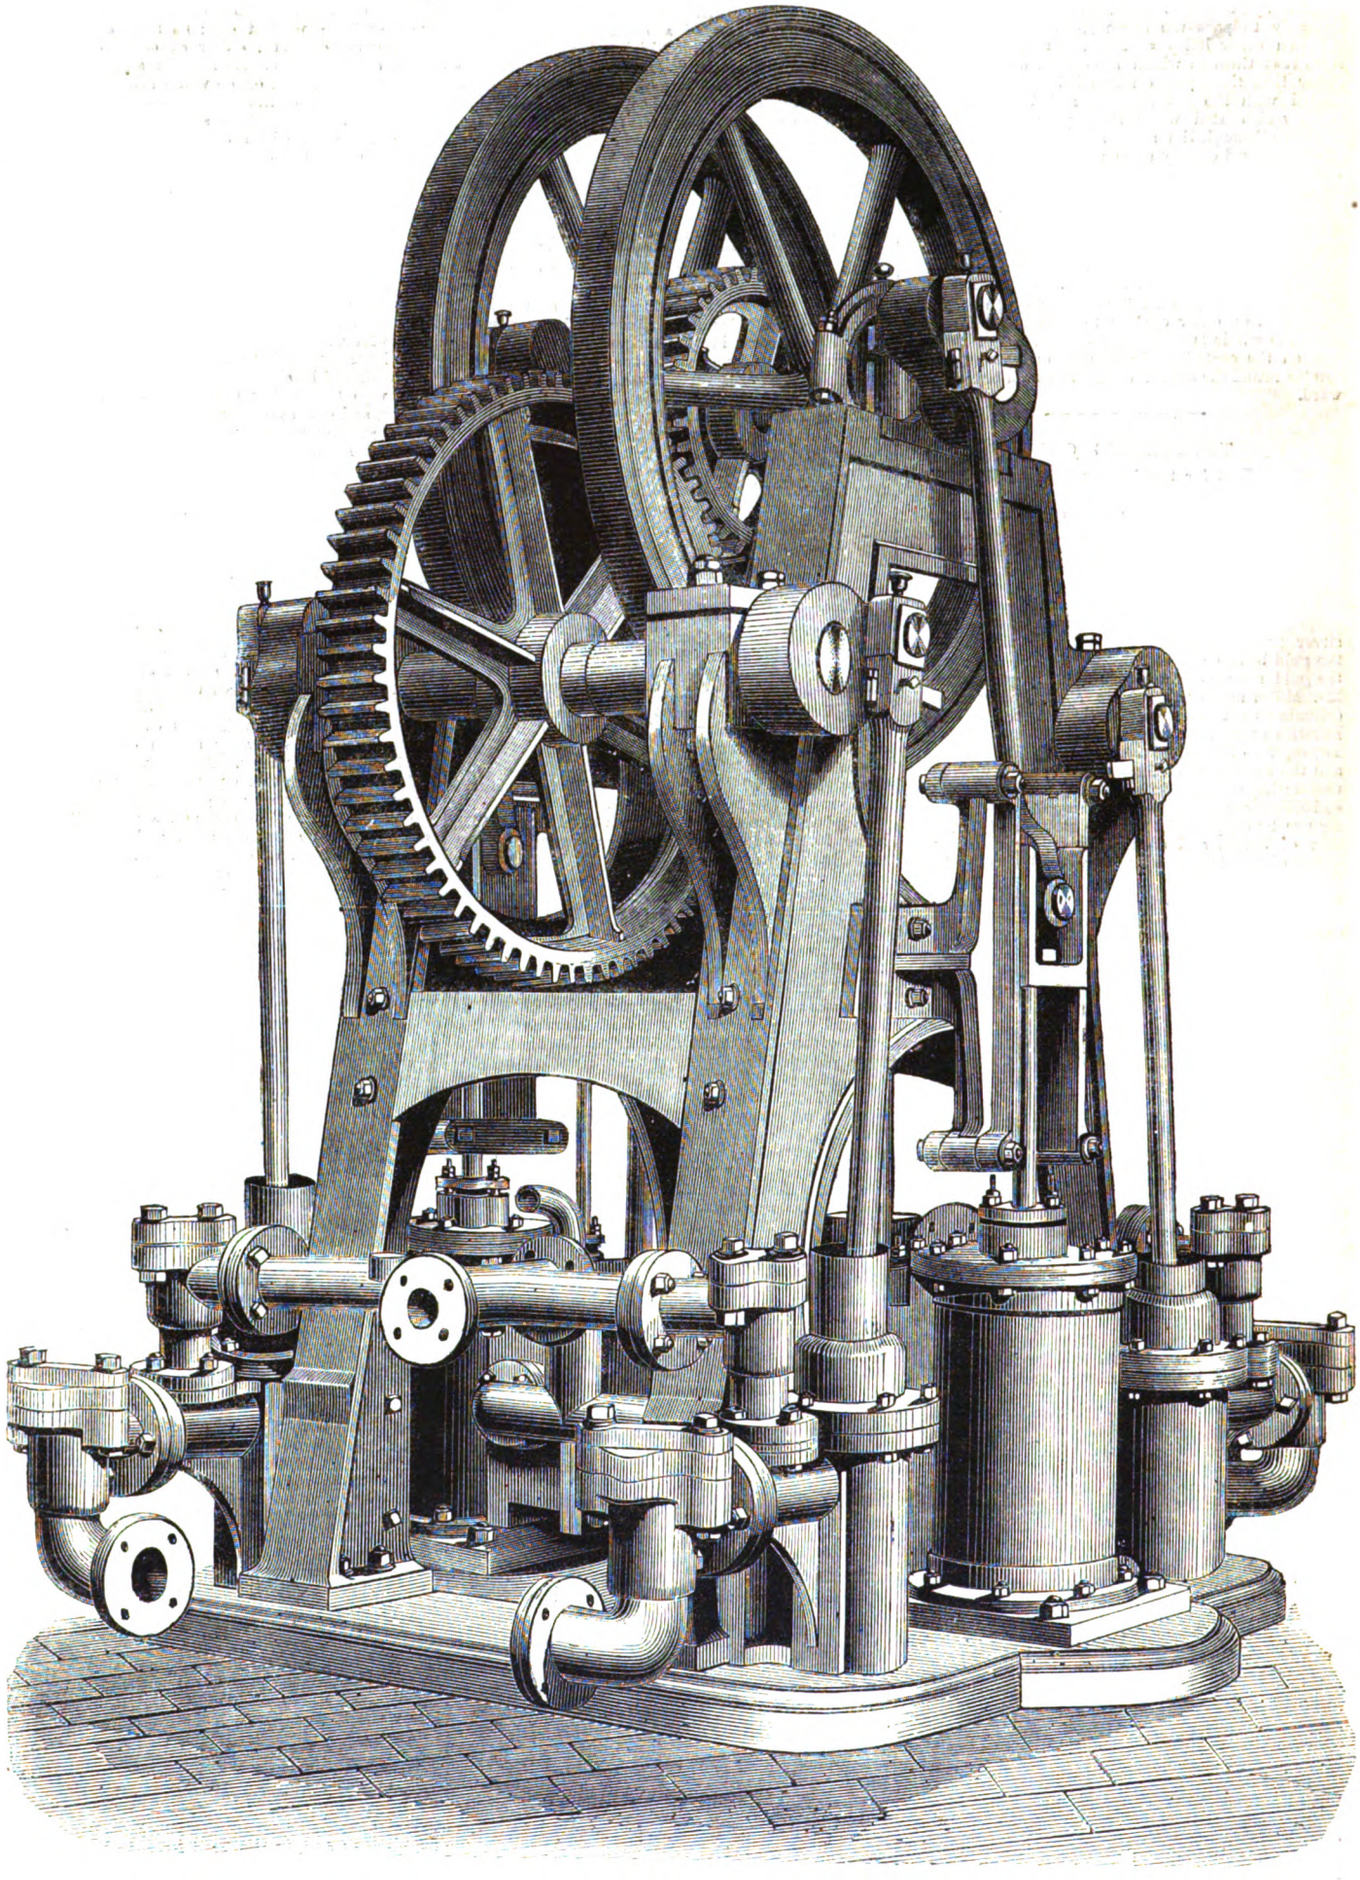
COMBINED ENGINES AND PUMPS FOR THE WEARDALE AND SHILDON WATER WORKS.

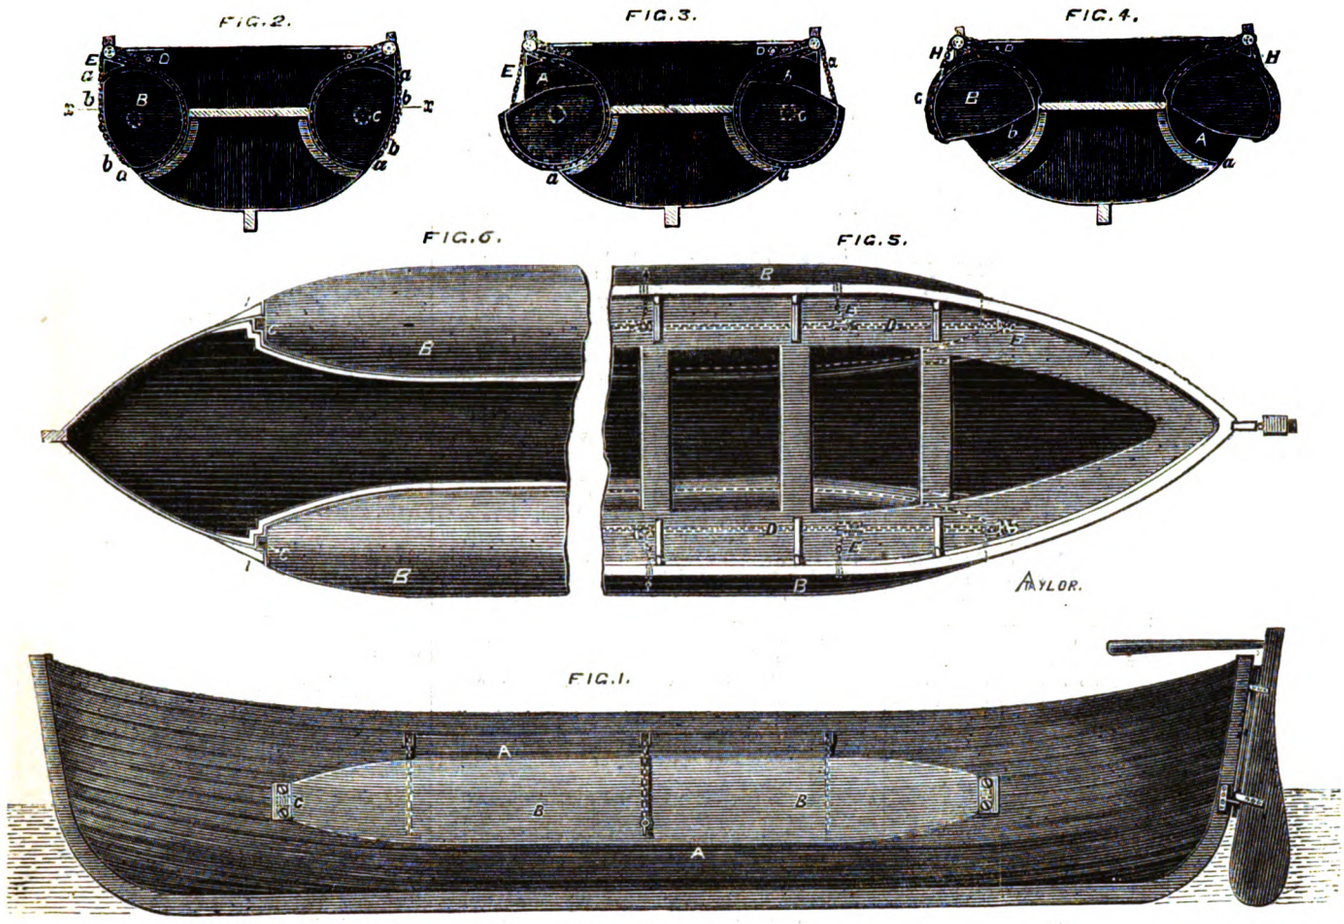
BY MESSRS. CARRETT AND MARSHALL, LEEDS..



Digitized by Google

THE INSUBMERSIBLE LIFEBOAT.

BY MR. H. W. WITHERS.



ENGINES FOR THE WEARDALE AND SHILDON WATERWORKS.

OUR page engraving this week shows a combined pair of engines and four pumps, of 30-horse power, now in course of erection at the Weardale and Shildon Waterworks, at Shildon. This engine was designed and manufactured by Messrs. Carrett and Marshall, of Leeds, upon a principle they are now largely carrying out in practice. This principle, as applied to a horizontal engine, was illustrated by us in the MECHANICS' MAGAZINE for November 15, 1867, when we fully described it, so that we need not now more fully refer to its details. The engine in question, as will be perceived from the engraving, is self contained on one bed plate, and can be used independently of any foundation. The steam cylinders are 14in. diameter with a 20-inch stroke. The four ram pumps are 7½in. diameter and 12-inch stroke. They are of simple construction, with brass rams guided the whole length of the working barrel. These are packed with hydraulic leathers which are easy of access for renewal. This engine is designed to force a continuous stream of water at 500lb. pressure to any required distance. At the Shildon Waterworks this engine will have to force 35,000 gallons 470ft. high in twenty-four hours. Messrs. Carrett and Marshall are now constructing another of these engines for the same company. Besides waterworks, these engines have been successfully applied to the working of hydraulic coal cutters, hauling engines, and dip level pumps in mines.

THE INSUBMERSIBLE LIFEBOAT.

THE chief characteristics of the boat which forms the subject of the accompanying illustration are its great extra buoyancy and lateral stability, which are obtained without too great a diminution of its internal capacity. It is the patented invention of Mr. H. W. Withers, of New Cross, and although calculated chiefly for ship service—being a great improvement upon the present lifeboats carried by emigrant ships, troop ships, and steamers—will be found invaluable if used for other lifeboats for land service. The invention consists in forming externally in each side of the boat a longitudinal recess of curved form, and in fitting in each recess a hollow cylindrical structure, or a corresponding solid structure of cork or other sufficiently buoyant material. When the boat is stowed away these structures fit into the recesses and then form part of the ordinary contour of the boat, but when the boat is required for use and lowered into the water, and more carrying power is required, they are turned upon their centres so as to extend out from the sides of the boat and thus give additional bearing or surface, whereby the buoyancy and lateral stability of the boat are greatly increased. The structures are narrowed towards their ends, so as not to interfere with the way of the boat.

In our engraving fig. 1 is a side view, and fig. 2 a mid-ship section of a boat constructed according to Mr. Withers' invention, the structures being in the position in which they form part of the ordinary contour of the boat; A A are the longitudinal recesses formed externally in the sides of the boat; the transverse section of these recesses forms at all parts a segment or portion of a circle *a a*. B B are the hollow structures of iron or other material fitted in the recesses A A; in the position shown in fig. 1 and fig. 2, the inner faces *a a* of these structures correspond with the curve of the recesses A A, while their outer faces *b b* correspond with and form part of the ordinary contour of the boat, as shown. The hollow structures B B are centred on pivots at C C. When the boat is required for use, and great buoyancy and lateral stability are necessary, the hollow structures are turned upon these pivots, so as to extend out from the sides of the boat, either as shown in the midship section fig. 3, or in the similar section fig. 4. In the former case the portion of the structures which was outside is brought uppermost, while, in the latter case, it is brought lowermost. Fig. 5 is a top view, and fig. 6 is a horizontal section through the line *x x* of fig. 2, showing the narrowing or tapering of the structures B B towards their ends, so as not to interfere with the way of the boat.

Mr. Withers sometimes employs chocks I, forming continuations of the bow ends of the structures and running them off, as it were, to a point; these chocks may be made to ship and unship as required. To move the hollow structures B B on their centres, chains E E are fitted thereto, and are carried to the inside of the boat, and led round a bar D, shown in dotted lines in fig. 5. This bar is connected by gearing to a vertical bar F, which may be turned by a handle. In the engraving, three chains E are shown on each side of the boat, two of which are passed partly round and connected to one side of the structure B, and the other is passed partly round in the reverse direction, and connected to the other side of tho structure. Sometimes, instead of or in addition to the pivots C C, the structures B B are supported by means of curved bars G G, as shown in fig. 4, attached to the structures B B, and moving in guide eyes H H, fitted in the recess A A of the boat. The eyes H H, with the turned-in ends of the bars G G, also act as stops to prevent the structures being moved round too far. The bars G G may be fitted in the recesses A A, and the eyes H H secured to the structures B B. In some cases, Mr. Withers divides and strengthens the structures by partitions, so that if they are forced in or damaged at one part they will still retain a considerable portion of their buoyancy. Any convenient arrangement or appliance may be adopted to prevent the water entering the spaces above or below the structures B B, when moved on their centres. Although we have spoken chiefly of the structures B B as being hollow, they may be made solid, provided they be of cork or other sufficiently buoyant material. This invention will be found of great advantage in fishing boats, as by moving out the structure B at the side at which the nets are being drawn in, greater buoyancy is obtained at that side and additional safety thereby secured.

It will thus be seen that this boat has a large amount of buoyancy in such a position as to give the greatest lateral stability, rendering her powerful and safe, impossible to sink, and most unlikely to capsize. Besides these features, it combines the other qualities required in a lifeboat—roominess for large numbers of passengers and provisions, width to pull, double banked, stability to resist people moving and pressing down on one side, in rescuing men from the water, liveliness in a seaway, and power and stiffness under canvas. With a view to give extra buoyancy, the ordinary lifeboats are fitted with air cases running under the level of the thwarts, which can only be of service when the boat is full of water and the passengers in a perishing state; in Mr. Withers' boat the greater portion which remains in the other boats useless is removed to the outside of the boat and becomes exposed to the action of the water. Air cases inside boats, of course, do not give stability. In the event of the broadside of an ordinary boat being stove in she would be likely to sink, as the water would find its way into the boat, whereas Mr. Withers' cylinders, being fitted in

Digitized by Google

compartments, if stove in, the water would be confined to that spot only, the other parts retaining their buoyancy. Air cases, if built in the boat, are too often found out of order; in times of peril they are also difficult to repair. In the boat under notice these structures can be readily taken out and kept in order. The opinion of practical boatbuilders who have investigated Mr. Withers' system is that, from her roominess and power, a boat on this principle could leave a wreck with a large number of passengers and provisions without much fear of either capsizing or sinking, and there would be no difficulty in constructing such a boat. We believe this to be an invention so promising that it only requires bringing prominently before the Admiralty and the public in order to insure its adoption.

THE BRITISH HOROLOGICAL INSTITUTE.

THE last half-yearly meeting of the members of the Horological Institute took place at the close of last year, and we are glad to find from the report, which we lately received, that the number of members has increased since the previous meeting. It is also satisfactory to learn that the finances of the Institute are, considering the depressed condition of the trade, in a better state than could have been expected. An offer having been made by a gentleman to give lessons in geometry and its application to watchwork, the council have formed classes which are now in full operation. The council refer with deep regret to the loss the Institute has sustained in the death of their president, Valentine Knight, Esq., an event we recorded at the time it occurred. Certainly a gentleman more devoted to its interests it was impossible to have found, one more influential in effecting its progress could not have been desired. The Journal of the Institute, we are glad to see, continues to show an improved sale, one of the evidences of its usefulness to the trade. The labour, however, connected with its monthly preparation of literary and scientific matter is, the council regret to say, still performed by the able editor, Mr. B. Strachan, without remuneration. This state of things has so long continued that the council appeal to the members to aid them by introducing fresh members to the Institute, that the council may be able to offer some equivalent for such valuable service. In the meantime, we are glad to observe that a meeting has been set on foot to present Mr. Strachan with a testimonial. In editing the "Horological Journal," Mr. Strachan brings a large amount of mathematical knowledge to bear upon his work, and renders the journal a worthy exponent of the science of horology. We, therefore, trust that the members generally will follow the initiative taken by the council, and subscribe largely to the fund.

SOCIETY OF ENGINEERS.

(Continued from page 111).

THE PANAMA LINE.

THE Liberator, Simon Bolivar, President of the Republic of Colombia, gave a commission dated Bogota, the 29th of November, 1827, to Captains John Augustus Lloyd and Maurice Falmark, officers of engineers in the Colombian service, to survey this route. Captain (afterwards Colonel) Lloyd's observations were published in the "Philosophical Transactions," and in vol. i. of the "Journal of the Royal Geographical Society." In 1840, Mr. Wheelwright was commissioned, by the Directors of the Pacific Steam Navigation Company, to report upon the best means of opening a communication between the river Chagres and the Pacific; but his suggestions were not carried out.

In consequence of the representations made by M. Salomons, of Paris and Martinique, who obtained a privilege and concession, in 1836, and again in 1839, for constructing a canal by this route, and who was the promoter of the Franco-Grenadian Company, Louis Philippe and M. Guizot gave orders in September, 1843, to M. Napoleon Garella, to make a detailed survey of it. Garella, assisted by M. de Courtines, and other engineers, made a survey of the country under the most favourable circumstances, having had the assistance of a French vessel of war, and the support of Colonel Pineda, the Governor of Panama. On concluding it, he submitted a plan for a canal of dimensions sufficient for the transit of sailing vessels of 1,200 tons only. He proposed to make it 23ft. deep with locks 45ft. 6in. wide, and 218ft. between the aprons. Its width was to be sufficient to allow two vessels to pass freely, except at the summit, where there would be a tunnel. He proposed to make a cut from Navy Bay to the Chagres, to partially follow the river to the junction of the Trinidad with it, and to complete the remaining distance by a canal along the valleys of the Bernardino and Caimito to the Pacific terminus at the little bay of Vacat del Monte, about 2½ miles east of the river Chorrera, and 12½ miles west of Panama. The direction of the line was nearly south-east; and its length 47½ miles,* of which nearly 42 would require to be canalized. The lowest summit level found was the Col de Ahogayegua, 459ft.,† at which height a sufficient supply of water could not be obtained. It was only by means of open trenches 1·65ft. deep and 62½ miles in length that he could convey water to a level of 135ft. He therefore proposed to establish his summit level at 135ft. above high water of the Pacific, for a distance of 25,361ft., of which 17,750ft., or 3¼ miles, would require to be tunnelled. To this level he would rise by 18, and descend to the Pacific by 17 locks. The latter would be much crowded, as Ahogayegua‡ is only 8 miles from the Pacific. The tunnel was to have been of height sufficient to allow a vessel of 1,200 tons to traverse it with her lower masts standing. The canal would require 36 locks and 6 aqueducts. He estimated that the work could be done for 12 francs per cubic mètre, or 9s. per yard, and that the whole cost would be 105,455,442 francs 75 centimes. In this sum he included the tunnel, 5,350 mètres in length, which would cost 6,700 francs per mètre, or 35,845,000 francs, equal to £1,433,800. The construction of a pier or mole, 1,100 yards long, in Navy Bay, and the formation of an entrance basin in the bay of Vacat del Monte, would raise the expense to 125 millions of francs, or about five millions sterling. Garella made another estimate for a canal of smaller size, with locks 170ft. long, 38ft. wide, and 20ft. of water, capable of admitting vessels of 600 tons, which amounted to about £3,600,000.

The necessity of excavating a tunnel 3¼ miles in length, and the great number of locks required, were considered objectionable by the promoters; but the principal reasons which decided them to abandon the project were the insecurity of the anchorage on either coast, and the insurmountable obstacle presented by the sandbank which extends from the shores of Panama Bay three miles out, and is high and dry at low water, except in the tortuous and impracticable channel of the Rio Grande. Vessels of even less than 300 tons have to lie two miles to seaward of Panama, and are obliged to discharge their cargoes into flat-bottomed boats. If it were even possible to cut through this sandbank, a single high tide might fill up the channel with sand again. Though the anchorage is generally safe, it has happened that all the ships lying there have been stranded; and all the vessels in Panama Bay were wrecked in a gale that blew with almost the force of a hurricane for twelve hours on the 17th of October, 1833. The houses at Chagres and Nicaragua were blown down by this gale. H.M.S. "Comus" quitted her anchorage at Chagres, when the barometer was observed to be falling rapidly, and so escaped.

Navy Bay is still more objectionable as an anchorage, being open to winds from N.E. to N.W., round by N., whilst hard northers are of frequent occurrence there. Great damage was caused by one on the 31st of December, 1854; and another which blew early in the morning of the 22nd of November, 1862, destroyed the wharves, drove the R.M.S. "Avon" ashore, and wrecked every vessel at anchor, except the American steamer "North Star," and the R.M.S. "Derwent," which left just in time. Although the notion of cutting a canal by this line has long since been given up, Garella's admirable work,§ in which a number of interesting hydraulic problems are solved, and minute calculations given, is a most valuable addition to our knowledge.

THE CHEPO LINE.

The line from the mouth of the Chepo or Bayano river, 24 miles east of Panama, to Mandinga or San Blas Bay, is the shortest between the two oceans. Mr. Wheelwright attempted to cross there in 1837, but was stopped by the Indians. In 1847, the late Mr. Evan Hopkins, M.E., who was employed by Gen. Mosquera, then President of New Granada, to survey the route, endeavoured to cross in company with Don José Marcellino Hurtado, of Panama, but they were driven back by the Indians, the chief of whom flogged a man who had accepted from them a present of a scarlet military coat. In 1849 the author visited the Chepo, but an examination of its entrance satisfied him that a canal there would be impracticable. More recently, Laurence Oliphant, Esq., ascended the river, and his observations were communicated in a paper read before the Royal Geographical Society, on the 24th of April, 1865. In 1864, a survey was made by Messrs. M'Dougal, Sweet, Forman, and Rude, at the expense of F. M. Kelley, Esq., of New York. The line taken was up the Chepo to the Mamoni, then along the valley of the latter to the Cordillera, and from its Pacific foot to the mouth of Mandinga river. The Chepo is a large river, navigable as far as Terable, a ruined fort, one mile above which the tide reaches. The total length of the line would be 30·030 miles. The lowest summit level is 1,500 feet. The length of tunnel required would be seven miles. The harbour on the Atlantic is safe, capacious, and deep, and the survey shows that the channel leading from the Chepo to Panama Bay has not less than 18ft. of water at mean low tide, whilst the ordinary rise of tide is 16ft.; but this result does not accord with the Admiralty chart. The latitude of Chepillo Island, off the mouth of the Chepo, was found to be 8deg. 59min. 40sec., and its longitude 79deg. 7min. 40sec. High tide in the San Blas Bay was 2½ft.

It is not likely that the Darien Indians would quietly give up their sovereignty over the Atlantic portion of this territory, since their largest villages and the residence of their oldest chief are on the shores of Mandinga Bay, on the cays and islets in which they strike turtle, which is their principal occupation. In 1848, Colonel Hughes, of the United States' Topographical Engineers, visited the bay in an American ship of war, and endeavoured to obtain permission to cross the isthmus, but received a decided refusal. The route by which Lionel Wafer crossed the Isthmus of Darien, in 1681, was from the mouth of Congo river, in the Gulf of San Miguel to the mouth of the Concepcion, 30 miles east of the Mandinga. His account of the stupendous mountains he crossed between the Chepo and the Atlantic shows the impossibility of making a canal communication in that direction. The Chepo route follows the boundary line between the Isthmus of Panama and the Isthmus of Darien, which corresponds nearly to the meridian of 79deg. W.

THE ATRATO LINES.

At about 4deg. N. the Cordillera of New Granada bifurcates, one branch continuing northwards close to the Pacific, the other, after diverging a little to the eastward, re-assuming a northerly direction, under the name of the Cordillera of Chocó, for of Antioquia, till it terminates on the eastern side of the Gulf of Urabà, or Darien. The two branches thus enclose a large oval space, reaching from about 4deg. to 8deg. N. latitude. This is divided into two unequal parts by spurs thrown out from either branch in 5deg. N., which separate the smaller and southern valley of the San Juan from the larger and northern valley of the Atrato. The Atrato valley is a great alluvial plain, separated from the Pacific by the Cordillera of the coast, and from the valley of the Cauca and the province of Antioquia by the Cordillera of Chocò. It lies between the parallels of 5deg. 26min. and 8deg. 5min. N. It has a width of from 100 to 150 miles, a length of 159 miles, and an area of 21,000 miles. Immediately under the surface of the plain is a stratum of firm clay and vegetable mould, overlying, at a depth varying from a few inches to several feet, the gold-bearing clay and gravel. This auriferous stratum, called cascalho, varies in thickness from 2 to 20 and even 50ft. Branches and roots of trees abound in it, as also beds of leaves carbonized and resembling compact peat; and coal is said to exist in the Antioquian range. Through the valley flows the Atrato, almost due north. It is formed by the confluence of the Quito and the Atrato, and in its course receives the Bebarà Murri, Pato, Andagueda, Napipi, Murindo, Sucio, Pavarando, Truando, Salaqui, Cacarica, Tumarador, and many other tributaries; and, after a course of 300 miles (following its sinuosities) empties itself by thirteen bocas or mouths into the Bay of Candelaria in the Gulf of Darien.

The great quantity of water in this river is owing to the fact that the clouds seldom pass over the Cordillera to the Pacific, but discharge themselves into the valley, thus maintaining an ample supply through all seasons of the year. Its banks are nowhere high, being principally levées or embankments formed from the sedimentary depo-

* Bief de Partage, 7,730 metres; Versant Sud, 13,450; Versant Nord, 55,360 = 76,540 metres.

† A much lower level was found afterwards, that of the Panama Railroad being only 287ft.; and a few years ago a summit level of only about 150ft. was found; thus substantiating the accuracy of the assertion made years before by Alphonse Morel.

‡ This Spanish word means "drown (or choke) the mare."

NEW MUZZLE LOADING FIELD GUN.

its brought down by the current and precipitated. In some places the surface of the water is above the land on either side. From its mouth to its source no rock has been discovered in the river, nor stone of any kind, except small detached pebbles, in any part of the valley. In the lower part of its course there is a level expanse thickly covered with mangroves (Avicennia nitida and Rhizophora mangle), and inundated at high water. It may, indeed, be said that there is no shore for 60 miles above its mouth. Further inland are some gentle, rounded elevations, and beyond them is the Cordillera on each side. At Quibdò,* the capital of the province of Chocò, at the elevation of 75ft. above the level of the sea, from which it is 220 miles distant, its width is from 800 to 900ft., and its average depth 9ft.; but during floods it rises to 15 and even 25ft. The rate of fall from thence to the sea is only 3in. in a mile. Below Quibdò it increases in width and depth, and is an immense river down to the point where it divides into the canos, or channels. About 15 miles above its mouth, it winds round the base of the Lomitas, or hills of Cacarica, which are spurs of the Sierra de Maly, of Darien, that approach its left bank; and thereabouts are the river and lagoon of Cacarica, from which there may be an Indian trail across the Cordillera into Darien. Immediately below the Cacarica mouth, but on the opposite or east bank, there is a hill, named Loma de Pulgas,† which is formed by an accumulation of mud. Lower down, on the east bank also, there is another, 140ft. high, called Loma de Tumarador, at the mouth of the Tumarador river, just above the Delta.

About 8 miles in a direct line from Candelaria Bay the Atrato divides into two channels; these, dividing and sub-dividing, its waters find their way to the gulf through a submerged delta, densely covered with a tangled jungle of mangroves, between banks having no consistency and no soil visible. The canos, thirteen in number, are named from N.W. to S.E., Tarena, Candelaria, Pavas, Barbacoas, Coquito, and Coco Grande (formed by the bifurcation of the Matuntuvo) Pantano, Pedrito, Pedro, Urabà, Urabacito, Pinchindi, and Pichindicito. In front of them all a formidable sandbank extends outwards, and the mouth of each is obstructed by a bar formed by the deposition of alluvial matter. Within the bar the depth averages 50 to 60ft. The Tarena is the widest and deepest, and follows the general course of the main stream, running N., and is thence called the Rio Madre, or mother river. It averages 40ft. in depth, and 500 yards in width, but the bar at its mouth is at times almost dry, and the gulf waves break heavily over it. At its separation from the Barbacoas it is 1,550ft. in width. The latter is 80 yards wide. The Cano Coquito is the most practicable of the channels, but has only from 6 to 12ft. of water for the distance of 4,546 yards above its mouth, and the latter has only from 2 to 4ft. of water on the bar. Dr. Halsted's boat grounded there, though it drew only 3½ft. of water. Its width, moreover, is very small, being only from 25 to 35ft. between the bushes at its sides, and in some spots only 15ft. The mouth of this cano is called in the "Derrotero de las Antillas" (Madrid, 1817), the Faisan Chico, and is thus noticed:—"Of all the mouths, the Faisan Chico offers the greatest advantages. This arm of the river has 3ft. of water on its bar, and the tides rise only 2ft. throughout the whole of the Gulf of Darien." In front of its mouth is a long, low island, called Islat de Muertos, or dead men's island. The hull of the "Stella" and the boiler of a small steamer that was wrecked were visible when Lieutenant Craven surveyed this mouth. In the Candelaria and Pavo channels, Trautwine and Halsted found only 2ft. of water at a quarter of a mile from the shore; and in the Matuntuvo only 3ft. From the mouth of the Sucio, a tributary which rises in the Antioquian chain, and falls into the Atrato about 70 miles up, the current is 3 miles an hour. Near the headwaters there are rapids, and the current is 7 miles an hour.

* Population in 1851, 8,471, mostly negroes. It is a miserable town of mud huts built on swampy ground.

† Fleas' Hill.

THE ATRATO AND SAN JUAN LINE.

This is the most southern and the longest line between the Atrato and the Pacific. Humboldt was told that, in 1788, the curate of Novita, or Citharà, set his flock to work to dig a canal from the San Juan, at the village of San Pablo, to the sources of the Raspadura, which flows into the Quito, an affluent of the Atrato. San Pablo is half-way between Novita and Tado, and about 40 miles N. of Noanamà. By this cut, called the Canal de la Raspadura, it was said that, when the rains were abundant, and the rivers overflowed their banks, an actual water communication existed between the two oceans, and the isthmus was separated from the continent of South America, so that canoes used to pass from one river to the other. But Mr. Trautwine and Dr. Mina B. Halsted, a young physician of New York, who surveyed the pass in 1853, learned, by inquiry at the spot, that the canal never was made, but that canoes had been dragged across. They examined the Santa Monica and the Raspadura, both of which rise in the same ridge, and unite to form the Quito. The head of canoe navigation on the Santa Monica, which is the more practicable, was found to be 103ft. above the San Juan; and the lowest depression of the dividing ridge was ascertained to be 80ft. higher, or 183ft. above the San Juan. The breadth of the isthmus of San Pablo, as the ridge is called, is 3¼ miles. The distance from the Coquito mouth of the Atrato to Santa Monica is 281, thence to San Pablo 3¼, and from San Pablo to Chirambirà, at the mouth of the San Juan, 123 miles. The total distance would, then, be 407¼ miles. The elevation of the ridge above the level of the sea was not ascertained, but it must be very considerable. Mr. J. C. Trautwine, C.E. (in his book, entitled "Inter-oceanic Canal Route," Philadelphia, 1854), reported that a canal by that line would be totally impracticable. It was afterwards surveyed by Mr. Porter and Mr. Lane, who gave the same opinion, and was also examined by Mr. Vincent, of Southwark, with the same result. Mr. Trautwine's book contains interesting views of the Cano Coquito, Quibbò,* San Pablo, Chirambirà, and other places on the Atrato and San Juan.

THE ATRATO, PATO, AND BAUDO LINE.

At the distance of 237 miles above its mouth, the Atrato receives the Pato, the head of which is thirty miles above the confluence. From its head a pass of 1¾ mile, with a summit level of 365ft. above the ocean, leads to the Baudo, which, after a course of eighty miles, falls into the Pacific between Cape Corrientes and the mouth of the San Juan. Its length, 348¾ miles, is less than that of the San Juan route; but Mr. Lane, Mr. Porter, and Mr. Trautwine, each of whom surveyed it separately, found that it had no other superiority over that line.

THE ATRATO, NAPIPI, AND CUPICA LINE.

About 150 miles above its mouth, the Atrato receives the Napipi, and 75 miles above the mouth of the latter is the Tambo (shed) de Antado, which was erected by the Government of New Granada for the convenience of travellers. From thence a path leads over the hill, called Pié de Andé, to the Quebrada (rivulet) del Mar, which is the head of the Cupica, that falls into the Pacific, south of Cape Marzo. The distance from the Tambo to Cupica is sixteen miles. The entire length of the line from sea to sea would therefore be about 241 miles. This route was first noticed in 1799, by Goguenèche, a Biscayan pilot, and was afterwards recommended by Humboldt. In January, 1820, Colonel Cancino, Captain (now General) Tomas Cipriano de Mosquera, Captain Joaquin Andre, and Senor Deserein were conveyed from Bueventura to Cupica, in the Chilian frigate "Andes," the commander of which, Captain Illingsworth, had a six-oared launch dragged across to the Napipi in ten hours, the crew cutting the bush as they advanced. The above officers and the doctor of the frigate then descended in her to the village of Murri, on the Atrato, whence, General Mosquera told the author, they drove away the Spaniards. This launch was in a shed at Quibdò when Captain Cochrane visited that place in 1824. An account of the above excursion was given on the 20th of May, 1834, in the "Reverberacion Mercantil del Atrato," a paper edited by Senor Cardenas, one of the victims who perished in the "Amazon," on the 4th of January, 1852. Dr. Florentino Gonzales and Cardenas had received a concession for a canal by this route, and Eliot Warburton was going out with the latter to the Atrato mouth, where he erroneously supposed that the Scotch colony of Darien had been located.

In 1827, Lieutenant Charles Friend, R.N., crossed from the Napipi to Cupica and back, having ascended the Atrato in the little steamer "Libertador." About the year 1843, Louis Phillippe and Guizot sent J. F. Landreau, M.D., to examine and report upon this line; but, as Dr. Landreau went thence to the province of Esmeraldas, in Ecuador, where he discovered three mines of gold and one of platina, and settled, his report was, probably, unfavourable. In 1848, Commander Wood, of the "Pandora," walked in a few hours from the Cupica to the Napipi and back. However, from the examination made by Don Juan de Dios Ulloa, a Granadian engineer, and the surveys afterwards made by Mr. Trautwine and Dr. Halsted, and then by Messrs. Kennish, Nelson, Rude, and Dr. Jameson, it appears that the dividing ridge is of such an elevation (about 500ft.) and breadth, that a tunnel about 6½ miles in length would be necessary. Cupica Bay, moreover, is small, and only an open roadstead, and the obstacles presented by the bars and sandbanks at the mouths of the Atrato are most formidable. Mr. Trautwine estimated the cost of a canal by this line at 325,000,000 dollars.

(To be continued.)

* Dò ortdor, in the language of the Choco Indians, like tee in that of the Darien Indians, signifies a river: thus, Quibdo means river of gravel; Murindo, of mud; Munguido, of mosquitoes.

NEW MUZZLE-LOADING FIELD GUNS.†

OUR readers are doubtless aware that most of our field pieces are Armstrong breech-loading guns. We are not aware that any serious objection has ever been urged against Armstrong breech-loaders up to and not exceeding what is known as the 40-pounder in dimensions, but it is certain that they possess no peculiar advantage over the muzzle-loading rifled guns of the same size. These last, indeed, can be loaded more rapidly, and they are obviously less complicated and less liable to get out of order than any Armstrong gun. Armstrong lead-coated shot, too, sheds the soft metal by a curious and not very well understood process of decomposition while lying in store. It has been decided, therefore, to revert, tentatively at least, to the old muzzle-loading system, and on January 16, last, experiments were carried out with three new guns, in order to determine the best pitch, &c., for the rifling. As the new guns are likely to play an important part in our future armaments, we feel pleasure in being able to place before our readers an illustration showing their general appearance very accurately, but we do not feel ourselves at liberty to publish drawings of the rifle groove; therefore we give the gun in external elevation only. The typical gun is 3in. bore, and the three pieces tested at Shoeburyness differed only in the rifling from each other. No. 1 has three grooves and a twist of one turn in 75in.; No. 2 has three grooves and one turn in 90in.; and No. 3 has but two grooves, making one turn in 75in. All the grooves are rounded, and 0·4in. wide by 0·1in. deep. The shells for these guns are 9·5in. long, and contain a bursting charge of half a pound of powder. The result of the trials was as follows:—No. 1 gun gave a minimum range of 1,296 yds., and a maximum range of 1,357yds., the deflection of the projectile being, maximum 2·5yds., minimum ·4yds. For No. 2 the maximum range was 1,422yds; the

Digitized by Google

minimum, 1,324yds.; maximum deflection, 5.2yds.; minimum, 4yds. No. 3 gun; maximum range, 1,431yds.; minimum, 1,349yds.; maximum deflection, 5yds.; minimum, 1·4yds. The charges were, in all cases, one-seventh of the weight of the projectile, or 11b. 11oz., from which it appears that No. 2 gave rather better results than either iof the others. The guns are made of wrought ron, with steel tubes, and will prove very much less costly, and more durable in service than the Armstrong breech-loader.

PRACTICAL NOTES ON GREEK FIRE.

By Mr. John Horsley, F.C.S.

THIS preparation is altogether a misnomer, as the original Greek fire was simply a fire-ball made of various combustible materials, which was thrown in an ignited state into an enemy's camp, whereas the so-called Greek fire is a solution of phosphorus in a very volatile spirit known as bisulphide of carbon, which when sprinkled upon substances of a loose or spongy character more or less rapidly produces spontaneous ignition, as may be seen from the following table. The constant temperature of the particular part of the room in which my experiments were made, for a fire was burning at the other end, was 55deg. Fah.:—

Paper ignited in.....	1 min.	Packing or sail cloth	2 min.
Wood shavings	1½ „	Woollen cloth	5 „
Linen.....	1½ „	Carpet.....	6 „

At higher temperatures of course the ignition would be much quicker (summer weather, for instance), as phosphorus instantly fires when a direct heat of 70deg. is applied to it, and the slightest friction with the finger in its dry state produces a serious burn which heals with difficulty. I, therefore, particularly caution persons against meddling with it under any circumstances. Atmospheric changes, such as cold and damp weather, appear to exercise a considerable influence over phosphorus in checking or retarding its ignition, hence it is that the application of liquid phosphorus to paper and other light substances will not then inflame them so quickly as when the weather is warm and dry, as I have now satisfactorily ascertained; for even at a temperature of 47deg. some of the articles mentioned above took a considerably longer time to ignite, but the day, however, was very wet, and there was no fire in the room during the time of conducting the experiments, thus:—

Paper required.....	6 min.	Linen	20 min.
Wood shaving.....	7 „	Woollen cloth.....	34 „
Packing or sail cloth	11 „	Carpet	45 „

So that although no spontaneous combustion follows the use of Greek fire or liquid phosphorus in the open air on a cold or damp day, it is nevertheless quite as much, if not more dangerous than if it had succeeded, as the slightest heat or friction, either by the hands or feet, on a part containing phosphorus would readily inflame it like an ordinary lucifer match, and in the case of a female, her long clothes might be speedily set on fire. In a warm room the danger would be even greater still, therefore the utmost caution should be used in walking about or handling any article of furniture. The peculiar smell of phosphorus would at once indicate the fact of its having been used at all, and if white fumes are being evolved, say from a carpet, instantly proceed to wet it with water to prevent its ignition, cut out the spot, and throw it into the yard to dry and be burnt; the same with curtains, bed clothes, &c.; in fact, this is the only way of getting rid of any danger. In proof of cold retarding ignition I placed in the open air on the window ledge of the laboratory, the temperature being 35deg. Fah., a small saucer containing some shavings sprinkled with liquid phosphorus. Several hours elapsing without any visible effect, the saucer was brought just inside the room, when the shavings instantly inflamed.
